THE EDITORS

SIR DONALD MACKENZIE WALLACE, K.C.I.E., K.C.V.O.

ARTHUR T. HADLEY, LL.D., PRESIDENT OF YALE.

HUGH CHISHOLM, B.A. (FORMERLY SCHOLAR OF C.C.C. OXFORD)

THE DEPARTMENTAL EDITORS

FOR LAW AND GOVERNMENT:
THE HON. SIR JOHN SCOTT, K.C.M.G., Deputy Judge-Advocate-General.

FOR MILITARY AFFAIRS:
SIR GEORGE SYDENHAM CLARKE, K.C.M.G., F.R.S.

FOR MEDICAL SCIENCE:
D. NOEL PATON, M.D., B.SC., F.R.C.P.ED.

FOR THEOLOGY:
REV. W. E. COLLINS, M.A., Prof. of Ecclesiastical Hist. at King's Coll., Lond.

FOR MINING:
HENRY M. HOWE, A.M., Prof. of Metallurgy at Columbia University.

FOR BOTANY:
D. H. SCOTT, M.A., PH.D., F.R.S., Hon. Keeper, Jodrell Laboratory, Kew.

FOR GEOGRAPHY AND STATISTICS:
J. SCOTT KELTIE, F.S.S., F.S.A.SCOT., LL.D., Sec. Roy. Geog. Soc.

FOR ASTRONOMY:
SIMON NEWCOMB, PH.D., LL.D.

FOR MATHEMATICS:
JOSEPH LARMOR, M.A., D.SC., SEC.R.S., University Lecturer in Mathematics, Cambridge.

FOR ELECTRICITY:
J. A. FLEMING, M.A., D.SC., F.R.S., Prof. of Electrical Engineering, Univ. Coll., London.

FOR ART:
M. H. SPIELMANN, Editor of the *Magazine of Art.*

FOR ZOOLOGY:
G. HERBERT FOWLER, PH.D.

FOR NAVAL AFFAIRS:
JAS. RICHARD THURSFIELD, M.A.

FOR BIOGRAPHY:
RICHARD GARNETT, C.B., LL.D.

FOR LITERATURE:
EDMUND GOSSE, LL.D.

FOR ECONOMICS:
WYNNARD HOOPER, M.A.

FOR RAILWAYS:
MAJOR HENRY G. PROUT, Editor of *Railroad Gazette*, N.Y.

FOR MUSIC:
J. A. FULLER MAITLAND, M.A., F.S.A.

FOR GAMES AND SPORTS:
ALFRED WATSON, Editor of the *Badminton Library.*

THE ASSOCIATE EDITORS

PHILIP A. ASHWORTH, DR. JUR.
H. M. ROSS, B.A.
FRANKLIN H. HOOPER, A.B.
E. H. WILLIAMS, M.D.

THE SUB-EDITORS

JAMES A. MANSON.
G. B. LYNES, A.M.

ENCYCLOPÆDIA BRITANNICA.

VOLUME XXIX (GLARUS–JUTLAND).

PRINCIPAL CONTENTS.

PREFATORY ESSAY: THE APPLICATION OF THE DOCTRINE OF EVOLUTION TO SOCIOLOGICAL THEORY AND PROBLEMS. BENJAMIN KIDD.

GLASS. HARRY J. POWELL, Author of "Principles of Glass-Making"; *Stained*, LEWIS F. DAY, Examiner for Art, Board of Education; Author of "Windows—Stained and Painted Glass," &c.

GNEIST. PHILIP A. ASHWORTH, Dr. Juris (Würzburg), Translator of Gneist's "History of the English Constitution."

GOLD. J. HAYS HAMMOND, A.M., Consulting Engineer to the Consolidated Gold-fields of South Africa, British South Africa Company, &c.

GOLD COAST. H. E. EGERTON, Author of "A Short History of British Colonial Policy," &c.; *Ashanti Expedition*, Sir GEORGE SYDENHAM CLARKE, K.C.M.G., F.R.S., Governor of Victoria, and FRANK R. CANA, F.R.G.S., Author of "Traveller's Companion and Guide."

GOLF. H. G. HUTCHINSON, Author of "Golf" in Badminton Library, "Book of Golf and Golfers," &c.

GONCOURT, E. and J. DE. ARTHUR SYMONS, Assistant Librarian, British Museum; Author of "Studies in Two Literatures."

GORDON. Colonel C. M. WATSON, C.M.G., Deputy-Inspector-General of Fortifications.

GOSPELS. The Rev. V. H. STANTON, D.D., Ely Professor of Divinity, Cambridge University.

GOUNOD. ARTHUR HERVEY, Author of "Masters of French Music."

GRAIN TRADE OF THE WORLD. G. J. S. BROOMHALL, Editor of the "Corn Trade Year-Book."

GRANT, PRESIDENT. JOHN FISKE, LL.D. (the late), Author of "The Discovery of America," "The Mississippi Valley in the Civil War," &c.

GRAY, ASA. C. W. ELIOT, LL.D., D.C.L., President of Harvard University.

GREECE. *Geography, Statistics, &c., Recent History, and Literature*, J. D. BOURCHIER, M.A., Correspondent of "The Times" at Athens; *Greco-Turkish War*, Sir GEORGE SYDENHAM CLARKE, K.C.M.G., F.R.S.

GREEN, J. R. The Rev. WILLIAM HUNT, M.A., Author of "The Church of England in the Middle Ages."

GREEN, T. H. W. H. FAIRBROTHER, M.A., Author of "The Philosophy of T. H. Green."

GREENLAND. FRIDTJOF NANSEN, Author of "Farthest North."

GREY, SIR GEORGE. The Hon. W. PEMBER REEVES, Agent-General for New Zealand.

GREY, EARL. RICHARD GARNETT, C.B., LL.D.

GROUPS, THEORY OF. WILLIAM BURNSIDE, F.R.S., Professor of Mathematics, Royal Naval College, Greenwich.

GUARANTEE. H. A. DE COLYAR, Barrister-at-Law, Author of "The Law of Guarantees and of Principal and Surety."

GUATEMALA. W. W. ROCKHILL, Head of the Bureau of American Republics, and C. E. AKERS.

GUIANA. I. P. A. RENWICK, M.A., Assistant Editor of the "Statesman's Year-Book"; *British*, F. CUNDALL, Secretary of the Institute of Jamaica; *Dutch*, C. M. KAN, Professor of Geography, University of Amsterdam; *French*, PAUL LOUIS.

GUN. H. SETON-KARR, M.P.

GUN-MAKING. A. G. HADCOCK, Manager of Gun Department, Elswick Works.

GUNNERY. A. G. GREENHILL, F.R.S., Professor of Mathematics, Ordnance College, Woolwich.

GURNEY, EDWARD. ANDREW LANG.

GYMNOSPERMS. A. C. SEWARD, F.R.S., Lecturer in Botany, Cambridge University.

GYROSCOPE. Professor A. G. GREENHILL.

HALOS. P. G. TAIT (the late), Professor of Natural Philosophy, Edinburgh University.

HAMBURG. J. T. BEALBY, Joint-Author of "Stanford's Compendium: Europe."

HANCOCK, GENERAL. F. H. HOOPER, formerly Assistant Editor of "The Century Dictionary."

HARRISON, PRESIDENT. The Hon. JOHN W. FOSTER, LL.D., U.S. Secretary of State, 1892–93.

HAUSSMANN. THOMAS SECCOMBE, formerly Assistant Editor of the "Dictionary of National Biography."

HAWAIIAN ISLANDS. H. D. ALEXANDER, Honolulu; Author of "A Brief History of the Hawaiian People."

HAYES, PRESIDENT. The Hon. CARL SCHURZ, LL.D., U.S. Secretary of the Interior, 1877–81.

HAYWARD. THOMAS SECCOMBE.

HELMHOLTZ. J. G. M'KENDRICK, M.D., F.R.S., Professor of Physiology, Glasgow University.

HEMICHORDA. G. HERBERT FOWLER, Ph.D.

HERAT. Sir T. H. HOLDICH, K.C.I.E., C.B.

HEREDITY. P. CHALMERS MITCHELL, D.Sc., F.Z.S., Lecturer on Biology at the London Hospital Medical College.

HERONDAS. W. G. HEADLAM, Fellow of King's College, Cambridge.

HERSCHELL. M. H. CRACKANTHORPE, K.C., D.C.L.

HIMALAYA, HINDU KUSH. Sir T. H. HOLDICH, K.C.I.E., C.B.

HINDU LAW. Sir WILLIAM MARKBY, K.C.I.E., D.C.L., formerly Reader in Indian Law, Oxford University.

HIPPOLYTUS. The Rev. LEIGHTON PULLAN, Fellow of St John's College, Oxford.

HOGARTH. AUSTIN DOBSON.

HOLL, FRANK. F. G. STEPHENS, formerly Art Critic of the "Athenæum."

HOLLAND. *Geography and Statistics*, Professor C. M. KAN; *Political History*, H. TIEDEMANN; *Literature*, EDMUND GOSSE, LL.D.

HOLMES, O. W. JOHN T. MORSE, Jr., sometime Lecturer in History, Harvard University; Author of "The Life and Letters of Oliver Wendell Holmes."

HOMŒOPATHY. WILLIAM TOD HELMUTH, M.D. LL.D. (the late), sometime President of the American Institute of Homœopathy.

HONG KONG. H. E. EGERTON, M.A.

HOPS AND HOP-GROWING. WILLIAM FREAM, LL.D., F.G.S., Lecturer on Agricultural Entomology, Edinburgh University.

HORSE-RACING. A. E. T. WATSON, Editor of the Badminton Library; Author of "The Turf," &c.

HOSPITALS. Sir HENRY BURDETT, Author of "Hospitals and Asylums of the World."

HOTTENTOTS. Professor A. H. KEANE.

HUGO, VICTOR. A. C. SWINBURNE.

HUMBERT, KING. H. WICKHAM STEED, Correspondent of "The Times" at Rome.

HUNGARY. *Geography and Statistics*, J. VON JEKELFALUSSY, Dr. Juris (the late), Director-General of the Royal Hungarian Statistical Bureau; *Literature*, EMILE REICH.

PREFATORY ESSAY.

THE APPLICATION OF THE DOCTRINE OF EVOLUTION TO SOCIOLOGICAL THEORY AND PROBLEMS.

By Benjamin Kidd.

IN the Prefatory Essay to vol. xxvi. of the present edition of the *Encyclopædia Britannica,* Mr Edward Dicey, in reviewing recent political progress, has described the tendencies in thought and statecraft during the last quarter of the 19th century as, on the whole, most adequately summarized in the phrase "Conservative reaction." It is evident that a situation in the public life of a period to which such an expression can be correctly applied has a significance which extends beyond the conditions of current politics. Judging from analogies in history, a position of the kind in political life must be taken to imply that great alterations in the habits of thought and in the opinions of society are in progress beneath the surface of events. Such changes must arise from causes which are deep-seated, which are possibly carrying us forward to a new era of reconstruction, and which, therefore, fall to be considered in wide and general relations.

A new influence in the study of man.

During the second half of the 19th century the cause which most considerably influenced the tendencies of thought was the acceptance of the doctrine of organic evolution as based on the principle of natural selection. As it has come to be understood that it is not so much in the lower animal world as in human society that we have the highest, most complex, and most characteristic phase of the struggle for existence, a new influence, against which the older tendencies in knowledge have continued to struggle with diminishing success, has been felt in all the sciences dealing with man and the phenomena of his social progress. The leading problems in ethics, in politics, in economics, in religion, and in philosophy have been brought into direct relationship to principles universal in reach, which are seen to affect them vitally, but which were, nevertheless, not understood nor even to any general extent discussed before the closing decades of the 19th century. The first effect of the new ideas has been profoundly disintegrating. There has resulted an attitude of doubt, of hesitation, and of apparent reaction as the tendencies of the less organic views of older schools of thought have become visible. The process of change in progress is, in short, radical and far-reaching, and the first duty of the observer is, therefore, to endeavour to see it as a whole.

Although the hypothesis of evolution as applied to the cosmos, and even in a more special and local sense to forms of life, is not new, the effort to consider it in relation to man himself, and consequently in its bearings on sociological theories and problems, is of quite recent origin. To understand the nature of the characteristic difficulties which have presented themselves in this attempt, the conditions prevalent in Western thought when Charles Darwin published the *Origin of Species* in 1859 must be recalled.

For a hundred years before Darwin—that is to say, during the last half of the 18th century and the first half of the 19th century—the general mind had been to some extent familiarized with the conception of continuous development by many speculations which had begun to be supported by evidence. Kant's nebular hypothesis, after it had received scientific shape at the hands of Laplace and Sir W. Herschel, prepared the world for the reception of the theory of evolution as applied to the physical universe. In the biological sciences ideas of development and progressive modification of forms were also to be found in many quarters. In France by the middle of the 18th century Buffon had suggested that a succession of nearly related forms was to be traced amongst animals and plants, likeness of type being held by him to suggest the possibility of the varying forms being considered as having sprung originally from a single stock. Lamarck and Geoffroy Saint-Hilaire in the same country had arrived at a similar conclusion, the latter asserting that such divisions as fishes, amphibians, birds, and mammals were formed on one original type, and that modifications were still in progress. Lamarck in the *Philosophie Zoologique* had held, although in opposition to the dominant influence of Cuvier, that forms of existing life were descended from one or more original forms; the theory being also put forward by him that the action of the physical environment of the various forms in causing the increasing use or disuse of organs had tended to produce development in certain directions with divergence of type.

Earlier theories leading up to natural selection.

In Germany and England thought had been moving in the same direction. In the former country Kant's speculations as to the mode of development of the solar system had been supplemented by a view of evolution in the organic world which still forms a connecting link between the past and the modern view. The ideas of Goethe and Oken had tended to strengthen a belief in the theory of progressive development in life; and the work of embryologists like Wolff, Meckel, and von Baer had given a decided impetus to speculations founded on it. Meckel had remarked in 1811 that "there is no good physiologist who has not been struck incidentally by the observation that the original form of all organisms is one and the same," and von Baer in 1834 had asserted in still more decisive words that "only in a very childish view of nature could species be regarded as permanent and unchangeable types." In England to a certain class of inquirers a number of causes had long contributed not only to suggest the idea of continuous development, but to call attention to the character of the forces which might influence it. As early as 1798 Malthus, confining his attention to human society, had published his famous *Essay on the Principle of Population*, which was afterwards to suggest to Darwin the conception of natural selection. In geology a group of active minds had been working out the history of life upon the globe from the stratified rocks. The contributions of Murchison, Buckland, Mantell, Lyell, and others had helped to familiarize men's minds with the idea of development, both physical and biological, in the past history of the earth, Lyell, in particular, seeking to uphold the theory that all the geological features of the world were to be accounted for by the agency of exactly the same kind of changes as were taking place upon the earth in the present time.

In spite, however, of all these and other important indications, and of many pregnant suggestions made by observers like Owen, Wells, Matthew, and others, it must be considered that the conception of the continuous evolution of life from simpler forms had made surprisingly little impression. It had to contend against a set of conditions which it is important to understand, conditions that not only retarded its more direct developments, but prevented altogether its application to the higher problems of biology presented in human society.

Antagonism to the evolutionary principle.

In the first place, there was everywhere to be distinguished a strongly entrenched resistance to all attempts to apply the doctrine of evolution to man himself. The outlying conclusion upon which this resistance had generally elected to make its decisive stand was a very clear one. It was suggested in the first instance by the hitherto prevailing interpretation of the Hebrew account of creation contained in the first book of Genesis. But the principle which it involved was undoubtedly established in its hold on the more thoughtful minds simply by the absence of any convincing theory of the mechanism by which a process of evolution could be accepted as operating in life. It might be possible, it was reasoned, to accept divergences in forms of life within certain limits (variations). Nevertheless, it was said, species

must, at the same time, be held to be immutable. These it was considered represented acts of creation (special creations) at various times in the past history of the earth. Buffon's theory of organic evolution had been hardly more than suggestive. Lamarck had put forward a theory of the accumulation of the supposed inherited effects of the use and disuse of organs to account for divergence of types. But his view had not been accepted; and his conception of the transmutation of species was ridiculed in France by Cuvier, the most influential of the systematic naturalists, who remained to the end an advocate of the theory of constant cataclysms and recurring creations in the past history of life. Finally, it is on record, on the authority of Darwin, that down to the publication of the *Origin of Species* "all the most eminent living naturalists and geologists disbelieved in the mutability of species." It came to be afterwards asserted, he said, speaking of the position at the publication of the *Origin of Species*, that the subject was in the air, or that men's minds were prepared for it; but he continued, "I do not think that this is strictly true, for I occasionally sounded not a few naturalists, and never happened to come across a single one who seemed to doubt about the permanence of species. Even Lyell and Hooker, though they would listen with interest to me, never seemed to agree."

This was the position in thought when Darwin published the *Origin of Species*. It is necessary to keep it in view in considering the later applications of the theory of evolution to sociological problems. At first sight the *Origin of Species* attempted nothing in itself very remarkable.

Significance of the "Origin of Species."

It endeavoured to prove an assertion which, as has been said, had been many times put forward by naturalists in the past, namely, that species were not fixed groups. In estimating the nature of the work which he considered he had accomplished in the *Origin of Species*, Darwin said, "Hereafter we shall be compelled to acknowledge that the only distinction between species and well-marked varieties is, that the latter are known, or believed, to be connected at the present day by intermediate gradations, whereas species were formerly thus connected." That was all. Never, however, was a meaning of such far-reaching application hidden in a simpler form of words. It was by formulating in the conception of natural selection a theory of the mechanism by which he conceived the transmutation of species to be effected, and then, and especially, by supplying the necessary evidence in support of it, that Darwin advanced the doctrine of evolution beyond the position to which any of his predecessors had carried it.

The general mind from the beginning, and perhaps in some senses more fully than the workers in many of the departments of biological science, distinguished the significance of the new departure. It was not simply that a unifying principle exemplifying the mode of change in the organic world had been enunciated. What was perceived was that, by implication, the study of man himself had become a department of higher biology. All the phenomena of his development—physical, mental, and social—had now been brought within the application of the general causes which were thus asserted to have controlled the evolution of life from lower to higher forms from the beginning of sentient existence.

It will probably be seen much more clearly in the future than it is at present, how great were the difficulties which at the outset confronted the attempt to apply this theory of evolution to sociological problems. When the character of our civilization as a whole is considered; when the nature of the beliefs and of past interpretations of many doctrines intimately interwoven with its history is held in mind; when the fact that the acceptance of the theory of evolution has involved the conception of development as applied to men's fundamental convictions in such matters as ethics, politics, and religion, is taken into account;—it will be seen that an enormous and even an unprecedented change in the habits and modes of thinking of society has been involved. Every allowance must, therefore, be made for tendencies which have hitherto retarded the legitimate application of the conception of evolution to sociology. The wonder rather is that so great progress has already been made, and that, as Romanes has pointed out, we are already, as the result, living in the midst of a revolution in the general tendencies of knowledge which is without a parallel in the past history of mankind.

Looking at the conception of organic evolution as it was accepted in the period immediately following the publication of Darwin's *Origin of Species*, there are several matters which call for attention in considering the subsequent history of the attempt to apply the theory to sociological development.

When the distinctive Darwinian contribution to the doctrine of development is considered, it may be seen to consist essentially in a chain of evidence brought forward to support a simple theory of the mechanism of the evolutionary process. It was proved in the first place that every existing form of life tends to increase at such a rate as to outrun the conditions of its existence for the time being. There is to be found, said Darwin, "no exception to the rule that every organic being naturally increases at so high a rate, that, if not destroyed, the earth would soon be covered by the progeny of a single pair." In the second place, it was found that this faculty in life was coexistent with an inherent tendency in every form to variation within narrow limits. These variations extended to every part, organ, and function, and tended to be transmitted by inheritance. From these facts, now accepted practically without question, there was deduced the principle of natural selection. In Darwin's words, "As many more individuals of each species are born than can possibly survive; and as, consequently, there is a frequently recurring struggle for existence, it follows that any being, if it vary however slightly in any manner profitable to itself, under the complex and sometimes varying conditions of life, will have a better chance of surviving, and thus be *naturally selected.* From the strong principle of inheritance, any selected variety will tend to propagate its new and modified form." As Alfred Russel Wallace put it—the best equipped would have an advantage over their competitors in the struggle for existence, the fittest would survive. And they would tend to transmit in cumulative degree the qualities upon which that fitness depended.

First applications of the theory of evolution to human society.

The first era of the attempt to apply this conception of evolution by natural selection to society extends practically over nearly the whole of the second half of the 19th century; for Herbert Spencer, who had begun his system of social philosophy before the publication of the *Origin of Species,* incorporated in his general system the doctrine of natural selection, which he had himself in some degree foreshadowed in an essay published as early as 1852 in the *Westminster Review.* This first stage of the attempt has gradually brought into view a position of considerable interest in sociological theory, which, as its bearing becomes understood, is likely, it appears to the present writer, to exercise a not unimportant influence on the further development of the theory of organic evolution in general.

The characteristic action of Natural Selection in society.

It is evident that in considering the application of the principle of natural selection to human society there is a fact, encountered at the outset, which is so fundamental that it must be held to control all the phenomena of social evolution. It is nowadays a commonplace of knowledge, that the potential efficiency of society must always be taken to be greater than the sum total of the potential efficiency of all its members acting as individuals. This arises from the fact, to be observed every day in life, of the effect of organization, of division of labour, of specialization of work, and more particularly of the opportunity afforded in an organic type of society for the accumulation and transmission of that knowledge and experience from which power and efficiency in the struggle for existence in a large degree arise. There follows, however, from this fact, obvious enough once it is mentioned, an important inference. This is that in the evolution of society natural selection will, in its characteristic results, reach the individual not directly, but through society. That is to say, the interests of the individual *quâ* individual must cease to be a matter of first importance. It is by development in the individual of the qualities which will contribute most to the efficiency of society, that natural selection will in the long-run produce its distinctive results in human evolution. It is, in short, about this function of socialization, involving the increasing subordination of the individual, that the continued evolution of society by natural selection must be held to centre. Societies in which the individuals were able to resist the process would quickly reach the limits of their progress, and would have to give way in the struggle for existence before others in which the process of subordination continued. In the end it would be the social organizations in which the interests of the individual were most efficiently included in and rendered subservient to the interests of society considered collectively that, from their higher efficiency, would be naturally selected. In all the first attempts, therefore, to apply the doctrine of evolution to social development it was recognized that society must be considered in some sense as organic.

One of the earliest attempts to approach the study of social evolution from this standpoint was made

by Herbert Spencer in the middle of the 19th century. It was contained in an article published in the *Westminster Review* in January 1860, and was entitled "The Social Organism." This article is in many respects one of the most noteworthy documents in the literature of the last half of the 19th century. It is important for two principal reasons. In the first place, it offers the clue to the central principle round which Mr Spencer afterwards constructed his system of social philosophy, and round which the thought, and even the political development, of more than half a century have revolved. In the second place, it clearly expresses the nature of the fundamental difficulty underlying Mr Spencer's attempt to apply the doctrine of evolution to society. It affords, as we read it now, clear indication of a leading cause which made the last quarter of the 19th century a period of apparent reaction, but which, as the application of the doctrine of evolution is better understood, is not unlikely to render the ensuing period one of profound reconstruction in which the science of society may be carried considerably beyond the position reached by Mr Spencer.

Herbert Spencer's sociology.

Mr Spencer's object in the essay in question was suggested by the position which had been reached in the sciences dealing with life. He set out, therefore, by assuming that in the light of the recent great generalizations of biology it had become possible to apply the conception of the social organism much more effectively than was the case in the speculations of Plato and Hobbes. He proceeded accordingly to examine the analogy which he considered existed between the social organism and a living individual body. Mr Spencer in the result found societies to agree with individual organisms in four conspicuous peculiarities, which he enumerated as follows:—

1. "That commencing as small aggregations, they insensibly augment in mass: some of them eventually reaching ten thousand times what they originally were."
2. "That while at first so simple in structure as to be considered structureless, they assume, in the course of their growth, a continually-increasing complexity of structure."
3. "That though in their early, undeveloped states, there exists in them scarcely any mutual dependence of parts, their parts gradually acquire a mutual dependence; which becomes at last so great that the activity and life of each part is made possible only by the activity and life of the rest."
4. "That the life and development of a society is independent of, and far more prolonged than, the life and development of any of its component units; who severally are born, grow, work, reproduce, and die, while the body politic composed of them survives generation after generation, increasing in mass, completeness of structure, and functional activity."

In the examination of these analogies Mr Spencer, as might be expected, found in society, as in the individual organism, physiological division of labour; "differentiation upon differentiation taking place in the evolution of a civilized society," with the development of government, of control, of communication, and economic activities of all kinds.

Coming then to the differences between societies and individual organisms, Mr Spencer proceeded to enumerate these also under four heads The differences under the first three of these need not here be referred to, as they were in large measure explained away in the essay. But under head 4 a noteworthy distinction was made. Mr Spencer continued:—"The last and perhaps the most important distinction, is, that while in the body of an animal, only a special tissue is endowed with feeling; in a society, all the members are endowed with feeling. . . . While in individual bodies, the welfare of all other parts is rightly subservient to the welfare of the nervous system, whose pleasurable or painful activities make up the good or evil of life; in bodies politic, the same thing does not hold, or holds to but a very slight extent. It is well that the lives of all parts of an animal should be merged in the life of the whole; because the whole has a corporate consciousness capable of happiness or misery. But it is not so with a society; since its living units do not and cannot lose individual consciousness; and since the community as a whole has no corporate consciousness. *And this is an everlasting reason why the welfare of citizens cannot rightly be sacrificed to some supposed benefit of the State; but why, on the other hand, the State is to*

be maintained solely for the benefit of citizens. The corporate life here must be subservient to the lives of the parts; instead of the lives of the parts being subservient to the corporate life."

When the sentences which are here printed in italics are read carefully their importance will be perceived. They bring clearly into view the nature of the limitation within which Mr Spencer constructed his system of social philosophy. They afford also the clue to the characteristic conception of society which, although it has not been at any time without vigorous opposition, has been in the ascendant during the whole of the first stage of the attempt to apply the doctrine of evolution to society.

Spencer's limitation.

It has been said that in considering the principle of natural selection as in operation in society there is a principle to be taken into consideration at the outset which is so fundamental in character that it ultimately controls all the phenomena of social development. From the fact that the efficiency of society is always greater than the sum total of the efficiency of all its members acting as individuals, natural selection, it has been pointed out, must in its characteristic effects in human evolution reach the individual through society. It must, in short, in the end subordinate the individual and all his interests to the efficiency of society in this higher sense. But in the passage just quoted from Mr Spencer, as indeed in the whole of the article in question, two facts, it may be observed, call for attention. The "social organism" which he has in view is the State. And the State as he conceives it is subordinate to the individual, and not the individual to the State. In Mr Spencer's own words, "the corporate life here must be subservient to the lives of the parts; instead of the lives of the parts being subservient to the corporate life.

The difficulty with which Mr Spencer was here confronted may readily be perceived. If natural selection is conceived as operating on society, and, therefore, as tending to produce the highest efficiency out of the materials that comprise it, it must, as has been said, produce the subordination of the interests of its units to that higher efficiency of society which is greater than the sum total of the efficiencies of its component members. But one of only two conclusions could, therefore, result from Mr Spencer's position. In regarding the "social organism" as an organism in which the corporate life must be subservient to the lives of the parts, instead of the lives of the parts being subservient to the corporate life, it must be that the individual had succeeded in arresting the characteristic effects of natural selection on society. Or else, the result just mentioned being scarcely conceivable, natural selection, whether the individual be conscious of it or not, *must* be subordinating individual interests in society to a larger meaning in the evolutionary process. Society must, in short, be subject to principles which reach farther than Mr Spencer conceived; it must be organic in some different and wider sense than he imagined; and the analogy of the "social organism" as confined within the consciousness of ascendant interests in the political State must be considered to be a false one.

This may be said to present the crux of the position which slowly developed itself during the first stage of the attempt to apply the doctrine of evolution to society. The main problem with which the philosophy of the race has been on the whole always concerned, namely, that the individual in society is being subordinated to a process the principles of which extend beyond his political interests, and that this subordination must, nevertheless, be effected in terms of his own mind, had not been touched. Mr Spencer, notwithstanding the reach of the principle he was stating (see the article in these volumes on SOCIOLOGY), had not in practice got farther than the English Utilitarians, from Bentham to John Stuart Mill, in regarding the science of society as the science of the ascendant interests of the individuals comprised within the consciousness of the political State. As the 19th century reached its closing decade the gradually increasing perception of the difficulties of such a position is, therefore, to be distinguished in all directions,—in ethics, in economics, in politics, as well as in general philosophy. The conviction that it was impossible to formulate the principles of human development in the terms of any theory of the ascendancy of the interests of society as confined within the consciousness of Mr Spencer's "social organism," had indeed not ceased in the meantime to be ably and consistently expressed in various idealist and other schools of thought. But what now began to be clear was that the same conclusion must ultimately prevail in quarters where it was held

Dominant influence of English Utilitarians.

that there must be no implication to go a step beyond that firm ground of fact and experience demanded by the representatives of the characteristic development in English thought which had come down through Hume. Many of the theories and anticipations of the Utilitarian school in philosophy and politics were, in short, felt to have no permanent foundation, and their influence began to diminish. The extreme expression which the Utilitarian position had reached in phases of continental socialism, and in particular in the theories of Marx, in which the economic factor was asserted to be the ruling factor in history, were seen to be all involved in a like condemnation. The century, accordingly, approached its close in a period of apparent reaction. And the chill shadow of the waning credit of the over-confident ideas of the Utilitarian school which had ruled the development in thought and politics in its middle decades hung heavily over all the progressive parties which had inherited the traditions to which these ideas had given rise.

As the general theory of evolution had in the meantime continued to develop, other symptoms of interest bearing on the position which had been defined in sociological theory had become visible, and call for notice. The Darwinian doctrine of evolution as a working hypothesis rested on natural selection as the efficient cause of progress in the development of life. The theory of natural selection which Darwin had formulated had, however, been suggested to him, not so much by observations of the lower forms of life as by a study of human society. "Fifteen months after I had begun my systematic inquiry," says Darwin, "I happened to read for amusement Malthus *On Population*, and being well prepared to appreciate the struggle for existence which everywhere goes on from long-continued observation of the habits of animals and plants, it at once struck me that under these circumstances favourable variations would tend to be preserved, and unfavourable ones to be destroyed. The result of this would be the formation of new species. Here, then, I had at last got a theory by which to work." The co-formulator of the principle of natural selection, Alfred Russel Wallace, speaks of his independent experience in almost the same terms. "I was led to the theory itself," he said, "through Malthus—in my case it was his elaborate account of the action of 'preventive checks' in keeping down the population of savage races to a tolerably fixed but scanty number. This had strongly impressed me, and it suddenly flashed upon me that all animals are necessarily thus kept down—'the struggle for existence'—while *variations*, on which I was always thinking, must necessarily often be *beneficial*, and would then cause those varieties to increase while the injurious variations diminished."

Influence of Malthus.

A truth since in evidence in the development of the theory of organic evolution had here received exemplification, namely, that it is in human society that there is presented to the inquirer the principal basis for the study of the phenomena of life. Man is really the animal which has been observed most, the creature of whom immeasurably more is known than of any other form of existence. Many departments of knowledge and entire professions are exclusively devoted to the study of the phenomena of his life, both individual and social; and all history and literature are but the record of his actions and emotions in the struggle which he maintains against his fellows and against the world. It was, therefore, but a natural sequence of events that a unifying principle controlling the development of life should be suggested independently to two observers by a study of the struggle for existence in human society.

The bearing of this fact remained, however, to be seen. The Darwinian doctrine of natural selection which had been applied to life had been suggested, as has been said, by the theory of population propounded by Malthus, a theory closely associated in England with the political philosophy of the Utilitarians. It is accordingly of importance, in view of the developments which were to follow, to note certain features in which the doctrine of evolution, as it was presented by the early Darwinians, was related to the Utilitarian position as it was defined at the time in English thought, particularly in the writings of Bentham and James Mill. The characteristic position of the Utilitarians may be said to be that, even when all due allowance is made for many suggestive passages of wider implication in their writings, they practically conceived all the principles of the development of society to be related to the ascendant interests in the struggle for existence of the individuals comprised within the consciousness of the political State as they saw it around them. They endeavoured, therefore, as it were, to formulate the principles of human evolution from that cross-section of interests

The earlier view a restricted one.

and motives which they dissected into view on an examination of the principles of the State as thus conceived. In the first statement of the law of natural selection the correlative of this position is apparent. There is visible a tendency to endeavour to enunciate the laws of organic evolution, in general, from the principles brought into view by a similarly narrow cross-section of the evolutionary process. It was the operation of the evolutionary process in adapting the ascendant interests of the individual or the species to current environment that principally occupied attention.

Could this, however, include the method of the whole process? For instance, effective adaptation to existing environment might itself vary. It might, for instance, be adaptation to existing environment so complete that, as must have happened continually in case of extinct forms, it did not offer a sufficiently wide basis for change or development as the conditions of competition altered in the future. Or it might be, as between rival forms, adaptation to current environment which, while rendering the competitors equally efficient in the present, would also include qualities useless and even burdensome in relation to current environment, but contributing, though in varying degrees, to higher efficiency in the future. The evolutionary process would in time, as the future became the present, discriminate between these forms. Higher efficiency in the future would, of necessity, always include adaptation in the present, but the converse would not follow. With progress in the efficiency of life the evolutionary process would tend to become increasingly organic, so that it would be in the development of functions of life such as those associated with the production and organization of variation, the increasing equipment of offspring, and the propagation in numbers in excess of environment—in the operation of which the present was subordinate to the future—that it would tend to produce the most weighty results. Progress from lower to higher types would, in short, necessarily follow the line of variations in which present efficiency included more than adaptation to current environment. It would take place through forms which would bear the burthen of qualities contributing to higher efficiency in the future *in addition* to those concerned in adaptation to current environments.

The condition in which such a result could not be conceived as arising would, of course, be that in which it would have to be accepted that no qualities could exist in life except such as were related, or had been related by the principle of utility to current environment. This would be the case if the Lamarckian hypothesis were correct, and all development in life had to be conceived as the result of inherited effects of use or disuse of organs in direct response to environment. It would also be the case if the action of the Darwinian principle of natural selection had to be conceived as so stringent that no other qualities could co-exist with those related by the principle of utility to current environment.

Following the criticisms to which the Darwinian hypothesis in its return influence on the theory of society became subjected after Darwin's death, it may be observed, accordingly, to have centred in large degree round controversies related to these two leading matters. Darwin had retained to the end of his life a partial belief in the Lamarckian conception of evolution in the forms of life, as due to the transmission to descendants of the effects of use and disuse of organs in the individual (transmission of acquired qualities). "I am convinced," he said, "that natural selection has been the most important, but not the exclusive, means of modification." If the Lamarckian view were accepted as correct, it would, of course, confine the theory of development to the narrowest possible theory of Utilitarianism in relation to current environment. For all qualities would have to be ruled out of life except those produced in ancestors by past environment, plus those which environment might be producing in existing individuals. A central subject of dispute in the Weismann controversies has, however, been the sustained challenge, as regards the higher forms of life, of the doctrine of the transmission of acquired qualities (see HEREDITY), even to the limited extent that Darwin recognized it, accompanied by a considerable extension of the conception of the method in which the principle of natural selection operates in life.

Post-Darwinian developments.

The other controversy has centred round the view that the operation of natural selection tended to be so direct as to rule out, with great stringency, all qualities save those connected by the principle of utility with current environment. Mr Wallace has been one of the most consistent supporters of this view. But it has been challenged in turn by many observers, and the strong case against it is effectively

set out by Romanes (although without continuous insight into the significance of the principle for which he was contending), in his review of the post-Darwinian position in the second volume of *Darwin and after Darwin.*

As the doctrine of evolution now came to be applied more directly to human society, the effect of these positions became visible, and developments followed in rapid succession. Darwin had attempted no comprehensive or systematic study of human society. But in a few of the chapters of the *Descent of Man* he had discussed the qualities of the human mind, including the social and moral feelings, from the point of view of the doctrine of natural selection enunciated in the *Origin of Species.* The standpoint he took up was, as might be expected, practically that of the Utilitarian writers of the period on social subjects, from whom he quoted freely in support of his views. A certain note of hesitation and contradiction is, however, already to be distinguished in this return attempt to fit the facts of human society into the theory of natural selection as it had so far been developed. Thus at times Darwin appeared to think that natural selection could effect but comparatively little in advanced society. "With highly civilized nations," he says, "continued progress depends to a subordinate degree on natural selection." While he noted the obvious usefulness of the social and moral qualities in many cases, he at the same time felt constrained to remark upon their influence in others in arresting, as appeared to him, the action of natural selection in civilization. "We civilized men," he continues, "do our utmost to check the process of elimination (of the weak in body and mind); we build asylums for the imbeciles, the maimed, and the sick; we institute poor laws; and our medical men exert their utmost skill to save the life of every one to the last moment." The attempt is missing to connect the phenomena here brought into view with some wider principle of the evolutionary process which evidently must control them. This aspect of uncertainty is to be noticed in many statements. "It is impossible," he says again, "not to regret bitterly, but whether wisely is another question, the rate at which man tends to increase." In these and similar passages Darwin's attitude of mind is noticeable. An instinctive searching after a higher organic principle in relation to natural selection in society than is to be got out of the current Utilitarian doctrine may be said to be distinguishable.

The position was, however, undergoing rapid development. In the year 1889 Mr Wallace, in a statement of his conception of the doctrine of evolution in his book, *Darwinism,* brought more clearly into view the fundamental difficulty of the early Darwinian conception of natural selection as it began to be applied to society. In the last chapter of the book Mr Wallace maintained that there were in "man's intellectual and moral nature . . . certain definite portions . . . which could not have been developed by variation and natural selection alone." Certain faculties, amongst which he classed the mathematical, artistic, and metaphysical, the latter covering qualities with which he considered priests and philosophers to be concerned, were, he asserted, "altogether removed from utility in the struggle for life," and were, therefore, he thought, "wholly unexplained by the theory of natural selection." He, accordingly, proposed to consider man, in respect of these portions of his mind, as under the influence of some cause or causes wholly distinct from those which had shaped the development of life in its other characteristics.

Wallace's position.

The weakness of this position was immediately apparent. To remove man as regards qualities so directly associated with his social evolution from the influence of the law of natural selection was felt to be a step backwards. It is no injustice to Mr Wallace to say that the effect produced on the minds of the younger school of evolutionists was not so much to convince them that he was right, as to make them feel that the theory of natural selection which he had endeavoured to apply to human society was still in some radical respect incomplete. Mr Wallace's view was severely criticized in many quarters; but it followed, it may be pointed out, by strict logical necessity from his position, already mentioned, as to the supposed stringency of the action of the principle of natural selection in relation to current environment.

A tendency to arrive at a similar crux to that which Mr Wallace here encountered was also to be distinguished in the views of other of the early Darwinians. Huxley had been one of the first converts to a belief in the Darwinian conception of the principle of natural selection. But in the Romanes

lecture delivered in 1893 he had reached a position with regard to the operation of natural selection in human society logically little different from that in which Wallace found himself. In this lecture Huxley actually proceeded to place the ethical process in human society in opposition to the cosmic process, to which latter he considered the struggle for existence and the principle of natural selection belonged. "Social progress," he went on to say, "means a checking of the cosmic process at every step and the substitution for it of another, which may be called the ethical process; the end of which is not the survival of those who may happen to be the fittest, in respect of the whole of the conditions which obtain, but of those who are ethically the best." It was a fallacy, therefore, he thought, to consider "that because, on the whole, animals and plants have advanced in perfection of organization by means of the struggle for existence and the consequent 'survival of the fittest'; therefore men in society, men as ethical beings, must look to the same process to help them towards perfection." The weakness of such a position was scarcely less apparent than in the case of Mr Wallace. Here, also, the fact really in evidence was that the conception of natural selection that had been applied to society was, in some fundamental sense, insufficient.

Huxley's exclusion of the ethical from the cosmic process.

Many symptoms of a change in the conception of the conditions in which natural selection operated in human society were, however, becoming visible. It was evident that society must be organic in some wider sense than had hitherto been generally conceived, or than was possible in the "social organism" which Mr Spencer and the Utilitarians had imagined as centred round the ascendant interests in the struggle for existence of those comprising the political State. Regarding human development in history it did not seem in accordance with evident facts to imply that society was nothing more than political. Social progress was, as a rule, presented in history in association with great types or systems of social order organically related to certain conceptions and beliefs which had subordinated individual conduct and influenced political development over prolonged periods of time. At the present day the great majority of the race was included in a few great systems of the kind, and the fundamental ideas associated with these had influenced in every detail the moral conceptions, habits of life, standards of conduct, and all the principles of politics and of social development of the included peoples for hundreds and, in some cases, for thousands of years. Natural selection, in virtue of the result, was evidently discriminating between these systems, and, therefore, between the peoples which they included. It would probably continue to do so to an increasing degree in the future. Even amongst the most advanced peoples of the present day it was evident that the principles through which political forces were expressing themselves were not really, in the ultimate analysis, principles of the State or of the ascendant interests of those comprised within its consciousness. Western civilization, as a whole, was evidently organic in some wider sense than the life of any of the states included in it. In one sense, and in relation to developments which had influenced it most, it was to be considered as intimately associated with the life-history of a particular form of religious belief. Were, therefore, beliefs of this kind to be studied in respect of their organic relations to the struggle for existence? Were they after all characteristic phenomena of what must be the central function of the evolutionary process in its higher phases—the subordination, necessarily in terms of his own mind, of a reasoning creature to the meaning of an organic process in society, the principles of which extended far beyond the content not only of his individual, but of his political interests?

Developing views concerning the organic nature of human society.

The great difficulties referred to at the beginning as latent in the attempt to apply the doctrine of evolution to society were, however, now in evidence. The position of these beliefs, and the inflamed controversies through which they had come in developments which had taken place in the past had left an atmosphere little favourable at first to the work waiting to be done. Even the attitude of many claiming to represent the scientific spirit was often far removed from that which such a work required, as may often be observed in Huxley's polemical writings. The situation was in many respects unique in the history of thought, and the stage at which the old position begins to be influenced by a new concept is one of much interest.

The conditions in which the two tendencies meet, and the remarkable and conflicting ideas to which they give rise at first, are well exemplified in a passage in one of Mr Karl Pearson's free-thought essays

on the subject of Buddhism published in 1888. Writing as an opponent of religious predispositions, Mr Pearson, nevertheless, felt constrained to ask himself whether a social group possessing such a predisposition might not in the rivalry of existence be thereby placed in a position of advantage with regard to other groups having a less definite religion or no religion at all. "A predisposition, or prejudice having absolutely no rational basis, may," he continued, "have a social value and tend to preserve an individual or group of individuals in the struggle for existence. Do not we here catch a glimpse of how a nigh universal predisposition may exist without our being able to give it a rational basis? We can perhaps trace its historical growth, we may see how it took root, and the mode in which it has developed; but the utmost we can assert is, that its origin and permanence are due to the assistance it gives the human race in the struggle for life. What is true of such predispositions, and the resulting prejudices or beliefs in the mind of mankind as a whole, applies equally well to the customary beliefs of smaller sections of human society. Such beliefs may have absolutely no rational basis, may indeed be demonstrably false, but the race, the tribe, the society may in the long-run force them upon all or the majority of its members,—those who do not accept the belief being destroyed, expelled, or ostracized. The deeper knowledge, the clearer insight may show the individual that many beliefs are due only to racial predispositions; that they are intellectually false and productive of pain and misery to the individual. *He* may go so far as to renounce for himself all the Buddhist delusions, but can such renunciation become a general rule? May not the non-renouncing sections of humanity ultimately survive?"

The inquiry could not, of course, remain in this stage, though Mr Pearson carried it no farther, the position of antagonism from which he set out doubtless closing his mind to the application of the revolutionary concept which had here come into view. As the subject continued, however, to present itself in its wider bearings, it was evident that a very considerable and far-reaching change was at hand. The progress of knowledge had destroyed the self-centred Ptolemaic conception of a universe constructed to revolve round the world on which the observer stood, and to centre in himself. The doctrine of evolution was now, to all appearance, destined to accomplish a scarcely less significant, although in many respects an unexpected, transformation in its application to the science of society. Hitherto in all conceptions of the kind set forth in the passages quoted from Mr Spencer, it will be seen that the science of human development had been made to centre in the ascendant interests of those comprised within the consciousness of the political State. In most of the literature of the French Revolution, in the characteristic principles of the Utilitarian school of philosophy in England, as in the ideas of those phases of continental socialism in which the economic factor is regarded as the ruling factor in history, this conception of society had been fundamental. It may be said to have been in the ascendant during the 19th century. It was evident, however, that its intellectual basis had been undermined, and that the principles controlling the evolution of society must be considered from the standpoint of a much wider outlook.

Widening of the social conception.

The movement of the period in which we are living may, accordingly, be said to be towards what may be called a phenomenology of human evolution in its more organic relations. If the evolutionary process is to be considered as acting on man, through conceptions by which his individual and even political interests are subordinated over long periods of time to the principles of a larger process of life, there can be no doubt as to the direction that social development must take under the influence of natural selection. It must be the social systems which are founded on conceptions rendering society in the highest sense organic, that is to say, social systems which, while of necessity always remaining efficient in competition with other societies in the present, will most effectively subordinate current interests to a higher efficiency in the future, that will be naturally selected.

Looking at the civilization of our current Western era in this light, many of its salient features are seen to present themselves as those of a process of organic development extending over a long period of time, and proceeding in the last analysis from fundamental conceptions of the system of belief associated with it. In the earliest stages of human society the increased efficiency of co-operation over individual effort would be the first principle of development compelling under the influence of natural selection towards social organization. In a further stage in which the

Stages of social development.

efficiency of the social aggregate was centred round the personality of a great leader or military chief, its organic potentiality would be still higher, but liable to be resolved into its component elements on his death. As society grew still more organic and natural selection continued, society under the influence of ideas permanently subordinating the individual to military efficiency would have a great advantage over all others. Great social systems founded on the conception of exclusive citizenship having a religious significance regarded as proceeding from blood relationship to deified ancestors (Ancestor-Worship) would in this stage contain the germs of the highest military potentiality

Where, however, as throughout all this stage of social development, the highest law was always in the last resort a rule of force, and where, therefore, as in the civilizations of the ancient world, the subordination of the individual to the life of the State would be the inclusive ideal of all human effort, the full limits of the organic principle in society would in time be reached. The ultimate ideal of the State itself must, in such circumstances, be universal military conquest, and all social institutions would tend to become, as in the case of slavery, closed absolutisms organized round the conception of the ascendancy of men's desires in relation to the present.

In the next stage, therefore, the enormously higher organic potentiality of a type of society which, while preserving in competition with lower forms its defensive military efficiency in the present, would be influenced by conceptions that would project the sense of human responsibility outside the State and beyond the present, would be evident. In many of the religions of the East such conceptions were to be found in various stages of development. But no Eastern people has, down to the present time, been able to provide for them the permanent military *milieu* in history in which alone their potentiality in the evolutionary process could be realized. The significance, therefore, of the culmination of the military epoch in the ancient classic civilizations of the Western world which preceded the opening of the era in which we are living, and of the fact that the peoples of the same descent who were destined to carry on the civilization of the existing era represent the supreme military stock by natural selection not only of the entire world, but of the evolutionary process itself in human history, will be evident.

With the spread, accordingly, amongst peoples of this origin, and in such a *milieu* in history, of a new conviction of responsibility to principles extending beyond the consciousness of the political State, there would begin a further and more organic stage of the evolutionary process in society. The gradual dissolution in the era in which we are living of all the closed absolutisms within the State, in which human action and ideas had hitherto been confined, is apparently the characteristic phenomenon of this stage. Progress is towards such a free and tolerant, but intense and efficient conflict of forces as was not possible in the world before. It is, it would appear, in this light that we must regard the slow dissolution of the basis of ideas upon which slavery rested; the disintegration of the conceptions which supported the absolute position of the occupying classes in the State; the undermining of the ideas by which opinion was supported by the civil power of the State in the religious struggles of the Middle Ages; the growth of the conception that no power or opinion in the State can be considered as the representative of absolute truth; the consequent development of party government amongst the advanced peoples, with the acknowledgment of the right of every department of inquiry to carry results up to that utmost limit at which they are controlled only by the results obtained in other departments of activity with equal freedom; the growth of the conception, otherwise absurd, of the native equality of men; the resulting claim, otherwise similarly indefensible, of men to equal voting power irrespective of status or possessions in the State, which has been behind the movement towards political enfranchisement; and, finally, the development of that conviction which is behind the existing challenge to all absolute tendencies in economic conditions in the modern world—namely, that the distribution of wealth in a well-ordered State should aim at realizing political justice. These are all features, as the present writer has endeavoured to show (*Principles of Western Civilization*; see also the article in these volumes on SOCIOLOGY), of a developing process in modern history. They must be considered as all related to a controlling principle which has rendered the evolutionary process in society more organic than in any past stage—namely, the projection of the sense of human responsibility outside the limits of the creeds and interests which had in previous stages embodied it in the State.

The increasing intensity and efficiency of the social process amongst the included Western peoples has now, as current history shows, begun, under the influence of natural selection, to tell to an increasing degree in competition with other types of society It must be noticed, however, how the characteristic principle of the process from the beginning has been its projected efficiency. The peoples included in it have had to maintain themselves at every point in competition with other societies of lower future potentiality (as in the struggle extending over many centuries with Mahommedan civilization) by military efficiency. All the qualities to which future potentiality was related were not only useless for centuries of time, but, as in the conditions of the evolutionary process already referred to, they formed a burden that had to be borne in addition to efficiency in relation to current environment.

The characteristic principle of the process.

Here once more the suggestiveness of a study of human society in bringing into view the general principles of the evolutionary process in life has to be noted. The law of progress in life cannot, it would appear, be stated, as was imagined by the early Darwinians, simply in terms of qualities connected by utility with current environment. In human society the operation of the qualities which lead the advanced peoples to build hospitals and asylums for their weaker members carries us beyond that Utilitarianism in the present in connexion with which Darwin discussed it. It is, we see, controlled by that higher organic principle of responsibility to life, extending beyond the meaning of the State, with which the virility and superior efficiency of our civilization is identified, and through which natural selection in the end produces higher results, and on a far larger scale. Similarly, the conception of Mr Wallace that such faculties as those which include the qualities with which he saw priests and philosophers to be concerned could not be accounted for by the operation of natural selection, is seen to be incomplete. It proceeds naturally from Mr Wallace's position, already mentioned, as to the supposed stringency of the action of natural selection in relation to current environment. The qualities which cannot, on investigation, be connected by the principle of utility with existing environment are those correlated with the principle of projected efficiency, as the evolutionary process in society grows more and more organic, and the individual over long periods of time is subordinated to a process, the principles of which extend far beyond the content, not only of his individual, but of his political interests. So far, however, from such qualities having no relation to the principle of natural selection, they are, it will be seen, rather those through which natural selection is producing its largest and most efficient results in human society.

Utility in current environment insufficient; a higher controlling principle present.

Similarly, Huxley's conception that the ethical process in human society was to be placed in opposition to the cosmic process, and was to be regarded as tending to check the struggle for existence and the operation of natural selection must, it would seem, be taken to belong to that earlier stage of the application of the doctrine of evolution when the full reach of the process was not perceived, and when all qualities tended to be viewed in their relation to current environment. So far from it being possible to regard the ethical process as in opposition to the cosmic process, it must, it would appear, be taken that the ethical process *is* the cosmic process, and that it is through the principles and mechanism of the ethical process that the struggle for existence and natural selection are producing, on the largest scale, and in the most effective manner, their most characteristic results in the development of life.

The ethical process identical with the cosmic process.

The changes which the doctrine of evolution is thus beginning to effect in its applications to sociological theory are to all appearance only in their initial stages. In psychology and ethics they can hardly fail to be as important as they already promise to be in the domain of political philosophy. The survival in social and political philosophy of the Ptolemaic standpoint, as represented in the tendency to conceive the principles of the evolutionary process in society as centred in the ascendant interests in the struggle for existence of those comprised within the consciousness of the political State, has still its correlative in psychology and ethics. For instance, it has been hitherto impossible to fit into any theory of empirical psychology certain qualities which Kant found in the human mind. But the basis in the evolutionary process of many of the qualities

The tendencies of current development.

with which Kant was concerned, and which could not be accounted for in relation to experience, just as they could not be accounted for by Mr Wallace in relation to current environment, is now evident. For when the evolutionary process is considered in the wider and more organic relations that have here been discussed, it is clear that the peoples who represent the advanced sections of the race at the present day do so in virtue of qualities in the minds of those who preceded them which had no relationship to current environment. The peoples amongst them who are destined to inherit the future will similarly do so in virtue of qualities which have no Utilitarian relationship to existing environment. In the statement of the principles of the human mind the tendency hitherto in all empirical systems has necessarily been to endeavour to construct a theory of human society and of human progress from an introspective examination of the interests and emotions of the individual mind. But this tendency can hardly fail to be reversed with the continued application of the doctrine of evolution to society. It is the principles of the evolutionary process in society considered in its more organic aspects that must now be considered to be the controlling factor; and it is therefore to be expected that it will be from this wider standpoint that the study of the content of the individual mind itself will in future be approached.

ENCYCLOPÆDIA BRITANNICA.

(SUPPLEMENT.)

Glarus, one of the Swiss cantons, ranking officially as the seventh in order. It has a total area of 267 square miles. Of this 173 square miles are reckoned "productive," forests covering 41 square miles, vineyards but ·07, and land, arable or pasture, 132 square miles. Of the "unproductive" portion 13·9 square miles are occupied by glaciers. A fine carriage road over the Klausen Pass (to Uri) was opened in August 1899, while one is projected over the Praegel Pass (to Schwyz), now crossed by a good mule path. The slate quarries above Elm, at the head of the Sernf valley, were the scene of a great landslip in 1881, when 115 lives were lost. In 1896 there were in the canton of Glarus 10,906 cattle, 3971 pigs, 1237 sheep, and 7037 goats. The mountain pastures number eighty-seven, and are of an estimated capital value of about £250,000. The cotton industry is concentrated in the villages near the chief town. There are eighty factories, employing 10,000 persons, or 55 per cent. of the population. The canton is divided into twenty-eight communes, of which the most populous in 1900 (after the town of Glarus) were Ennenda (2473), Näfels (2527), Schwanden (2400), Netstal (1987), and Linthal (1896). The population of the canton was 33,825 in 1888, and in 1900 it was 32,349. Glarus is one of the few Swiss cantons in which the population is steadily diminishing. In 1899 there were 125 inhabitants per square mile. The canton is mainly Protestant (in 1900 there were only 8006 Roman Catholics) and German-speaking (in 1900, 370 Italians represented the largest non-German tongue in the canton). Glarus still preserves its primitive democratic assembly of all men over twenty years of age. The communes (forming eighteen electoral circles) elect for three years a sort of "standing committee" (*Landrath*), in the proportion of one member for every 500 inhabitants or fraction over 250, but the Landsgemeinde itself names for three years an executive of five members. Owing to the pure democracy in Glarus, no referendum, &c., is required, as that is exercised annually at the meeting of the Landsgemeinde. The present cantonal constitution dates from 1887. In 1897 the state revenue of Glarus was 1,056,959 francs (a rise of 56¼ per cent. since 1885), while the state expenditure was 1,026,375 francs (a rise of 48¼ per cent. since 1885). In 1897 the public debt was 4,210,500 francs. GLARUS, the capital of the canton, is 1578 feet above the sea-level. It is a clean, modern little town, with wide streets. Population (1888), 5357, of whom 1502 were Roman Catholics and only 100 non-German-speaking; (1900), 4896.

See BABLER. *Die Alpwirthschaft im Kant. Glarus.* Soleure, 1898.—HEER. *Geschichte d. Landes Glarus,* 2 vols. Glarus, 1898–99. (W. A. B. C.)

Glasgow, a royal burgh, city, and county of a city (1893), Scotland, on both banks of the river Clyde, 401½ miles north-west by north of London by rail, and 47½ west by south of Edinburgh.

Area and Population.—Under the Local Government Act (Scotland), 1889, the city was placed wholly in the county of Lanark. In 1891 the municipal boundary was extended to include six suburban burghs and a number of suburban districts, the area being increased from 6111 acres to 11,861 acres. The total area of the city and the coterminous burghs of Govan, Partick, and Kinning Park, which resisted annexation in 1891, is 15,659 acres. In 1893 the municipal burgh was constituted a county of a city. The population was in 1881, 511,415; 1891, prior to extension of boundary, 565,839; after extension, 658,198; 1901, 760,423, the increase since 1891 being nearly 16 per cent., compared with 14 in 1881–91. The birth-rate, 1896–98, was 33·6, against 33·9 in 1891–95, and 35·5 in 1886–90; in 1899 it was 33·0. The marriage-rate during the years 1896–98 was 9·7; in 1899 it was 10·2. Mainly through the vigorous administration of the Public Health Committee of the Corporation the death-rate has been reduced from 30 to 33, at which it stood less than half a century ago, to 21·6 in 1899. Of the population in 1891 the number of Gaelic-speaking persons was 17,925; 211,477 were natives of other parts of Scotland, 349,597 of the city itself, and 66,071 of

Ireland. Professional persons numbered 9540 men and 3937 women; commerce engaged the attention of 39,983 men and 3825 women; industry of 130,150 men and 60,230 women, of whom 15,275 men were concerned with machines and implements, 1898 men with ships, 9452 men and 19,979 women with textiles, and 29,964 men and 1695 women with minerals. Valuation of the city in 1878–79, £3,420,697; in 1899-1900, £4,780,000.

Constitution and Government.—Since 1885 the city has been divided for the purpose of representation in Parliament into seven divisions, each of which returns a member. Under the local Act of 1891 the corporation was increased from 50 to 77 members, with 15 magistrates, including the Lord Provost; and under the local Act of 1895 all the powers which the Town Council exercised as Police Commissioners, and trustees for parks, markets, water, &c., were consolidated and conferred upon the corporation as such. In 1898 the two parish councils of the city and barony, which administered the poor law over the greater part of the city north of the Clyde, were amalgamated as the Parish Council of Glasgow, with 31 members. As a county of a city Glasgow has a lieutenancy —successive Lord Provosts having hitherto been appointed Lords-Lieutenant—and a Court of Quarter Sessions, which is the appeal court from the magistrates as licensing authority.

The municipal government of Glasgow is notable for its efficiency in most departments, and the corporation has led the way in several enlargements of the municipal function. New City Chambers in George Square, Venetian in character, which cost about £600,000, were opened in 1889; and since then several additional blocks of buildings have had to be built, acquired, or leased, to house an ever-increasing staff of officials. Admirably equipped sanitary chambers were opened in 1897; they embrace a bacteriological and chemical laboratory. The first part of a scheme for intercepting and purifying the sewage of the city was completed in 1894. Powers were obtained in 1896 and 1898 to treat in the same way the whole sewage emptied into the Clyde and Kelvin by Glasgow, suburban burghs, and adjoining county districts, and it is certain that the estimated cost of £1,100,000 will be largely exceeded before the work is completed. Under an Act of 1895, Loch Katrine, from which the city draws most of its water, was raised 5 feet, and Loch Arklet, with a storage of 2,050,000,000 gallons, connected with it by tunnel; the two lochs together will ultimately have a capacity of about 12,000,000,000 gallons. The entire works between the loch and the city have been duplicated over a length of 23½ miles, and an additional reservoir, holding 694,000,000 gallons, has been built, adding 18 to the previous 12½ days' supply which is held in reserve. Hydraulic power has been supplied to manufacturers and others by the Water Committee since 1895. In 1899 the corporation had under its control five gasworks, with a productive capacity of 35,215,000 cubic feet of gas per day, which is sold to about 200,000 subscribers in and around the city at 2s. 6d. per thousand feet; and additional works, now being built at a cost of £1,000,000, will add 40,000,000 cubic feet to the daily output. The corporation began to supply electric light in 1893; 75 miles of distributing mains have been laid, and 2,824,350 units were sold to 2000 consumers in 1899. Part of the city is lit by electricity at a charge of £14 per lamp, and two large generating stations are at work, and a third is being built. But the greatest enterprise undertaken by the corporation in recent years is the working of the city tramways. Since the expiry of the lease of the company which used the lines up till 1894 the number of passengers carried has been more than doubled, and the revenue of the tramways department has reached nearly half a million sterling a year. Overhead electric traction is employed. The corporation acquired St Andrew's Halls in 1890, and has since purchased or built six public halls in different parts of the city, and contemplates the erection of more. A new infectious diseases hospital at Ruchill, consisting of 33 blocks of buildings, to accommodate 408 patients, was completed in 1900, supplementing the accommodation for 390 which already existed at Belvedere. Vast additions have been made to the parks and open spaces of Glasgow in recent years. Queen's Park was enlarged in 1894 by the enclosure of the grounds of Camphill (58 acres). The Cathkin Braes (49 acres) was presented in 1886, Bellahouston (176) was purchased in 1895, Ruchill (53) in 1891, Tollcross (82¾) in 1897, Springburn (53¼) in 1892, Richmond Park (44) in 1898, and Maxwell Park became the property of the corporation on the annexation of Pollokshields in 1891. The Botanic Gardens also became public property in 1891, and with subsequent additions now form a combined scientific institution and a public park of 40 acres. In addition there is a large number of open spaces, of which 11, covering a total area of 33,614 square yards, have been acquired since 1889.

A People's Palace, combining a conservatory and art gallery and museum, was erected on Glasgow Green in 1898, and a winter garden is being built in Springburn Park. New corporation art galleries have been erected in Kelvingrove Park at an estimated cost of £200,000, a considerable proportion of which was derived from the profits of the Exhibition held in 1887. Glasgow Bridge was rebuilt and widened in 1899 at a cost of £100,000. Rutherglen Bridge was rebuilt in 1896, and Dalmarnock Bridge in 1891. A new central station has been erected for the fire brigade, which has nine stations in the city and one sub-station. And a telephone exchange has been opened by the corporation under the Telegraphs Act of 1899.

Streets and Buildings.—Thirty-eight miles of new streets have been laid out since 1880. In the same period authority has been given for the erection of buildings of all kinds costing nearly £18,000,000, of which £6,000,000 were authorized to be spent in the three years 1896–99. The Improvements Act of 1866 was amended by an Act of 1881. Under it the Improvement Trustees (corporation) began in 1888 to build houses for the poor—sanitary dwellings at a rent of £4, 10s. for single-roomed houses and upwards. Then they began to erect lodging-houses for men and women, and ultimately became the owners of seven such houses, to which was added in 1896 a family home for the accommodation of whole families in certain circumstances. When the powers of the trust were practically exhausted in 1896 it was found that £1,955,550 had been spent in the 29 years in the purchase and improvement of land and buildings, and £231,500 in the erection of tenements and lodging-houses—total, £2,187,050; and on the other hand, ground had been sold for £1,072,000, and the trust owned heritable property valued at £692,000, showing a deficiency of £423,050. The assessment of the ratepayers for the purposes of the trust had brought in £593,000 in all, and it was estimated that the operations, beneficial to the city in a hundred ways, had cost the citizens about £24,000 a year for 29 years. Under a new Improvements Act obtained in 1897, £560,000 is at present being spent in dealing with other insanitary and congested areas in the centre of the city and on the south side of the river, and in acquiring not more than 25 acres of land, within or without the city, for the erection of dwellings for the poorest classes.

In 1891 the Mitchell Library was rehoused in Miller Street in a building formerly occupied by the Water Commissioners. The new post office was commenced in 1876 and completed in its present form in 1896, and already it has been found necessary to erect a new parcels department in another part of the city. Other public buildings dating since 1880 are the Inland Revenue Office (1885), Corn Exchange (partially rebuilt 1896), Athenæum (1888 and 1893), Theatre Royal (partially after fire in 1895), Y.M.C.A. Club (1897), and Bible Training Institute (1898), both pendicles of the Christian Institute (1879); Victoria Infirmary (1890), Fine Art Institute (1880), two wings of the High School (1887 and 1897), 69 public schools (since 1873), new School of Art (1899), Sick Children's Hospital (1882–87), Anderson's College Medical School (1887), Conservative Club (1894), Queen Street Station (1880), and a number of district railway stations. Gartloch Asylum was opened by the City Lunacy Board in 1896 in Cadder parish. The Central and St Enoch's stations are being enlarged, and the Royal Infirmary is about to be reconstructed at a cost of £100,000 as a memorial of Queen Victoria's Diamond Jubilee. Langside Battlefield Memorial was erected in 1887, and a Gladstone statue is to adorn George Square. Street architecture has greatly improved in Glasgow, but recently a strong tendency has been manifested to pile up gigantic business premises.

Communications.—The City and District Railway (circular), belonging to the North British Company, was opened in 1886. Cathcart District Railway (Caledonian) was completed in 1886, and made circular for the south side of the city and suburbs in 1894. In 1896 the Caledonian Railway Company opened the whole extent of a 6½-miles railway, which runs, underground for the most part, through the heart of the city from Maryhill to Dalmarnock. This (central) railway has two junctions in the city with the Lanarkshire and Dumbartonshire Railway, opened in the same year, and at the other extremity it throws off a branch to Tollcross, opened in 1897. Both the Caledonian and Glasgow and South-Western Companies are at present doubling the roads entering their principal stations. The Glasgow Subway—an underground cable passenger line, 6½ miles long, worked in two tunnels and crossing beneath the Clyde twice—was opened in 1896. For tramways, see above. Communication up and down and across the river is provided by small steamers run by the Clyde Trust, which carried 12,000,000 passengers in 1899; and it is now proposed to make cross-transit free in default of the provision of bridges across the harbour, which would hamper the shipping. There are two steam ferry boats or floating bridges for vehicular traffic, and there is a subway for foot and wheeled traffic at Stobcross.

Harbour.—Queen's Dock at Stobcross was completed in 1880. Prince's Dock, on the south side of the river, was opened in 1897. It is 72 acres in extent, divided into three basins and a canting basin; the quayage is 2⅛ miles long, and the entrance 156 feet wide. It is 20–28 feet deep at low water and 31–39 feet at high water, and is fully equipped with hydraulic and steam cranes, one of which lifts 130 tons. A second graving dock was opened in 1886, and a third in 1897. The three are respectively 551, 575, and 880 feet long, and the third has a width of 83 feet, and can be made at will into two docks of 417 and 457 feet long. The total area of the harbour is now 206 acres, and the length of the quays and wharves is more than 8¼ miles. The accommodation for mineral traffic has been increased by 64 per cent. since 1884, and the storage and quayage for timber was doubled in 1896. A new mineral dock is to be built by the Clyde Trust at Clydebank. Continuous work had been done at the deepening of the river. The dredging plant now owned by the Trust lifts two million cubic yards of material in the year, double the quantity lifted in 1884, and between 1885 and 1900 the depth of the channel was increased to a minimum of 22 feet, and vessels drawing 26 feet can go up or down on one tide. The debt of the Trust is nearly 5¾ millions, and the revenue, which was £291,000 in 1884, is now £439,000 a year.

The tonnage registered at the port in 1898 was 1667 vessels of 1,586,743 tons, and the movements of shipping were—1888, entered 9361 vessels of 2,885,672 tons, cleared 9400 of 2,998,835 tons; 1898, entered 11,091 vessels of 3,710,206 tons, cleared 11,476 of 3,964,108 tons. Imports were valued at £10,864,084 in 1888, and £12,788,374 in 1898; exports of the manufactures of the United Kingdom, £14,461,488, and of colonial goods, £523,865 in 1888, and £13,137,275 (United Kingdom) and £462,589 (foreign and colonial) in 1898. The principal article of import is flour, of which £2,158,465 worth was imported in 1898. Animals come next at £978,608; wood imports were valued at £905,190; wheat, £636,270; iron ore, £500,375; fruit, the trade in which has reached large dimensions in recent years, £425,465. The chief exports were in 1898 cotton manufactures, valued at £2,508,112; manufactured iron and steel, £1,797,395; machinery, £1,785,985; spirits, £1,038,320; cotton yarn, £837,226; linen fabrics, £719,060; coal, £576,327; jute yarn and goods, £409,039; woollen manufactures, £219,166. The customs revenue of the port rose from £969,339 in 1880 to £1,748,822 in 1898.

Industries.—There are 11 shipbuilding yards within the harbour of Glasgow, and 40 considerable shipbuilding firms operate in the river and firth. The Clyde output for 1899 was 41 sailing vessels of 14,618 tons, and 243 steamers of 476,456 tons—total tonnage, 491,074; the output in 1898 was 466,832; 1897, 340,037; 1896, 410,841; 1895, 360,152; 1894, 340,885; 1890, 349,995; 1880, 241,114. Marine engines of 478,503 i.h.p. were turned out in 1899; 510,805 in 1898; 373,195 in 1897; 295,620 in 1894. The manufacture of steel armour for battleships is the only industry of importance added to the activities of Glasgow of recent years, and it is probable that the making of ordnance will presently be associated with it. All trades connected with iron and steel have developed; textiles have not, mainly owing to the short supply of female labour. There are in the city 1977 factories and nearly 8000 workshops. There were in 1900 five cotton factories in operation, with a total of 325,000 spindles, and other industries are represented as follows:—Textile factories (including those devoted to cotton and five or six to carpet-weaving), 56; engineers and boilermakers, 186; iron foundries, 58; brass foundries, 60; chemical works, 20; white lead, 2; bichromate of potash, 1; paint and colour works, 30; confectioners, 20; biscuit makers, 9; tobacco factories, 15; clothing factories, 91; printers and bookbinders, 231; boot factories, 17; lace curtain factories, 4; printing and bleaching works, 61; cabinetmaking works, 61; flour-mills, 9; distilleries and breweries, 14; laundries, 19; saw-mills, 65; match-making works, 2; lead-smelting works, 1; indiarubber factories, 2; potteries, 8; aërated water works, 45.

University, Colleges, and Schools.—The university has now 31 professors and 32 lecturers, the latter almost all of recent institution. Queen Margaret College for women, established 1883, with an endowment of upwards of £25,000, was incorporated with the university in 1893, and is used for the teaching of women students, who are to a large extent segregated from the men

students. The foundations, scholarships, &c., of the university amount to about £14,000, and the number of matriculated students in 1898–99 was 1647, of whom 306 were women. A Muirhead College for women is in process of establishment. The Glasgow and West of Scotland Technical College was founded in 1886 by a combination of the non-medical part of Anderson's College, the College of Science and Arts, Allan Glen's Institution, and the Atkinson Institution, and is subsidized by Hutcheson's Trust, the City Educational Endowments Board, and the corporation. Anderson's College Medical School was incorporated in 1887, and St Mungo's College, with faculties of medicine and law, in 1889. There are two educational endowments boards, which apply a revenue of about £10,000 a year to the foundation of bursaries mainly. There are four high schools for boys and two for girls, besides two Roman Catholic academies for boys and one for girls, and the Glasgow School Board has among its schools 11 equipped with secondary departments or as science schools, and the Govan Board 6. Six School Boards—Glasgow, Govan, Maryhill, Springburn, Eastwood, and Cathcart—control the elementary education of Greater Glasgow (including Govan and Partick, with a total population in 1891 of about 780,000); the public schools number 97, and they had an average attendance of 93,968 in 1898–99.

Churches.—There are in Greater Glasgow 86 Established churches, 89 Free, 69 United Presbyterian (these and most of the Free churches now belonging to the United Free Church), 3 Original Secession, 1 Reformed Presbyterian, 2 Free Presbyterian, 26 Congregational Union, 2 Evangelical Union, 14 Baptist, 6 Wesleyan, 2 Swedenborgian, 2 Unitarian, 2 German Protestant congregations, 1 French Protestant, 2 Hebrew, 27 Scottish Episcopal (including missions), 1 English Episcopal, and 21 Roman Catholic. Four orders or congregations of Roman Catholics are represented in Glasgow—Jesuits, Passionists, Franciscans, and Marists—and there are 8 convents or conventual institutions.

(W. WA.)

Glass.—Glass is an amorphous solid substance, formed by the action of heat, and consisting of mixtures of silicates, borates, and phosphates. It may be transparent, translucent, or opaque. Former definitions have been rendered obsolete by recent researches, and the present definition may meet with a similar fate, although a comparison of the analyses of English and foreign staple glasses (soda-lime, potash-lime, and potash-lead glasses) shows that the composition of these glasses is practically constant. The attempts to represent the different varieties of glass as definite chemical compounds have not been attended with success. The knowledge of the chemistry of glass has been considerably widened by the experiments carried out by Dr Schott at the Jena glassworks with reference to the manufacture of new kinds of optical glass. The commercial success and extensive development of these works have demonstrated the value of pure science to manufactures. In spite of the example set by Messrs Chance, who secured the services of M. Bontemps and Dr Hopkinson, and encouraged their researches, there has been no marked scientific development in English glass manufacture in recent years. It is doubtful how far State aid can permanently benefit an industry, but it is certain that no institution for aiding scientific industry exists in England comparable to the Imperial Technical and Physical Institute of Charlottenburg; and Dr Abbe and Dr Schott, the founders of the Jena glassworks, acknowledge their indebtedness to the Prussian Education Bureau and to the Diet for liberal and repeated subsidies, which enabled them to carry out costly investigations on a commercial scale.

In the preparation of the varieties of colourless glass in general use few new materials have been introduced. Sulphate of soda is now universally used for plate and sheet glass, and carbonate of barium has been substituted for red lead in several manufactories of pressed glass.

For rendering the ordinary potash-lead and soda-lime glasses opalescent or opaque, arsenic trioxide, tin oxide, cryolite, and a mixture of felspar and fluor-spar have been employed. (See MOSAIC.)

In preparing coloured glasses the chemical nature of the glasses must be considered. Some of the colour-giving metallic oxides develop one tint when mixed with a soda-lime glass, and a quite different tint when mixed with a potash-lead glass. With the latter the oxide of nickel gives a rich purple colour, with the former a reddish brown. The "charcoal" yellow, which so frequently occurs in the mosaic windows of the 13th century, can only be developed with a soda-lime glass. The yellow colour due to silver oxide can only be obtained by applying it to the surface of glass in the form of a pigment and subjecting the glass to a moderate heat in a kiln.

The use of gas furnaces for *melting glass* has become general. In the new form of Siemens furnace, additional economy of fuel is effected by building the gas producer as part of the furnace, and as the gas regenerators can be omitted the cost of construction is reduced.

In dealing with manufactured glass it will be convenient to adopt the following classification:—

I. Optical Glass. II. Blown Glass. III. Glass pressed or blown mechanically.

Table Glass. Tube. Sheet and Crown Glass.

Coloured Glass for Windows.

Plate Glass. Pressed Glass. Glass blown by compressed air.

I. OPTICAL GLASS.

The story of the manufacture of optical glass closed in the ninth edition of this *Encyclopædia* with the purchase in 1867 by the French Government of a pair of crown and flint discs, 29 inches in diameter, manufactured by Chance Bros. of Birmingham. To understand the subsequent development of the manufacture it is necessary to recall the work of Fraunhofer. Fraunhofer originated the idea of examining the influence exerted by the chemical constituents of glasses on their optical qualities.

Moreover, by his system of spectroscopic examination, he was the first to denote the optical properties of glasses in exact figures—to measure accurately the refractive index and dispersion, and to demonstrate the disproportionate increase of dispersion in crown and flint glass. Following in Fraunhofer's steps, and with the same object, namely, the elimination of the secondary spectrum, the Rev. W. V. Harcourt and G. G. Stokes carried out a prolonged series of experiments in glass-making, and examined the optical qualities of glasses in which phosphoric anhydride took the place of silica. Similar experiments were also conducted by Dr J. Hopkinson. In 1881 Professor Abbe and Dr Schott commenced their researches. The task they set themselves was to study the influence on refractive index and dispersion of every chemical element which could be combined to form an amorphous glass; to these researches, which were at first carried on on the scale of laboratory experiments, the Jena glassworks owe their origin. The example set by Abbe and Schott was closely followed by Messrs Chance of Birmingham and the late M. Mantois of Paris. The problem requiring solution was the removal of the secondary spectrum in combinations of crown and flint glass by the production of crown and flint glass of such quality that when examined spectroscopically the increase of dispersion in the two glasses is proportional in all parts of the spectrum. With reference to this problem, Dr Schott says: "When, in 1881, we began our experiments we had very satisfactory results by using glasses containing borates and phosphates. The great hopes we formed of these were, however, disappointed, in so far as these glasses did not prove durable enough for all purposes, and therefore their manufacture had to be discarded to a certain extent." The following examples show the progress that has been made towards obtaining a perfect combination (the numbers denote the relative partial dispersion in different parts of the spectrum):—

		A′ to D	D to F	F to G
Early combination of Jena glasses	Light Flint	0·615	0·713	0·600
	Hard Crown	0·643	0·703	0·566
Recent combination of Jena glasses	Flint . .	0·635	0·705	0·573
	Crown .	0 644	0·707	0·568

Another problem especially affecting the manufacture of photographic objectives is the production of glasses possessing greater variation between refractive index and medium dispersion, so as to afford a choice of several glasses of the same refraction but of different dispersion. The following are examples. D represents refractive index; G′–D medium dispersion:—

	D	G′–D
Crown glass with high dispersion .	1·5289	0·01374
Baryta Flint glass	1·6235	0·02107
Baryta Crown glass, densest . .	1·6112	0·01363

The following are analyses of some of the more interesting of the Jena glasses:—

	SiO_2	Na_2O	K_2O	Al_2O_3	MgO	PbO	ZnO	BaO	B_2O_3	P_2O_5
Light Baryta Flint .	65·6	1·23	6·47	..	..	1·03	12·2	9·97	3·27	..
Baryta Silicate Crown .	71·4	3·53	7·78	..	..	..	4·50	9·52	3·13	..
Light Phosphate Crown	..	...	14·8	11·3	11·6	...	..	..	4·98	56·6
Borate Flint . . .	..	4·12	..	10·0	..	6·87	12·6	..	66·3	..

At the present time M. Mantois's successor publishes a list of 110 different optical glasses, and the list of the Jena works contains 76. Messrs Chance's list for 1900 is as follows:—

ORDINARY CROWNS AND FLINTS.

Kind of Glass.	Refractive Index for D	Medium Dispersion C–F	$V=\frac{n-1}{\Delta n}$	Partial Dispersion. C–D	D–F	F–G′	Specific Gravity.
Hard Crown . . .	1·5175	0·00856	60·5	0·00252	0·00604	0·00484	2·48
Soft Crown. . .	1·5152	0·00906	56·9	0·00264	0·00642	0·00517	2·55
Extra Light Flint . .	1·5316	0·01085	49·0	0·00313	0·00772	0·00630	2·78
" . .	1·5333	0·01099	48·5	0·00322	0·00777	0·00640	2·80
Light Flint. . . .	1·5472	0·01196	45·8	0·00348	0·00848	0·00707	2·93

M. Mantois, the maker of the 40-inch lenses for the Yerkes telescope, and the 49-inch lenses for the great telescope of the Paris Exhibition of 1900, gives the following description of the manufacture of glass discs for large lenses:—

The aim (he says) of the manufacturer is to produce large blocks of glass absolutely homogeneous and physically clear, entirely free from those transparent threads, cords, and striæ which are almost invariably found in ordinary glass. The furnaces employed are small, being constructed for a single crucible. The crucibles hold from 10 to 18 cwt. of glass, and are similar in shape to those used for flint glass, except that the mouth is elongated so as to project beyond the wall of the furnace. A crucible is built into a furnace, whilst cold, and the only part which remains visible is the projecting mouth. The temperature is raised slowly, and when the furnace is at a bright red heat the first charge of the raw material is shovelled into the crucible through the mouth. Successive charges are gradually added, until the crucible is full. About ten hours after the last charge has been added the furnace is driven to its highest temperature in order to disengage and expel from the glass all bubbles of air and gas. After the so-called "plaining" or refining process has lasted some twenty hours, a specimen of the molten glass is drawn from the crucible and examined with a microscopic lens to see if any bubbles remain. After several specimens have been examined and the molten glass is pronounced to be "plain," the temperature of the furnace is slightly lowered, the stopper and clay are removed from the mouth of the crucible, and the surface of the glass is skimmed to remove all floating impurities. After the glass has been skimmed the "stirring" process is commenced. In molten glass the constituents, silicates, borates, and phosphates have a tendency to separate, and either to sink or rise in the crucible according to their density. To break up the threads, cords, or striæ produced by this separation, to maintain the intimate mixture of the constituents, and to render the mass of the glass perfectly homogeneous, constant and prolonged stirring is absolutely necessary. The stirring apparatus is exceedingly simple. A cylinder of fireclay, closed at one end, which has been raised to a white heat, is gradually lowered into the molten glass. The bent end of a long iron bar is inserted in the mouth of the cylinder, the weight of the bar is supported by a chain, and a long wooden handle is attached to the end of the bar farthest from the furnace. The bar is so poised that a man by moving the handle can direct the cylinder into any part of the crucible, and keep the whole mass of glass in a state of gentle agitation. The work is exceedingly trying, especially during the first few hours, whilst the furnace is almost at its highest temperature. The workmen are dressed in asbestos-cloth, and relieve each other at short intervals. The process requires constant supervision, as different glasses require different manipulation; moreover, if bubbles are formed by the stirring, the work must immediately be stopped, the cylinder removed, the crucible closed, and the heat of the furnace increased. If no bubbles are formed the stirring is continued for from ten to fifteen hours, whilst the temperature of the furnace is allowed steadily to diminish. As the temperature diminishes the glass becomes more viscous, until the clay cylinder can only be moved

with difficulty. As there is no longer any danger of the constituents of the glass separating, and of "cords" being formed, the cylinder is drawn carefully to the mouth of the crucible and removed, and the fire is allowed to die down. After an interval of five or six hours, during which the glass has cooled rapidly, the cooling is checked by hermetically closing the crucible and furnace. This is done to prevent the glass from becoming "case-hardened," like so-called "toughened" glass. The crucible remains untouched for a period, varying from six days to six weeks, according to the size of the discs required and the nature of the glass. When the furnace is opened the crucible is drawn out, and the walls of the crucible are broken away from the glass. (In the manufacture of large lenses a crucible can only be used for one melting.) The mass of glass is usually found to be broken into several irregularly-shaped pieces. Each piece is examined microscopically, and by transmitting through the glass a beam of concentrated light, which shows up every imperfection. In spite of prolonged stirring and every precaution, parts of the glass are invariably found defective. These defects are due partly to irregularity of cooling, the exterior layers of the glass having naturally cooled more rapidly than the interior, and partly to the disturbance caused by the removal of the clay cylinder. It is rare that more than half of the contents of a crucible is perfectly clear and homogeneous. After the examination, the defective parts are chipped away with a hammer, or ground away by a revolving iron disc fed with emery and water. In order to convert the selected pieces, which are often irregular in form, into discs of regular form, each piece is placed in a mould made of fireclay and subjected to heat, sufficient to cause the glass to take the shape of the mould, but insufficient to produce complete fusion. The moulding process must be conducted with the greatest care, as a slight excess of heat may render useless all the labour previously expended. After the glass has taken the form of the mould the fire is allowed to die out, and the kiln in which the process has been conducted is hermetically closed. By the first moulding the irregular fragments of glass are converted into discs with parallel faces; by a second moulding, and by using moulds possessing various degrees of curvature, the discs are caused to assume roughly the form of lenses. Before the last process of moulding, part of the edge or surface of each disc is polished and the glass once more examined for defects.

II. Blown Glass.

Table-Glass and Vases.—The following is the composition of the varieties of glass used:—

	S_1O_2	K_2O	PbO	Na_2O	CaO	MgO	Fe_2O_3 and Al_2O_3
Potash-lead (Flint) glass	53·17	13·88	32·95	..	..	..	..
Soda-lime (Venetian) glass	73·40	..	..	18·58	5·06	..	2·48
Potash-lime (Bohemian) glass	71·6	15·0	..	..	10·0	1·2	2·2

Regenerative gas furnaces are being gradually adopted. In many works, however, the old-fashioned coal or coke furnaces, fitted in some cases with mechanical feeders, are still in use. For potash-lead glass covered crucibles are used, holding from ½ to ¾ ton of molten glass. Open, basin-shaped crucibles are used for leadless glasses. Potash-lead glass, although readily fusible, is so viscous and tenacious of gas and air bubbles, that, with the appliances now in use, the raw materials cannot be converted into clear workable glass in less than from fifty to sixty hours. The distinctive qualities of potash-lead glass are its ductility when heated and its brilliancy and colourlessness when cold. Owing, however, to its brilliancy, it is not so well adapted to display niceties of form as a leadless glass, which may be far from faultless with regard to clearness and colour. All table-glass worthy of the name is blown glass. Every vase, wine-glass, or decanter has commenced its existence in the form of a bubble at the end of a blowing-iron, and owes its form to simple tools guided by delicate touch and trained eyesight. The revival in recent years of the craft of glass-blowing in England must be attributed to William Morris and T. G. Jackson, R.A. They, at any rate, seem to have been the first to grasp the idea that a wine-glass is not merely a bowl, a stem, and a foot, but that, whilst retaining simplicity of form, it may nevertheless possess decorative effect. They, moreover, suggested the introduction for the manufacture of table glass of a material similar in texture to that used by the Venetians, both colourless and tinted (see Plate).

In 1870 the colours available and used for English table-glass were ruby, canary-yellow, emerald-green, dark peacock-green, light peacock-blue, dark purple-blue, and a dark purple. About that year the "Jackson" table-glass was made in a light, dull green glass, similar to that used in stained glass as "white," containing a wealth of bubbles and interesting irregularities. Owing to these so-called defects the glass only appealed to a very select circle. The dull green, commonly known as "pale green," was followed successively by amber, white opal, blue opal, straw opal, sea-green, horn colour, and various pale tints of soda-lime glass, ranging from yellow to blue. Experiments have also been tried with a violet-coloured glass, a violet opal, a transparent black, and with glasses shading from red to blue, red to amber, and blue to green. Touches of colour have been added to vessels in course of manufacture by means of seals of molten glass, applied like sealing-wax; or by causing vessels to wrap themselves round with threads or coils of coloured glass. By the application of a pointed iron hook, while the glass is still ductile, the parallel coils can be distorted into bends, loops, or zigzags (Figs. 3, 4).

The surface of vessels may be rendered lustrous by rolling the hot glass on metallic leaf, or iridescent, by the deposition of metallic tin, or by the corrosion caused by the chemical action of acid fumes. Gilding and enamel decoration are applied to vessels when cold, and fixed by heat. Cutting and engraving are produced by pressing the surface of vessels against the edge of wheels revolving on horizontal spindles. "Cutting" wheels range from 18 inches to 3 inches in diameter, and are made of iron for grinding, stone for smoothing, and wood for polishing. "Engraving" wheels are small, ranging from 1 inch to ¼ inch, and are made of copper. It is the fashion to run down "cutting" as a form of decoration. As, however,

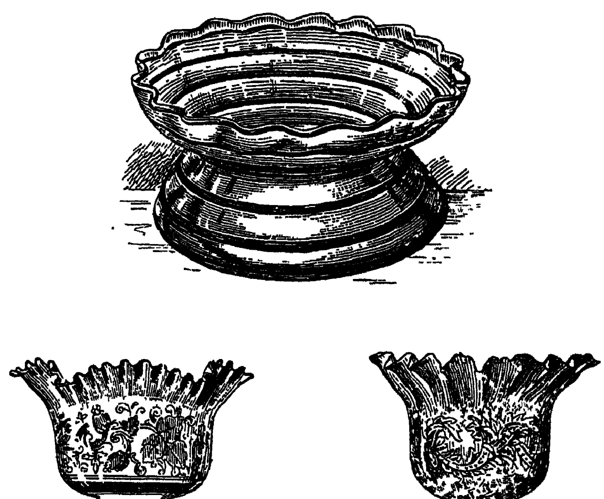

Fig. 1.—Glass mechanically "crimped."

"cutting" brings out one of the intrinsic beauties of potash-lead glass, namely, its remarkable power of reflecting and refracting light, the reason that it is decried must be on the ground of misapplication, rather than unfitness. The fault probably lies in cutting too deeply and too lavishly. When a vessel is smothered with cutting, form disappears in sparkle. The true use of engraving is to add interest to vessels by means of coats-of-arms, monograms, inscriptions, and graceful outlines. The improper, but too common, use of engraving is to hide defective material.

The influence exerted by public taste upon glass-blowing has not always been conducive to the best interests of the craft. Some instances are sufficiently curious to deserve notice. Large numbers of shades for gas, oil, and electric light, as well as bowls for flower-vases, were rendered decorative by allowing the edges of the mouths, while still ductile, to arrange themselves in natural folds. The discriminating public thought these natural folds to be too irregular, and certain manufacturers promptly introduced a machine, closely resembling a guillotine, which crimped the folds with mathematical precision (Fig. 1). This curious distrust of natural irregularity has had the effect of, to a great extent, spoiling opal glass. The beauty of opal glass consists in the wanton irregularity of its shading, no two pieces being precisely similar (Fig. 2). The public asked for regularity, and have been supplied with an insipid milk-and-water material, which is called opal. "Threading" has suffered much in the same way. By the old method of hand-threading the spaces between the threads or coils of coloured glass are always more or less irregular. A lathe has been introduced which not only winds the glass thread with exasperating exactitude, but renders it possible to cover a vessel with threading from top to bottom. Iridescence, when first introduced, was applied delicately to vases of suitable form; it was, however, before long applied to utensils of every description, and the effect, so far from suggesting the actual lightness and brightness of a bubble, is often rather more suggestive of the putrescence of a stagnant pool. Reticence and restraint in decoration have few advocates, and there is a constant demand for any kind of novelty, provided it is highly coloured and exuberantly trimmed. The unfortunate feature of the misuse of processes of decoration is not so much that it offends good taste, but that it brings into disrepute processes which, when properly used, are capable of producing beautiful effects.

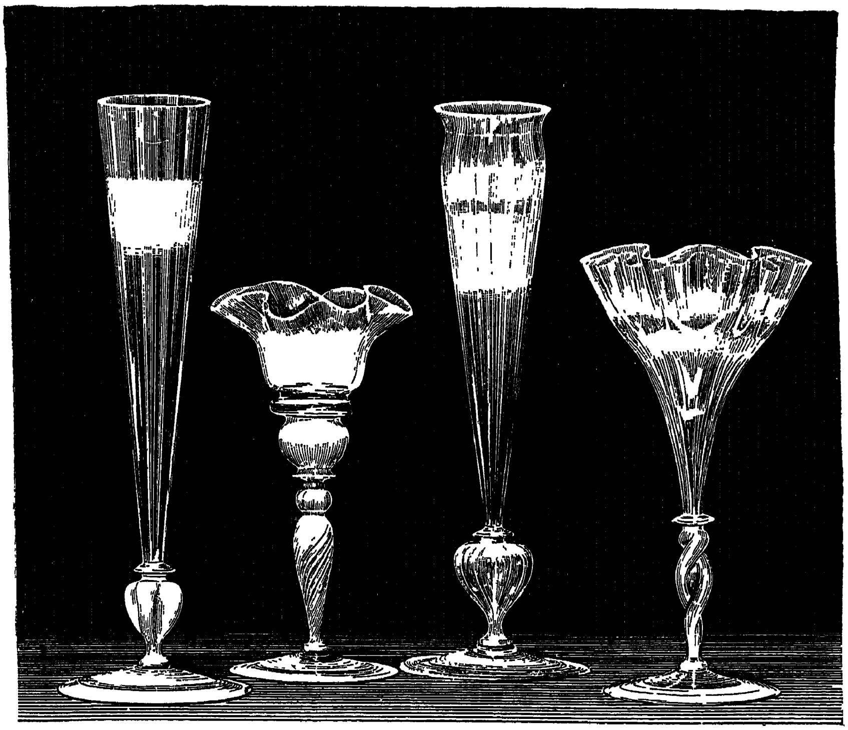

FIG. 2.—Opal Vases: figure on the right has naturally folded edges.

In the Paris Exhibition of 1900 surface decoration was the prominent feature of all the exhibits of table-glass. The carved or "cameo" glass, introduced by Thomas Webb of Stourbridge in 1878, had been copied with varying success by glass-makers of all nations. Frequently the surface had been dulled by acid so as to produce a "satin" finish. M. Émile Gallé and Daum Frères of Nancy exhibited

FIG. 3.—Whitefriars Glass.

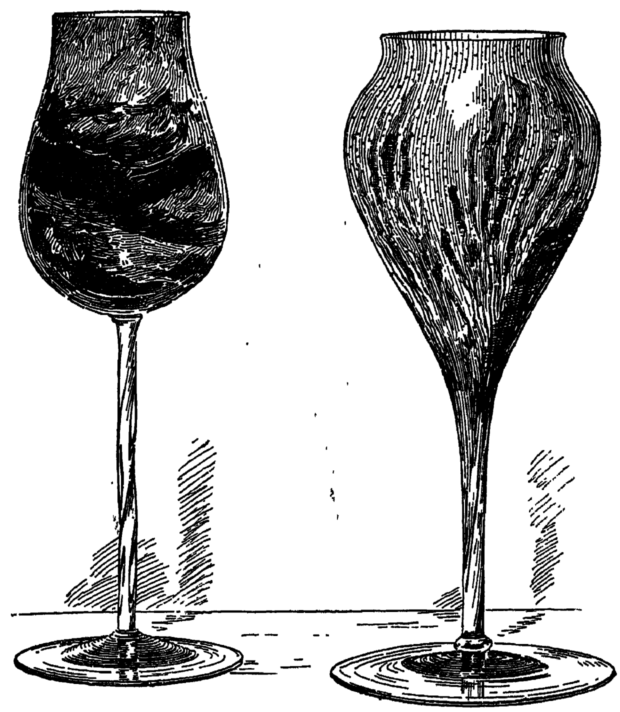

FIG. 4.—Whitefriars Glass.

specimens of this form of decoration possessing considerable beauty. The so-called "Favrile" glass of Messrs Tiffany of New York owes its effect entirely to surface colour and lustre (Fig. 6). The vases of Karl Koepping of Berlin are so graceful and so fragile that they appear to

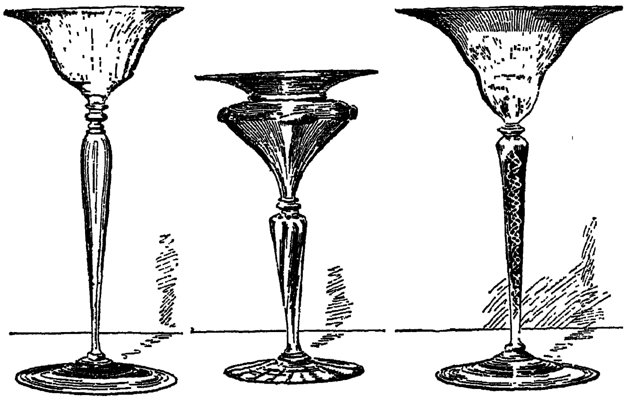

FIG. 5.—Whitefriars Glass.

be creations of the lamp-worker rather than of the glass-blower (see PLATE). Through the absence of exhibits of British table-glass it was impossible to determine the position it occupies in relation to that of other nations.

The existence of the craft of glass-blowing is threatened by three dangers. 1. There is the difficulty of attracting recruits. Boys are rightly forbidden to commence work at the furnace until they are fourteen. Commencing at this age, only those who are exceptionally quick attain the dexterity which is essential to a first-class workman. 2. To meet the demand for regularity and excessive lightness in table-glass, many of the simpler articles are now blown in moulds. The training which the fashioning of simpler forms by hand affords is thus lost. 3. The demand for cheap table-glass has encouraged the use of "pressed glass" and the introduction of automatic blowing machines from the United States.

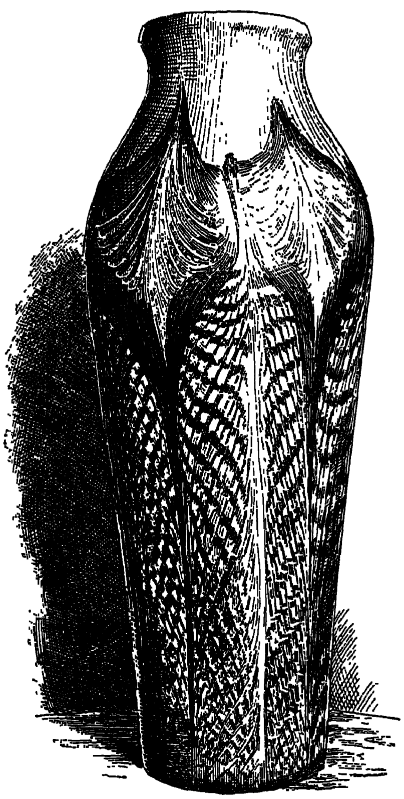

Fig. 6.—Tiffany Glass Vase.

Tube.—In modern thermometry instruments of extreme accuracy are required, and researches have been made, especially in Germany and France, to ascertain the causes of variability in mercurial thermometers, and how such variability is to be removed or reduced. In all mercurial thermometers there is a slight depression of the ice-point after exposure to high temperatures; it is also not uncommon to find that the readings of two thermometers between the ice- and boiling-points fail to agree at any intermediate temperature, although the ice- and boiling-points of both have been determined together with perfect accuracy, and the intervening spaces have been equally divided. It has been proved that these variations depend to a great extent on the chemical nature of the glass of which the thermometer is made. Special glasses have therefore been produced, by M. Tonnelot in France and at the Jena glassworks in Germany, expressly for the manufacture of thermometers for chemical and physical measurements.

The following are the analyses :—

	SiO_2	Na_2O	K_2O	CaO	Al_2O_3	Fe_2O_3	B_2O_3	ZnO	SO_3	Depression of Ice-point
Tonnelot's "Verre dur."	71·45	11·17	0·30	14·52	12·6	0·20	..	..	0·74	0·07
Jena glass—										
xvi–iii . .	67·5	14 0	..	7·0	2·5	..	2·0	7·0	..	0·05
59–iii . . .	72 0	11·0	..	..	5·0	.	12·0	..	..	0·02

Since the discovery of the Röntgen rays, experiments have been made to ascertain the effects of the different constituents of glass on the transparency of glass to X-rays. The oxides of lead, barium, zinc, and antimony are found perceptibly to retard the rays. The Jena glassworks manufacture two glasses for making X-ray tubes :—

	SiO_2	B_2O_3	Al_2O_3	Na_2O
I. . .	71·0	14·0	5·0	10·0
II. . .	39·6	30·0	20·0	10·0

Sheet Glass.—The following are analyses of sheet glass :—

	SiO_2	CaO	Na_2O	$Al_2O_3 + Fe_2O_3$
English . .	72·00	13·00	13·00	2·0
French . .	71·90	13·60	13·10	1·40

The materials used are sand, chalk or limestone, sulphate of soda; a small quantity of powdered anthracite or charcoal is added.

Regenerative gas-furnaces with tanks are generally used. The tanks are provided with one, two, or three floating bridges, and there are floating fireclay rings, within which the molten glass is kept clear by skimming, and from the centre of which the molten glass is gathered for working. Owing to the high temperature attainable with gas furnaces, and the greater purity of the materials used, the scum of "glass-gall" or "sandiver," which in old times rose to the surface, and was a constant source of trouble, is almost unknown. In many manufactories a separate furnace is used as a source for the heat required in manipulation. This arrangement prevents loss of heat from the melting furnace, and enables the temperature to be more regularly maintained. A well-regulated temperature improves the quality of the glass, and is sufficient compensation for the extra expenditure on fuel. The regular working of the melting furnace adds greatly to the convenience of the workmen, as they can work throughout the week in regular eight-hours shifts.

The use of compressed air for blowing the sheet-glass cylinders has been introduced, but has not been generally adopted.

Coloured Glass for Windows.—The production of coloured glass for "mosaic" windows has become a separate branch of glass-making. Charles Winston, after prolonged study of the coloured windows of the 13th, 14th, and 15th centuries, convinced himself that no approach to the colour effect of these windows could be made with glass which is thin and even in section, homogeneous in texture, and made and coloured with highly refined materials. To obtain the effect it was necessary to reproduce as far as possible the conditions under which the early craftsmen

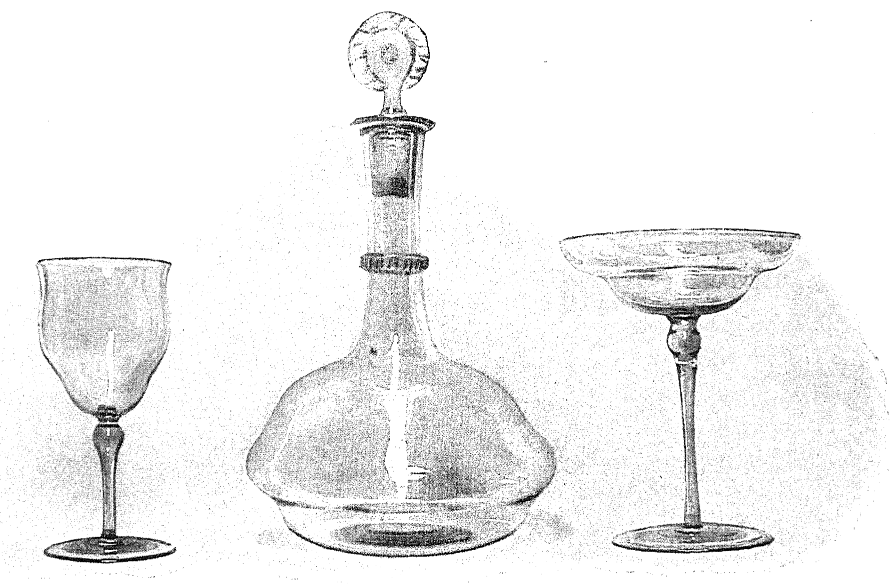

Table Glass. Designed by T. G. Jackson (in 1870).

Table Glass. Designed by William Morris (about 1872).

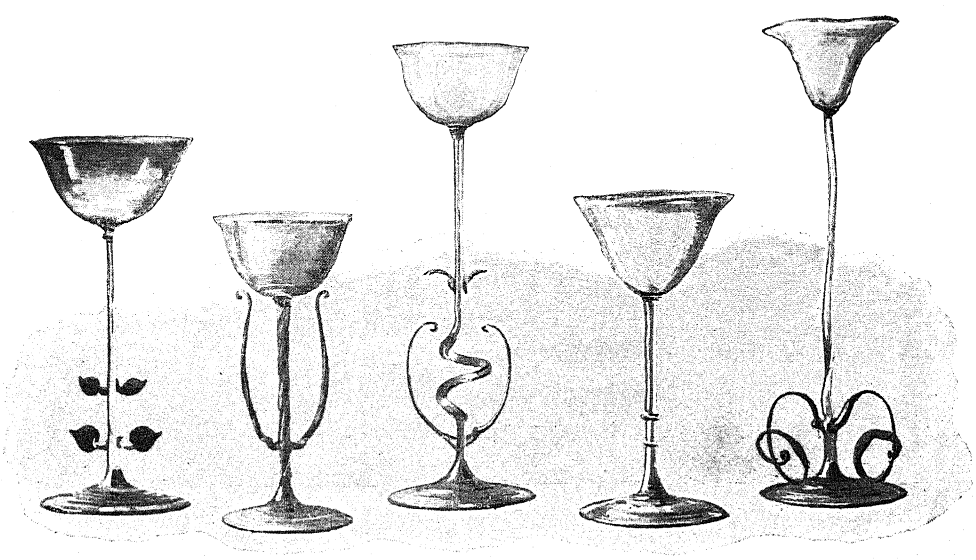

Table Glass. Designed by Koepping of Berlin (1900).

worked, and to create scientifically glass which is impure in colour, irregular in section, and non-homogeneous in texture. The glass is made in cylinders and in "crowns" or circles. The cylinders measure about 14 inches in length by 8 inches in diameter, and vary in thickness from one-eighth to three-eighths of an inch. The "crowns" are about 15 inches in diameter, and vary in thickness from one-eighth to half an inch, the centre being the thickest. The glass, thus made, gives all the life and variety that the artist can legitimately require, and coloured glasses are made which are certainly not unequal to the old. Mr E. J. Prior has introduced an ingenious method of making small oblong and square sheets of coloured glass, which are thick in the centre and taper towards the edges, and which have one surface slightly roughened and one brilliantly polished. Molten glass is blown into an oblong iron mould about 12 inches in depth and 6 inches in width. A hollow rectangular bottle is formed, the base and sides of which are converted into sheets. The outer surface of these sheets is slightly roughened by contact with the iron mould. Small slabs or sheets with an irregular section are also made by pressing molten glass on to flat moulds marked with slight irregularities. Large sheets of irregularly corrugated glass are made by a rolling machine. The molten glass passes between two rollers, one of which is engraved with sinuous indentations. This rolled and mechanically undulated glass, especially when it is opalescent and streaked with colour, is at the present time popular on the Continent and in the United States. Many of the coloured windows at the Paris Exhibition of 1900 were made of this glass, and contained representations by means of streaks of colour of sunset and sunrise, as well as of fruits, flowers, and trees. There were occasional happy effects of colour, but the style and material are too suggestive of confectionery.

III. Glass Mechanically Pressed or Blown.

Plate Glass.—The following are analyses of plate glass :—

	SiO_2	CaO	Na_2O	Al_2O_3	Fe_2O_3
French . .	71·80	15·70	11·10	1·26	0·14
English . .	70·64	16·27	11·47	0·70	0·49

The materials used are sand, limestone, sulphate of soda; a small quantity of powdered anthracite or charcoal is added. Regenerative gas furnaces are almost universally employed. The same crucibles are used both for melting and casting; they hold from 1 to 1½ tons of molten glass, and weigh from 7 to 9 cwt. Contact with the molten glass causes the tables to expand, and the expansion of the tables gives to the glass plates a curved section. This curvature is reduced by building the casting tables of many comparatively small slabs of iron, instead of two or three, as was formerly the custom.

Pressed Glass.—The following is an analysis of a specimen of English "pressed" glass :—

	SiO_2	Na_2O	CaO	BaO	Al_2O_3	Fe_2O_3
English .	70·68	18·38	5·45	4·17	0·33	0·20

The materials used at Gateshead are sand, sulphate of soda, nitrate of soda, lime-spar, and carbonate of barium. The use of red-lead has been discontinued. At Pittsburg, United States, the materials are sand, soda-ash, nitrate of soda, and lime (crushed and burnt). At Gateshead the old-fashioned coal furnaces are still used. The moulds are made of cast iron. Oil furnaces with steam-blast are used for polishing the goods after they have been pressed The presses are generally worked by hand. Steam power, however, has been applied to some of the heavier ones. The secretary of the National Glassworks at Pittsburg writes: "Most of the work done in America in table-ware, tumblers, &c., is produced by hand-presses, as it is necessary for the operator to know by touch whether the plunger has pressed the glass to the proper point in the mould. Natural gas has been very largely used for the past ten years in the manufacture of glass. Continuous tank furnaces are used for the commoner grades of pressed glass."

Glass Bottles partly Pressed and partly Blown by Compressed Air.—The following is an analysis of a specimen of light green English "bottle" glass :—

	SiO_2	Al_2O_3	Fe_2O_3	CaO_2	Na_2O
English . .	69·15	2·38	0·69	15·38	12·17

The materials used are sand, Derbyshire limestone, chalk, sulphate, and carbonate of soda. Gas regenerative tank furnaces are generally used. Ashley's patent bottle-making machine combines the process of pressing with a

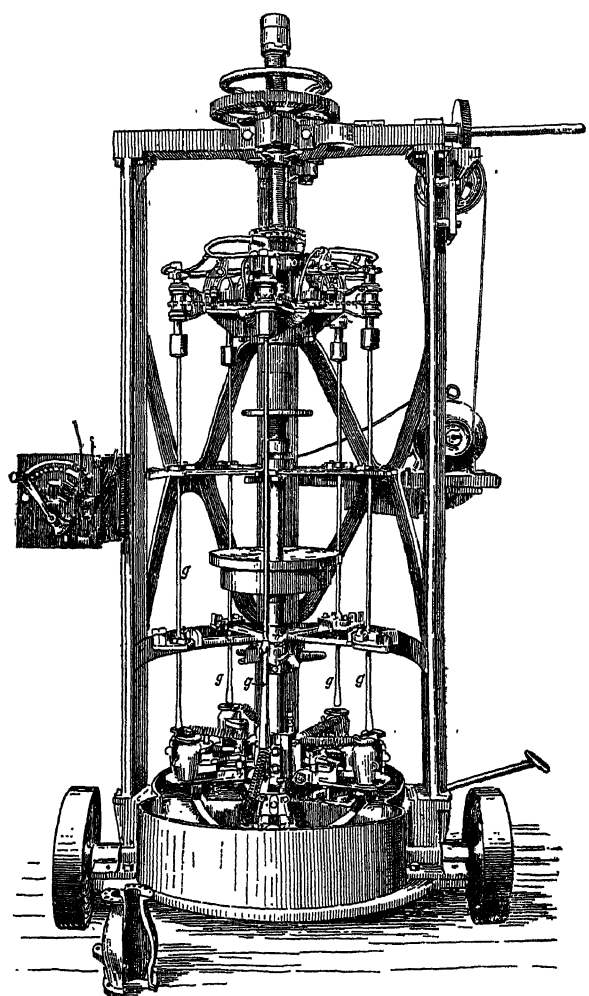

Fig. 7.—Owens's Glass-blowing Machine.
g. g. g. blowing-irons.

plunger, with that of blowing by compressed air. The neck of the bottle is first formed by the plunger, and the body is subsequently blown out by compressed air admitted through the plunger. A sufficient weight of molten glass to form a bottle is gathered and put

in a funnel placed over and giving access to a mould which shapes the outside of the neck. A plunger is forced upwards into the glass contained in the neck-mould and forms the neck. The funnel is removed, and the plunger, neck-mould, and mass of molten glass attached to the neck are inverted. A bottle mould rises and envelops the mass of molten glass. Compressed air is admitted through the plunger in the neck, forces the molten glass to take the form of the bottle mould, and completes the bottle. A single machine can be made to produce nine gross of bottles in a day.

Glass Blown by Compressed Air.—Works have been built at West Bromwich for the manufacture of tumblers, chimneys, bottles, and electric lamp bulbs by means of the automatic glass-blowing machine (Fig. 7) patented by Michael Owens of Toledo, U.S.A. These machines take the place of human glass-blowers. The only manual operations are: (1) Gathering the molten glass at the end of a blowing-iron; (2) placing the blowing-iron in the machine so that, whilst the mouth-piece is in contact with an air-jet, the mass of molten glass hangs within the sections of an open mould; (3) removing the blowing-iron with the finished article attached. Each machine consists of a revolving table carrying five or six moulds. The moulds are opened and closed by "cams" actuated by compressed air. As soon as a blowing-iron is in contact with an air-jet, the sections of the mould close upon the molten glass and the compressed air forces the glass to take the form of the mould. A large pipe carrying compressed air runs round the works, and the blowing machines are connected with the pipe by flexible tubes. It is claimed that these machines can turn out seven tumblers or five lamp chimneys per minute.

(H. J. P.)

Glass, Stained.—The art of what is called glass painting—though in reality a combination of glazing and painting goes to the making of a stained glass window—may be claimed as mediæval. It arose and was developed in connexion with Gothic architecture; painted glass, indeed, culminated in the 16th century, but the art throve only so long as artists of the Renaissance worked on the mosaic principle of the Middle Ages. Step by step with their departure from the consideration of a window as primarily stained glass, and their reliance upon painting only, the art declined. Its reawakening in England was part of the Gothic revival; and the Gothic revival determined the direction which modern glass should take. Early Victorian work was tentative, interesting, not for its artistic merit, but as marking the steps of recovery—witness the work of Willement, in the choir of the Temple Church; of Ward and Nixon, in the south transept of Westminster Abbey; and of Wailes, in the House of Lords. The cartoons for this last were drawn by Oliphant from sketches by Pugin, who in his day exercised considerable influence over the art, and by John Powell (Hardman & Co.), an able artist, who was content to walk, even after his master's death, reverently in his footsteps. Charles Winston, again, whose *Hints on Glass Painting* was the first real contribution towards the understanding of Gothic glass, and who, by the aid of Powell's (of Whitefriars), succeeded in getting glass very like the old in texture and colour, was more learned in ancient instances than appreciative of modern design. So from the beginning of its recovery glass fell into the hands of men less in sympathy with art than with archæology. The artists foremost in the Gothic revival (Butterfield, Street, Burges, &c.) were infected with the same spirit; and, as they had the placing of commissions for windows, they controlled the policy of glass painters. Thus designers, whatever their originality, were constrained to work in a manner contrary to their individual bias, and to fill churches with mock-mediæval windows, the interest in which died with the illusion about a Gothic revival. But they knew their trade, and when an artist like John Clayton (Clayton & Bell), master of a whole school of later glass painters, took a window into his hands (St Augustine's, Kilburn; Truro Cathedral; King's College Chapel, Cambridge) the result was a work of art from which we may gather what such men might have done had they been left to follow the bent of their own genius. It is necessary to refer to this, because it is popularly supposed that whatever is best in recent glass is due to the Romantic movement. The charms of Burne-Jones's design and of Morris's colour place the windows done by them among the triumphs of modern decorative art. But Morris was neither foremost in the reaction, nor quite such a master of the material he was working in as he showed himself in other crafts. Other artists to be mentioned in connexion with glass design are—Clement Heaton, Bayne, Westlake, and Henry Holiday.

Foreign work, as compared with modern English, shows a less just appreciation of glass. In Germany, King Louis of Bavaria enlisted Cornelius and Kaulbach as designers for it (Aix-la-Chapelle, Cologne, Glasgow). In France the Bourbons employed Ingres, Delacroix, Vernet, and Flandrin (Dreux). But though the windows they designed were painted with the skill characteristic of Munich and Sèvres, the glass, according as it was left bare or laden with paint, was either crude or dull, lacking the character of glass. In Belgium happier results were obtained, Capronnier's window at Brussels being not unworthy of the series by Van Orley, which it supplements; but foreign artists failed at the best to appreciate the quality of glass; they put better draughtsmanship into their windows than English designers, and painted them better, but they missed the glory of translucent colour.

In America, John La Farge, finding English material not dense enough, produced pot-metal more heavily charged with coloured oxides, and more wilfully streaked, mottled, and otherwise quasi-accidentally varied than European manufacture—opalescent, too, and more like agate or onyx than jewels. It was also an American idea to make glass in lumps and chip it into flakes, to corrugate it, to blow it into shapes, or to pull molten glass out of shape—to make, in fact, material safely to be trusted only in the hands of an artist of reserve. La Farge and L. Tiffany have turned it to beautiful account; but even they have put it to more pictorial purpose than it can properly fulfil. The design to which it obviously lends itself is a form of ornament severe even to the verge of the barbaric.

Mere painting, whether on pieces of pot-metal afterwards to be leaded together, or upon single sheets of plate, has been carried as far as it can go. In the one case there is always the discrepancy between delicate painting and

harsh lead lines; in the other, there is so little of the real quality of glass in the result, that there is no excuse for the production of so fragile a picture, lacking, as it must, the qualities peculiar to painting proper, as may be seen in the wonderful but most unsatisfactory series of pictures painted at Sèvres for the chapel at Dreux (sheets of plate each 4 by $2\frac{1}{2}$ feet).

Of late years each country has been learning from the others, and the newest effort is very much in one direction. It seems to be agreed that a window begins with glazing, that the all-needful thing is beautiful glass, and that painting may be reduced to a minimum, may even (owing to new developments in the making of glass) be dispensed with altogether.

The present tendency seems to be not merely in the direction of mosaic, but of carrying the glazier's art further than has been done before, rendering even figure subjects and landscapes in leaded glass. The limitations of mere glazing are obvious—only a very partial view, for example, of the human face can be expressed in this fashion—but a way out of the difficulty was shown at Paris (1900) by M. Tournel, who fused coloured tesseræ on to larger pieces of colourless glass, with a flux of powdered glass between them. There would be no advantage in building up whole windows in this way, but for the rendering of the flesh, &c., in a window for the most part leaded, this use of tesseræ, and even of small-shaped pieces fused on to white, seems to supply just what is wanted.

A freer hand is given to the glass painter to-day, partly because his work is no longer exclusively ecclesiastical. Domestic glass being now a very important industry, the practices of men employed upon it seriously affect the methods of those engaged upon church work. Moreover, the recognition of the artistic position of craftsmen in general makes it possible for an artist to devote himself to glass without sinking to the rank of a mechanic; and artists begin to realize the scope glass offers to them. Design is all-important. And design is adequate in proportion as it has nothing to lose and everything to gain by translation into glass. It must necessarily take into account the capacities of the material, asking of it only what it can do, and bringing out the qualities in which it excels—the purity, the brilliancy, the translucency, the beauty of colour in which it is supreme. (L. F. D.)

Glastonbury, a municipal borough and market-town in the eastern parliamentary division of Somersetshire, England, 5 miles south-west of Wells by rail. The church of St Benedict and St John's Church tower have been restored. In 1892 the remains of a prehistoric marsh village, consisting of sixty mounds within a space of five acres, were discovered close by the town. The relics found there and in other localities in the neighbourhood have been deposited in the Antiquarian Museum, begun in 1887. There are a Roman Catholic college for missionaries, a Roman Catholic chapel, and various Nonconformist chapels. There are manufactures of sheepskin rugs and leather gloves and shoes. Area, 5000 acres. Population (1881), 3719; (1901), 4016.

Glatz, a fortified town of Prussia, province of Silesia, on the Neisse, 58 miles by rail south-south-west from Breslau. Breweries and machinery factories have been added to its industries. A bronze statue of the Emperor William I. was unveiled in 1898. The fortifications of the town were razed in 1891. Population (1885), 13,588; (1900), 14,918.

Glauchau, a town of Germany, on the Mulde, 17 miles by rail west of Chemnitz, in the circle of Zwickau, kingdom of Saxony. It has important manufactures of woollens and half-woollens, 9 weaving mills, over 20 dye, cloth-dressing, yarn-washing, and print works, 2 spinning mills, several pattern-designing works, and a weaving-implement factory. Population (1890), 23,405; (1900), 25,674.

Gleichen, two groups of castles in Germany. (1) A group of three, situated each on an isolated hill in Thuringia, between Gotha and Erfurt. Of the three only one is inhabited, namely, Wachsenburg (1358 feet above sea-level), belonging to the duke of Saxe-Coburg-Gotha, and containing collections of weapons, pictures, &c. It is said to have been founded about 935, and was sold to the landgrave of Thuringia in 1368. The other two, Gleichen (1221 feet) and Mühlberg (1309 feet), are ruins. Both were unsuccessfully besieged by the Emperor Henry IV. in 1088. The former is best known from the romantic legend of the count of Gleichen, a Crusader, who was allowed to live with two wives at the same time (see Musæus, *Volksmärchen*, "Melechsala"). The castle of Mühlberg existed as early as 704. (2) The other group of two castles, Neu-Gleichen and Alt-Gleichen, both in ruins, crown two isolated hills (1394 and 1404 feet respectively) about 2 miles south-east from Göttingen.

Glenelg, a South Australian watering-place, $6\frac{1}{2}$ miles south-south-west of Adelaide, on Holdfast Bay. It is a popular summer resort, connected by two railway lines with Adelaide. In the vicinity is the "Old Gum Tree," under which South Australia was proclaimed British territory by Governor Hindmarsh in 1836. Population (1901), 3949.

Glens Falls, a village of Warren county, New York, U.S.A., in 43° 18′ N. and 73° 39′ W., on the Hudson river and on the Delaware and Hudson Railway, at an altitude of 343 feet. It has fine water power in the falls, which is utilized in lumber, shingle, and lath mills, paper mills, and iron and steel works. In the immediate neighbourhood are many lime-kilns. Population (1880), 4900; (1890), 9509; (1900), 12,613, of whom 1762 were foreign-born.

Glogau, a fortified town of Prussia, province of Silesia, on the Oder, 59 miles north-west from Breslau by the railway to Frankfort-on-the-Oder. A new quarter has grown up on the south-east of the old fortified *enceinte*. Population (1885), 20,027; (1900), 22,136.

Glossop, a municipal borough and market-town in the High Peak parliamentary division of Derbyshire, England, 58 miles north-north-west of Derby by rail. Recent erections are the free library, the public baths, a technical school (1900), and Wood's Hospital. Howard Park was formed in 1887. Area of borough, 3033 acres. Population (1881), 19,574; (1901), 21,526.

Gloucester, a city and seaport of Essex county, Massachusetts, U.S.A., in latitude 42° 36′ N. and 70° 39′ W., on Cape Ann, and a branch of the Boston and Maine Railway. It includes, besides the community of Gloucester, several small places, Annisquam, Bayview, Lanesville, East and West Gloucester, and Riverdale. The city includes an area of 34 square miles; most of this is uneven, and the bordering coast is rocky. Gloucester has an excellent harbour and some commerce, but the principal business is fishing. In this industry it is the most important place in the United States, and most of the adult males are engaged in it. There were employed in it, in 1895, 380 vessels, 2442 boats, and 5500 men. The product was valued at $3,212,985. An industry of secondary importance is the quarrying of the granite with which the city is underlaid. The manufactures are not extensive. In 1895 the capital invested was $3,003,256, employing 1980 hands, with a product valued at $5,590,366. Of this, by far the largest item was canned and preserved fish.

The coast is very picturesque, and it has become a favourite seaside resort, especially for artists, who prefer the point on the east side of the harbour, in the village of East Gloucester. Population (1880), 19,329; (1890), 24,651; (1900), 26,121, of whom 8768 were foreign-born. The death-rate in 1900 was 14·9.

Gloucester, a city of Camden county, New Jersey, U.S.A., in 39° 53′ N. and 75° 07′ W., on the eastern side of the Delaware river, opposite Philadelphia. It is connected with Philadelphia by ferry, and has two railways, the Atlantic City and the West Jersey and Seashore. Population (1880), 5347; (1890), 6564; (1900), 6840, of whom 1094 were foreign-born.

Gloucester, a city, county of itself, municipal and parliamentary borough, port, and county town of Gloucestershire, England, in the Tewkesbury parliamentary division of the county, on the left bank of the river Severn, 33 miles north-east of Bristol by rail. Alternately with Worcester and Hereford, a triennial musical festival is held here. In recent years the Shire Hall has been enlarged at a cost of £11,750; the Guildhall built at a cost of £31,500; the corn exchange enlarged and converted into the post office; a free library built, and a county council dairy school established. Between the years 1873 and 1890 the sum of £13,000 was expended on the restoration of the cathedral. In 1897 funds, estimated at £10,000, were collected for further expenditure, and the north and west alleys of the cloisters were thoroughly repaired. Gloucester, declared a port in 1882, is reached from the Severn by a ship canal (the Berkeley) 16½ miles in length. The registered shipping in 1898 consisted of 154 vessels of 7563 tons. In that year 4445 vessels entered the port with 510,874 tons, and 4478 vessels cleared with 493,856 tons. A harbour board was formed in 1890 to maintain, regulate, and light a harbour in the Severn estuary. Since 1885 the city has returned only one member to Parliament. Area, 1437 acres. Population (1881), 36,513; (1901), 47,943.

Gloucestershire, a west midland county of England, bounded on the S.E. by Wiltshire, on the S. by Somersetshire, on the W. by Monmouthshire, on the N.W. by Herefordshire, on the N. by Worcestershire and Warwickshire, and on the E. by Oxfordshire.

Area and Population.—The area of the ancient county is 795,734 acres or 1243 square miles, with a population in 1881 of 572,341, and in 1891 of 599,947, of whom 281,012 were males and 318,935 females, the number of persons per square mile being 483, and of acres to a person 1·32. The area of the administrative county, as given in the census returns of 1891, was 796,731 acres, with a population in 1891 of 645,574; but in 1896 considerable additions were made to its area by the transference from Warwickshire of the part of the parish of Batsford in Warwickshire, and by the transference from Wiltshire of the parishes of Kemble, Poole Keynes, and Somerford Keynes. The area of the registration county in 1891 was 714,763 acres, with a population of 548,886, of which 360,705 were urban and 188,181 rural. Within the registration area the increase of population between 1881 and 1891 was 4·52 per cent. The excess of births over deaths between 1881 and 1891 was 64,020, and the increase of the resident population was 23,717. In 1901 the population of the ancient county was 634,666. The following table gives the numbers of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	4113	16,485	9938	423	392
1890	4315	15,723	9760	328	311
1898	4436	14,880	9116	276	275

The number of marriages in 1899 was 5034; of births, 17,809; and of deaths, 11,178.

The following table gives the marriage-, birth-, and death-rate per 1000 of the population, with the percentage of illegitimate births, for a series of years:—

	1870–79.	1880.	1880–89.	1890.	1888–97.	1898
Marriage-rate	17·2	15·7	15·3	15·8	15·4	15·7
Birth-rate	32·6	31·5	30·1	27·6	27·8	26·4
Death-rate	20·4	19·0	17·9	17·8	17·4	16·1
Percentage of Illegitimacy	4·8	4·9	4·8	3·9	4·0	3·7

In 1891 there were in the county 435 natives of Scotland, 735 natives of Ireland, and 392 foreigners.

Constitution and Government.—The ancient county comprises five parliamentary divisions, and it also includes the parliamentary borough of Gloucester, returning one member, part of the borough of Cheltenham, returning one member, and the greater part of the borough of Bristol, which returns four members. The administrative county contains four municipal boroughs: the city of Bristol (328,842), Cheltenham (49,439), Gloucester (47,943), and Tewkesbury (5419). Bristol and Gloucester are county boroughs. The following are the urban districts: Awre (1096), Charlton Kings (3806), Cirencester (7536), Coleford (2541), Horfield (1435), Kingswood (11,961), Nailsworth (3028), Newnham (1184), Stow-on-the-Wold (1386), Stroud (9188), Tetbury (1989), and Westbury-on-Severn (1866). The Forest of Dean is for forestry purposes under the jurisdiction of the Crown, and the hundred of the duchy of Lancaster is for some purposes under the jurisdiction of the duchy of Lancaster. Gloucestershire is in the Oxford circuit, and assizes are held at Gloucester. The boroughs of Bristol, Gloucester, and Tewkesbury have separate commissions of the peace and separate courts of quarter sessions. The ancient county—which is chiefly in the diocese of Gloucester—contains 397 ecclesiastical parishes and districts, with parts of ten others.

Education.—Cheltenham is the seat of a famous grammar school. There are a residential training college (Church of England) for schoolmasters, another at Bristol (Diocesan), and two training colleges (Church of England and Ladies' College) for schoolmistresses. There are at Bristol a district institution for deaf and dumb, a school board deaf school, and an asylum and school of industry for the blind. The number of elementary schools on 31st August 1899 was 541, of which 116 were board and 425 voluntary schools, the latter including 375 national Church of England schools, 11 Wesleyan, 11 Roman Catholic, and 28 "British and other." The average attendance at board schools was 41,321, and at voluntary schools 61,653. The total school board receipts for the year ending 29th September 1899 were over £212,666. The income under the Agricultural Rates Act was over £1925.

Agriculture.—Nearly seven-eighths of the total area of the county is under cultivation, and of this nearly four-sevenths is in permanent pasture, both cattle and sheep being largely raised. A feature of the county is its apple and pear orchards, chiefly for the manufacture of cider and perry, which are attached to nearly every farm, and cover altogether more than 19,000 acres. Nearly 60,000 acres are under wood. The acreage under wheat nearly equals the combined acreages under barley and oats; and turnips, &c., occupy about three-fourths of the green crop acreage, potatoes occupying only about a twelfth. About 1500 acres are under small fruit. The following table gives the larger main divisions of the cultivated area at intervals from 1880:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	653,828	160,852	60,152	89,067	324,908	18,823
1885	659,011	146,659	60,610	98,064	341,239	12,408
1890	659,336	135,949	54,435	89,869	369,023	9,116
1895	656,488	120,603	50,293	88,068	387,092	8,611
1900	661,441	121,495	47,035	89,214	398,718	4,431

The following table gives particulars regarding the principal live stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	25,779	112,292	36,230	354,621	52,171
1885	26,455	129,926	43,506	393,149	68,353
1890	27,268	121,336	41,640	375,712	81,094
1895	27 737	109,786	38,307	347,011	83,619
1900	27,530	124,708	39,068	364,785	67,438

Industries and Trade.—According to the annual report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 60,427,

as compared with 59,678 in 1896. Of these 5830 were employed in textile factories, the majority of whom (3539) were engaged in the woollen manufacture carried on at Bisley, Eastington, Edge, Ebley, Minchinhampton, Nailsworth, North Nibley, Stonehouse, Stroud, and Wotton-under-Edge; the cotton industry employed 1355. The number employed in non-textile factories was 43,173, there being an increase between 1895 and 1896 of 10·2 per cent., and between 1896 and 1897 of 0·1. Of these 8538 were employed in clothing industries, 7097 in the manufacture of machine appliances, conveyances, and tools, 5752 in food industries, 4370 in the manufacture of paper, &c., and 1497 in furniture-making, &c.; pottery and glass are also manufactured. Workshops employed 11,424, of whom 6486 were employed in clothing industries and 1316 in those of furniture, &c. For the export and import maritime trade see under BRISTOL and GLOUCESTER, city. The total number of persons employed in mines and quarries in 1899 was 8775. In the same year 254,173 tons of clay were raised, 171,270 tons of limestone, and 123,534 tons of sandstone. Strontium sulphate is dug from shallow pits in the red marl in Gloucestershire and Somersetshire, the total quantity obtained in the two counties in 1899 being 12,629 tons, valued at £6314. The following table gives the coal and ironstone produced in 1890 and 1899:—

	1890.		1899.	
	Tons.	Value.	Tons.	Value.
Coal . .	1,419 616	£716,100	1,528,014	£789,474
Ironstone .	65,611	26,244	26,101	12,516

London, 1895–97. See also *Transactions of the Bristol and Gloucestershire Archæological Society.* (T. F. H.)

Gloversville, a city of Fulton county, New York, U.S.A., in 43° 03′ N. and 74° 22′ W., on a small branch of the Mohawk river, and on the Fonda, Johnstown, and Gloversville Railway; altitude 1000 feet. Gloversville derives its name from its principal industry, the glove manufacture, for which it is the chief centre in the United States. It was incorporated as a village in 1851, and received a city charter in 1890. Population (1880), 7133; (1890), 13,864; (1900), 18,349, of whom 2542 were foreign-born and 216 were negroes. The death-rate in 1900 was 11·8.

Glückstadt, a seaport town of Prussia, province of Schleswig-Holstein, on the right bank of the Elbe, 33 miles north-west from Hamburg by rail. The town hall, built in 1642, was entirely rebuilt in 1873. Here are a school of seamanship, and railway workshops, shipbuilding, &c. The port is free. Population (1885), 5483; (1900), 6586.

Gmünd, a town of Würtemberg, Germany, on the river Rems, 32 miles by rail east of Stuttgart. It is a seat of the jewellery and silversmiths' industries, of wood-carving and turning, and cotton-weaving, and has a trade in fruit and hops. There are an industrial art museum and several benevolent institutions. Population (1885), 15,321; (1900), 18,673.

Gmunden, the chief town of the Salzkammergut, in Upper Austria, and the principal depôt of the State Salt Monopoly, situated at the efflux of the Traun river, from the lake of the same name. It is much frequented as a health and summer resort, and has a variety of lake-, brine-, vegetable-, and pine-cone baths, a hydropathic establishment, inhalation chambers, whey cure, &c. Its principal resource, in addition to the salt industry, is the entertainment of its thousands of visitors. Population (1890), 6476; (1900), 7126.

Gneist, Heinrich Rudolf Hermann Friedrich von (1816–1895), German jurist and politician, was born at Berlin on the 13th of August 1816, the son of a judge attached to the "Kammergericht" (Court of Appeal) in that city. After receiving his school education at the Gymnasium at Eisleben in Prussian Saxony, he entered the University of Berlin in 1833 as a student of jurisprudence, and became a pupil of the famous Roman law teacher von Savigny. Proceeding to the degree of *doctor juris* in 1838, young Gneist immediately established himself as a "privat-docent" in the faculty of Law. He had, however, already chosen the judicial branch of the legal profession as a career, and having while yet a student acted as "auscultator," was admitted "assessor" in 1841. He soon found leisure and opportunity to fulfil a much-cherished wish, and spent the next few years on a lengthened tour in Italy, France, and England. He utilized his "Wanderjahre" for the purposes of comparative study, and on his return in 1844 was appointed extraordinary professor of Roman law in Berlin University; and thus began a professorial connexion which ended only with his death. The first-fruits of his activity as a teacher were seen in his brilliant work, *Die formellen Verträge des heutigen römischen Obligationen-Rechtes* (Berlin, 1845). *Pari passu* with his academic labours, he continued his judicial career, and became in due course successively assistant judge of the Superior Court and of the Supreme Tribunal. But to a mind constituted such as his, the want of elasticity in the procedure of the courts was galling. "Brought up," he tells, in the preface to his *Englische Verfassungs-Geschichte*, "in the laborious and rigid school of Prussian judges, at a time when the duty of formulating the matter in litigation was entailed upon the judge who personally conducted the pleadings, I became acquainted both with the advantages possessed by the Prussian bureau system as also with its weak points." Feeling the necessity for fundamental reforms in legal procedure, he published, in 1849, his *Trial by Jury*, in which, after pointing out that the origin of that institution was common to both Germany and England, and showing in a masterly way the benefits which had accrued to the latter country through its more extended application, he pleaded for its freer admission in the tribunals of his own country. The period of "storm and stress" in 1848 afforded Gneist an opportunity for which he had yearned, and he threw himself with ardour into the constitutional struggles of Prussia. Although his candidature for election to the National Assembly of that year was unsuccessful, he felt that "the die was cast," and deciding for a political career, retired in 1850 from his judicial position. Entering the ranks of the National Liberal party, he began both in writing and speeches actively to champion their cause, now busying himself pre-eminently with the study of constitutional law and history. In 1853 appeared his *Adel und Ritterschaft in England*, and in 1857 the *Geschichte und heutige Gestalt der Aemter in England*, a pamphlet primarily written to combat the Prussian abuses of administration, but for which the author also claimed that it had not been without its effect in modifying certain views that had until then ruled in England itself. In 1858 Gneist was appointed ordinary professor of Roman law, and in the same year commenced his parliamentary career by his election for Stettin to the Abgeordnetenhaus (House of Deputies) of the Prussian Landtag, in which assembly he sat thenceforward uninterruptedly until 1893. Joining the Left, he at once became one of its leading spokesmen. His chief oratorical triumphs are associated with the early period of his membership of the House; two noteworthy occasions being his violent attack (September 1862) upon the Government budget in connexion with the reorganization of the Prussian army, and his defence (1864) of the Polish chiefs of the (then) Grand Duchy of Posen, who were accused of high treason. In 1857–63 was published *Das heutige*

Englische Verfassungs und Verwaltungsrecht, a work which, contrasting English and German constitutional law and administration, aimed at exercising political pressure upon the Government of the day. In 1868 Gneist became a member of the North German Parliament, and acted as a member of the commission for organizing the Federal army, and also of that for the settlement of ecclesiastical controversial questions. On the establishment of German unity, his mandate was renewed for the Reichstag, and in this he sat, an active and prominent member of the National Liberal party, until 1884. In the Kulturkampf he sided with the Government against the attacks of the Clericals, whom he bitterly denounced, and whose implacable enemy he ever showed himself. In 1879, together with his colleague, von Hänel, he violently attacked the motion for the prosecution of certain Socialist members, which as a result of the vigour of his opposition was almost unanimously rejected. He was parliamentary reporter for the committees on all great financial and administrative questions, and his profound acquaintance with constitutional law caused his advice to be frequently sought, not only in his own but also in other countries. In Prussia he largely influenced legislation, the reform of the judicial and penal systems and the new constitution of the Evangelical Church being largely his work. He was also consulted by the Japanese Government when a constitution was being introduced into that country. In 1875 he was appointed a member of the Supreme Administrative Court ("Oberverwaltungsgericht") of Prussia, but only held office for two years. In 1882 was published his *Englische Verfassungs-Geschichte* (trans., "History of the English Constitution," London, 1886), which may perhaps be described as his *magnum opus.* It placed the author at once on the level of such writers on English constitutional history as Hallam and Stubbs, and supplied English literature with a text-book almost unrivalled in point of historical research. In 1888 one of the first acts of the ill-fated Emperor Frederick, who had always, as Crown Prince, shown great admiration for him, was to ennoble Gneist, and attach him as instructor in constitutional law to his son, the Emperor William II., a charge of which he worthily acquitted himself. The last years of his life were full of energy, and, in the possession of all his faculties, he continued his wonted academic labours until a short time before his death, which occurred at Berlin on the 22nd of July 1895.

As a politician, Gneist's career cannot perhaps be said to have been entirely successful. In a country where parliamentary institutions are the living exponents of the popular will he might have risen to a foremost position in the State; as it was, the party to which he allied himself could never hope to become more than what it remained, a parliamentary faction, and the influence it for a time wielded in the counsels of the State waned as soon as the Social-Democratic party grew to be a force to be reckoned with. It is as a writer and a teacher that Gneist is best known to fame. He was a jurist of a special type. To him law was not mere theory, but living force; and this conception of its power animates all his schemes of practical reform. As a teacher he exercised a magnetic influence, not only by reason of the clearness and cogency of his exposition, but also because of the success with which he developed the talents and guided the aspirations of his pupils. He was a man of noble bearing, religious, and imbued with a stern sense of duty. He was proud of being a "Preussischer Junker" (a member of the Prussian squirearchy), and throughout his writings, despite their liberal tendencies, may be perceived the loyalty and affection with which he clung to monarchical institutions. A great admirer and a true friend of England, to which country he was attached by many personal ties, he surpassed all other Germans in his efforts to make her free institutions, in which he found his ideal, the common heritage of the two great nations of the Teutonic race.

Gneist was a prolific writer, especially on the subject he had made peculiarly his own, that of constitutional law and history, and among his works, other than those above named, may be mentioned the following: *Budget und Gesetz nach dem constitutionellen Staatsrecht Englands* (Berlin, 1867); *Freie Advocatur* (*ibid.*, 1867); *Der Rechtsstaat* (*ibid.*, 1872, and 2nd edition 1879); *Zur Verwaltungsreform in Preussen* (Leipzig, 1880); *Das englische Parlament* (Berlin, 1886); in English translation, *The English Parliament* (London, 1886, 3rd edition 1889); *Die Militär-Vorlage von 1892 und der Preussiche Verfassungsconflikt von 1862 bis 1866* (Berlin, 1893); *Die nationale Rechtsidee von den Standen und das Preussische Dreiklassenwahlsystem* (*ibid.*, 1895); *Die verfassungsmässige Stellung des Preussischen Gesammtministeriums* (*ibid.*, 1895). See GIERKE, *Rudolph von Gneist, Gedächtnissrede* (Berlin, 1895), an In Memoriam address delivered in Berlin. (P. A. A.)

Gnesen (Polish, *Gniezno*), a town and archiepiscopal see of Prussia, province of Posen, 31 miles north-east from Posen by the railway to Thorn. It has new (Renaissance) administrative offices (1898) and a monument to the Emperor Frederick III. (1895); and linen and woollen weaving, and distilleries. Population (1885), 15,757; (1900), 21,661.

Goa, a territorial possession of Portugal, in India, bearing the official title of State of India. It embraces the three districts of Goa, Damão, and Diu, and stretches 60 miles along the Indian Ocean between 14° 53′ and 15° 44′ N. lat. The mean annual temperature at Panjim is 79·7° F., and at Satari 78·8°. Palms take the first place amongst the flora, especially the following species: *Cocus nucifera, Areca catechu, Caryota urens, Phœnix silvestris, Borassus flabelliformis, Cucifera thebaica* (date-palm), and *Corypha umbraculifera.* Other noteworthy vegetable products are the mango, three species of bananas, the bamboo, breadfruit tree, *sissó* (*Dalbergia sissoides*), teak (*Tectona grandis*), cutch or catechu (*Acacia catechu*), and *maura* (*Bacia latifolia*). Iron exists in various parts of the territory, and is extracted at Embarbacem and Astagraar. Agriculture is the principal occupation, and rice the principal crop; next comes the cocoanut, both for the nuts and for the juice (*sura*). Other cultivated products are betel-nut and bananas. Salt is very extensively prepared, and gives employment to nearly 2000 persons, who produce 23,200 tons of salt annually. Large quantities of native spirits are distilled from the palms. The average annual value of the imports for the three years 1894–96 was £216,800, and of the exports £114,800. In 1900 the imports through Marmagáo were valued at £53,160 and the exports at £25,700; and in addition there was a transit trade valued at £422,000. Goa imports textiles, cattle, wine, tea, rice, drugs, corn, potatoes and other edible roots, butter, sugar, oils, and tobacco; and exports cocoanuts, spices, fish, cashew nuts, bamboos, poultry, and timber. Trade is carried on almost entirely with Bombay, Madras, Kathiawar, and Portugal. A line of railway (51 miles) runs from Marmagáo to Castle Rock (on the Western Ghats). The area of the territory is estimated at 1400 square miles, and the population is 494,836 (1894), as compared with 420,868 (1881). The territory is ruled by a governor-general, and forms a separate ecclesiastical province of Portugal. Its capital is Nova Goa or Panjim, where there are a lyceum, normal school, seminary, technical school, and experimental agricultural station. For 1900–1901 the estimated revenue was £229,100, and expenditure £228,700.

See E. VILLAÇA, *Relatorio e Propostas de Lei*, Lisbon, 1899; LOPES MENDES, *A India Portuguesa*, Lisbon, 1886; and E. DE VASCONCELLOS, *As Colonias Portuguesas*, Lisbon, 1896–97. (E. DE V.)

Goalpara, a town and district of British India, in the Brahmaputra Valley division of Assam. The town (population, 5500) overlooks the Brahmaputra. It has declined in importance since the district headquarters were removed to Dhubri in 1879, and it suffered severely from the earthquake of 12th June 1897. The DISTRICT comprises an area of 3954 square miles. Its population in 1881 was 446,232, and in 1891 was 452,304, giving an average density of 114 persons per square mile. Classified according to religion, Hindus numbered 209,925; Mahommedans, 124,455; hill tribes, 116,112; Christians, 1632, of whom 51 were Europeans; "others," 180. In 1901 the population was 462,083, showing an increase of 2 per cent. The land revenue was Rs.1,25,383, the incidence of assessment being one pie per acre on the permanently settled portion, and R.1–6 on the rest; the number of police was 256; the number of boys at school in 1896–97 was 5896, being 16·6 per cent. of the male population of school-going age; the registered death-rate in 1897 was 49·65 per thousand. Tea cultivation does not flourish anywhere in the district. In 1897 there were three gardens, with 410 acres under tea, yielding 140,798 ℔. DHUBRI (population, 5000), the administrative headquarters of the district, stands on the Brahmaputra where that river takes its great bend south. It is the termination of the emigration road from North Bengal and also of the river steamers that connect with the North Bengal railway. In 1897, 66,952 coolie immigrants passed through.

Gobi or Shamo, the name which was formerly given to the whole of the steppes (dry prairies) and the stony or sandy deserts in Central Asia, extending in the form of a large crescent from the Pamirs in the south-west to the eastern corner of Transbaikalia, or Lake Dalai, in the north-east. In the north-west they are bounded by the highlands of the Eastern Tian-Shan and North-western Mongolia and by the Kentei escarpment, while along their south-eastern border the Kuen-lun, the Altyn-tagh, and the Nian-shan mountains separate them from the still higher and still more dreary plateaus of Northern Tibet, the Nian-shan joining by means of a succession of not yet explored plateaus and mountains the great Khingan border-ridge which separates the Gobi from Manchuria. Taken in this sense, the Gobi may be regarded as the lower terrace of the high plateau of East Asia. The western portions, however, of this immense region, which are watered by the Tarim, and belong geographically to the basin of Lob Nor (*nor* meaning lake), and politically to East Turkestan, may be conveniently considered as a separate region, which is known in Central Asia as the Taklamakan desert, and by geographers as the Tarim basin. The Gobi would thus be that part of the lower terrace which lies to the east of the 92nd degree of E. longitude (Greenwich), and would naturally be divided into two parts, the Western Gobi and the Eastern Gobi. (See MONGOLIA.)

Goch, a town of Prussia, in the Rhine province, 8 miles by rail south of Cleves. It manufactures brushes, plush goods, and cigars, and has oil-mills. In the Middle Ages it was the seat of a large trade in linen. Population (1900), 9101.

Godalming, a municipal borough and market-town in the Guildford parliamentary division of Surrey, England, on the Wey, 4 miles S.S.W. of Guildford by rail. Amongst its more recent buildings are a Masonic hall, the Victoria Hall, a home for epileptic women, and the technical institute and school of science and art. A drainage system costing £50,000 has been completed. Charterhouse School, originally founded in 1611, was transferred from London to Godalming in 1872. It stands within grounds 92 acres in extent, about half a mile north of Godalming, and consists of spacious buildings in Gothic style, with a chapel, library, and hall, besides boarding-houses, masters' houses, and sanatoria. The school has 34 masters and about 570 pupils. Area of municipal borough, 708 acres. Population (1901), 8748.

Godard, Benjamin Louis Paul (1849–1895), French composer, was born in Paris, 18th August 1849. He studied at the Conservatoire, and competed for the Prix de Rome without success in 1866 and 1867. He began by publishing a number of songs, many of which are charming, such as "Je ne veux pas d'autres choses," "Ninon," "Chanson de Florian," also a quantity of piano pieces, some chamber music, including several violin sonatas, a trio for piano and strings, a quartet for strings, a violin concerto, and a second work of the same kind entitled "Concerto Romantique." Godard's chance arrived in the year 1878, when with his dramatic cantata, *Le Tasse*, he shared with M. Théodore Dubois the honour of winning the musical competition instituted by the city of Paris. From that time until his death Godard composed a surprisingly large number of works, including four operas, *Pedro de Zalamea*, produced at Antwerp in 1884; *Jocelyn*, given in Paris at the Théâtre du Château d'Eau, in 1888; *Dante*, played at the Opéra Comique two years later; and *La Vivandière*, left unfinished and partly scored by another hand. This last work was heard at the Opéra Comique in 1895, and has been played in England by the Carl Rosa Opera Company. His other works include the "Symphonie Légendaire," "Symphonie Gothique," "Diane," and various orchestral works. Godard's productivity was enormous, and his compositions are, for this reason only, decidedly unequal. He was at his best in works of smaller dimensions, and has left many exquisite songs. Among his more ambitious works the "Symphonie Légendaire" may be singled out as being one of the most distinctive. He had a decided individuality, and his premature death at Cannes on 10th January 1895 was a loss to French art. (A. HE)

Godavari, a district of British India, in the north-east of the Madras Presidency, with an area of 7857 square miles. The population in 1891 was 2,078,782, being 264 persons per square mile for the hill-tracts alone, 42 per square mile, but rising to 407, for the rest of the district; in 1901 the population was 2,303,495, showing an increase of 11 per cent. The land revenue and rates (1898) were Rs.68,48,232, the incidence of assessment per acre being Rs.3–11–4 in *ryotwari* and R.0–13–3 in *zamindari* lands; the number of police was 1416. In 1897–98, out of a total cultivated area of 1,028,646 acres, 616,564 were irrigated from Government canals. The country has always been able to provide a large surplus for export. The principal crops are rice, millet, other food grains, pulse, oil-seeds, tobacco, sugar, and cotton. The cigars known in England as Lunkas are partly made from tobacco grown on *lankas* or islands in the river Godavari. The administrative headquarters are now at Cocanada, the chief seaport; but Rajahmundry, at the head of the delta, is the old capital. A large and increasing trade is conducted at Cocanada and Coringa, rice being there shipped to the Maldives, Mauritius, and Ceylon. At both these places rice-cleaning mills have been established. In 1897–98 the total sea-borne trade of the district was valued at Rs.2,07,82,027, of which just half was with foreign countries. The district is traversed by the main line of the East Coast railway, with a branch to Cocanada; the iron girder bridge of forty-two spans over the Godavari

river near Rajahmundry was opened in 1900. There is a Government college at Rajahmundry, with a training college attached, and an aided college at Cocanada. In 1896–97 there were altogether 1538 schools, attended by 50,945 pupils. There are thirteen printing-presses, issuing three English and three vernacular periodicals, and several libraries, reading-rooms, and literary institutes. The registered death-rate in 1897 was 22·8 per thousand.

Godesberg, a village of Prussia, in the Rhine province, Germany, on the left bank of the Rhine, 4 miles by rail south from Bonn. It is a favourite summer resort, with numerous villas belonging to the manufacturers and merchants of Cologne, Elberfeld, Crefeld, and other towns. There are three churches, including the Roman Catholic, built in the Gothic style in 1862, a famous hydropathic (1859), chalybeate springs (1864–65), a fine park (1892), and on a basalt peak (246 feet above the town) the ruins of Godesberg castle, built by the Archbishop of Cologne in the 13th and 14th centuries, and destroyed by the Elector of Bavaria in 1583. Population (1900), 8927.

Godhra, a town of British India, administrative headquarters of the Panch Mahals district of Bombay, and also of the Rewa Kantha political agency; situated in 22° 46′ N. lat. and 73° 40′ E. long., 52 miles north-east of Baroda. Population, 14,000. It is on the line from Anand to Rutlam, and has a Telang high school, and a printing-press issuing a vernacular newspaper.

Göding, the chief town of a government district in Southern Moravia, on the right bank of the river March, at this point forming the frontier between Austria and Hungary, and becoming navigable. The old imperial castle is the centre of the Moravian family estates of the Austrian reigning house. The manufactures comprise tobacco, white-lead, starch, and cloth. Population, half Czech (1890), 8482; (1900), 10,231.

Godkin, Edwin Lawrence (1831–1902), American author, was born of English parents in Moyne, County Wicklow, Ireland, 2nd October 1831, and graduated at Queen's College, Belfast, in 1851. In the Crimean war, from 1854 to 1856, he was correspondent of the London *Daily News*. In 1856 he made the United States his home, and was admitted to the bar in 1859, but continued his journalistic work. In 1865—partly because of a scheme on the part of several friends of the lately freed Africans to establish a newspaper to promote the interests of the coloured population—he was enabled to carry out a cherished plan to edit an American political and critical weekly somewhat on the lines of the London *Spectator*; and the *Nation* was started in New York, with Mr Godkin as its leading spirit. In 1881, with Carl Schurz and Horace White, he acquired control of the New York *Evening Post* (daily), and the *Nation* was thenceforward made up of matter appearing in the *Post*. He retired on account of ill-health in 1899. His principal work was done in advocacy of political independence, free trade, and civil service reform, which he defended with a satirical pen. From his articles in the *Nation* and other periodicals he gathered several volumes, of which the chief are *Reflections and Comments 1865–95*, and *Unforeseen Tendencies of Democracy* (1898). He died at Brixham, England, on 21st May 1902.

Gödöllö, a market town of Hungary, 23 miles distant from Budapest, in the county of Pest-Pilis-Solt-Kis-Kun, with 5885 inhabitants in 1900. The king's summer castle, which formerly belonged to the princes Grassalkovich, was, along with the beautiful domain, presented by the Hungarian nation to King Francis Joseph I. after the coronation in 1867. In its park there are a great number of stags and wild boars. Gödöllö is a favourite summer resort of the inhabitants of Budapest. In its vicinity is the famous place of pilgrimage Mária-Besnyö, with a fine Franciscan cloister, wherein lived Fessler, the Hungarian historiographer.

Gokcha (*Gök-chai*; Armenian, *Sevanga*; ancient *Göhkaruni*), the largest lake of Transcaucasia, government Erivan, Russia, 40° 9′ to 40° 38′ N. and 45° 1′ to 45° 40′ E. Its altitude is 6340 feet; it is of triangular shape, and measures from north-west to south-east 45 miles, its greatest width being 27 miles and its maximum depth 57 fathoms. Two peninsulas divide it into two parts, united by a strait 5 miles wide. It lies on a high plateau, surrounded by 12,000 feet of high, barren mountains of volcanic origin, and receives twenty-eight mountain rivers, which mostly dry up in summer. Its outflow is the Zanga, left bank tributary of the Araks (*Araxes*); it never freezes, and its level undergoes periodical oscillations. It contains four species of *Salmonidæ*, and two of the *Cyprinidæ*, which are only met with in the drainage area of this lake.

Golcar, a township in the Colne Valley parliamentary division of the West Riding of Yorkshire, England, 3 miles W.S.W. of Huddersfield by rail. It stands on the Colne Valley canal. The chief industry is the manufacture of fancy woollen goods. Area of urban district, 1593 acres. Population (1881), 7653; (1901), 9260.

Gold.—The nature and history of this metal were fully dealt with in the ninth edition of the *Ency. Brit.*, and the quantities produced in various countries for years ranging from 1875 to 1879 were also given. For many years afterwards the annual production continued to decrease, the average production of the five years 1881–85 being the smallest since the Australian and Californian mines began to be worked in 1848–49. It was not until after 1885 that the annual output of the world began to expand. Of the total production in 1876 almost the whole was derived from the United States, Australasia, and Russia. Since then the proportion furnished by these countries has been greatly lowered by the appearance of South Africa, Canada, India, and China among the gold-producers. The increase of production has not been uniform, the greater part having occurred most notably since 1895. Among the regions not previously important as gold-producers which now contribute to the annual output, the most remarkable are the goldfields of South Africa (Transvaal), which were discovered in 1885. India likewise has been added to the list, its active production having begun at about the same time as that of South Africa. The average annual product of India for the period 1886 to 1899 inclusive was £698,208, and its present annual product averages from 450,000 to 500,000 ounces, or about £1,900,000, obtained almost wholly from the free-milling quartz veins of the Colar goldfields in Mysore, Southern India. Canada, too, has assumed an important rank, having contributed in 1900 £5,583,300. This great increase was due to the development of the goldfields of the North-Western Territory, especially British Columbia. From the district of Yukon (Klondike, &c.) £2,800,000 were obtained in 1899, wholly from alluvial workings, but the progress made since has been slower than was expected by sanguine people. It is, however, probable that the North-Western Territory will continue to yield gold in important quantities for

some time to come, though it is impossible to make any estimate of the future annual output.

The output of the United States increased from 1,678,612 ounces in 1881 to 3,829,897 ounces in 1900. The provisional estimate of the director of the United States Mint for 1901 was for a value of £16,043,800, against £15,864,000 in 1900. This increase was chiefly due to the exploitation of new goldfields. The fall in the price of silver stimulated the discovery and development of gold deposits, and many States formerly regarded as characteristically silver districts have become important as gold producers. Colorado is a case in point, its output having increased during the period under review from about £600,000 to £6,065,000 in 1900. Somewhat more than one-half of the Colorado gold is obtained from the Cripple Creek district. Other States also showed a largely augmented product. On the other hand, the output of California, which was producing over £3,000,000 per annum in 1876, has fallen off, the average annual output from 1876 to 1900 being £2,800,000. This decrease was largely caused by the practical suspension for many years of the hydraulic mining operations, in preparation for which millions of dollars had been expended in deep tunnels, flumes, &c., and the active continuance of which might have been expected to yield some £2,000,000 of gold annually. This interruption, due to the practical prohibition of the industry by the United States courts, on the ground that it was injuring, through the deposit of tailings, agricultural lands and navigable streams, was lessened, though not entirely removed, by compromises and regulations which permit, under certain restrictions, the renewed exploitation of the ancient river-beds by the hydraulic method. On the other hand, the progressive reduction of mining and metallurgical costs effected by improved transportation and machinery, and the use of high explosives, compressed air, electric-power transmission, &c., resulted in California (as elsewhere) in a notable revival of deep mining. This was especially the case on the "Mother Lode," where highly promising results were obtained. Not only is vein-material, formerly regarded as unremunerative, now extracted at a profit, but in many instances increased gold-values have been encountered below zones of relative barrenness, and operators have been encouraged to make costly preparations for really deep mining—more than 3000 feet below the surface. The gold product of California, therefore, may be fairly expected to maintain itself, and, indeed, to show an advance. Alaska first appeared in the list of gold-producing countries in 1880, and gradually increased its annual output until the year 1900, when it yielded 375,922 ounces. The Alaska gold is derived at present almost wholly from the large low-grade quartz mines of Douglas Island. But in 1899 another important district was discovered at Cape Nome, on the north-western coast. The result of a few months' working during that year was more than £500,000 of gold, and a very much larger annual output may reasonably be anticipated in the future. The gold occurs in alluvial deposits designated as gulch-, bar-, beach-, tundra-, and bench-placers. The tundra is a coastal plain, swampy, and covered with undergrowth and underlaid by gravel. The most interesting and, thus far, the most productive are the beach deposits, similar to those on the coast of Northern California. These occur in a strip of comparatively fine gravel and sand, 150 yards wide, extending along the shore. The gold is found in stratified layers, with "ruby" and black sand. The "ruby" sand consists chiefly of fine garnets and magnetites, with a few rose-quartz grains. As yet the relative importance of the other placers has not been determined. Further exploration of the interior will probably result in the discovery of additional gold districts. Mexico, from a gold production of £200,000 in 1891, advanced to about £1,881,800 in 1900. Of this increase, a considerable part was derived from gold-quartz mining, though much was also obtained as a by-product in the working of the ores of other metals. The product of Colombia, Venezuela, the Guianas, Brazil, Uruguay, Argentina, Chile, Bolivia, Peru, and Ecuador amounted in 1900 to £2,481,300, of which Colombia and the Guianas supplied more than one-half.

In 1876 Australasia produced £7,364,120, of which Victoria contributed £3,984,349. The annual output of Victoria declined until the year 1892, when it began to increase rapidly, but not to its former level, the value for 1900 having been £3,142,400. There has been an important increase in Queensland, which from £1,696,304 in 1876 advanced to £3,248,000 in 1899. There has been no increase and, indeed, no large fluctuation until quite recently in the output of New Zealand, which averaged £1,054,000 per annum from 1876 to 1898, but the production of the two years 1899 and 1900 rose to £1,472,600 and £1,394,520 respectively. By far the most important addition to the Australasian product has come from West Australia, which began its production in 1887—about the time of the inception of mining at Witwatersrand ("the Rand") in South Africa —and by continuous increase, which assumed large proportions towards the close of the 19th century, was 1,643,873 ounces, or £6,426,000, in 1899 and 1,580,949 ounces, or £6,179,000, in 1900. For 1901 the yield was returned at 1,869,459 ounces, subject to revision.

Undoubtedly the greatest of the gold discoveries made in the latter half of the 19th century was that of the Witwatersrand district in the Transvaal. By reason of its unusual geological character and great economic importance this district deserves a more extended description. The gold occurs in conglomerate beds, locally known as "banket." There are several series of parallel beds, interstratified with quartzite and schist, the most important being the "main reef" series. The gold in this conglomerate reef is partly of detrital origin and partly of the genetic character of ordinary vein-gold. The formation is noted for its regularity as regards both the thickness and the gold-tenor of the ore-bearing reefs, in which respect it is unparalleled in the geology of the auriferous formations. The gold carries, on an average, £2 per ton, and is worked by ordinary methods of gold-mining, stamp-milling, and cyaniding. In 1899, 5762 stamps were in operation, crushing 7,331,446 tons of ore, and yielding £15,134,000, equivalent to 25·5 per cent. of the world's production. Of this, 80 per cent. came from within 12 miles of Johannesburg. After September 1899 operations were suspended, almost entirely owing to the war, but on 2nd May 1901 they recommenced, and some progress had been made by January 1902 towards placing the industry in its former position. The total for the eight months ended 31st December 1901 was 238,991 ounces. So certain is the ore-bearing formation that engineers in estimating its auriferous contents feel justified in assuming, as a factor in their calculations, a vertical extension limited only by the lowest depths at which mining is feasible. On such a basis they arrived at more than £600,000,000 as the available gold contained in the Witwatersrand conglomerates. At the rate of exploitation in 1899 this amount would be extracted in about thirty years, but this period will, it is assumed, be diminished by increase in the magnitude of the exploitations. Deposits similar to the Witwatersrand banket occur in Zululand, and also on the Gold Coast of

Africa; but these localities have been worked to a small extent only. Considerable mining developments are being made in Rhodesia, the country lying north of the Transvaal, where gold occurs in well-defined quartz-veins, and there is unquestionable evidence of extensive ancient workings. The economic importance of the region generally has not been fully proved, mining by modern methods being still in its infancy there. Rhodesia produced 91,940 ounces in 1900 and 172,061 ounces in 1901, in spite of the South African war.

The gold production of Russia during the period under review was remarkably constant, averaging £4,899,262 per annum; the gold is derived chiefly from placer workings in Siberia. Gold discoveries have been made in Eastern and Southern Siberia, from which an important output may be expected. The completion of the trans-Siberian railway will stimulate mining.

The gold production of China was estimated for 1899 at £1,328,238 and for 1900 at £860,000, showing approximately the average annual production from 1883 to 1900 inclusive. Considerable increase will doubtless attend the development of the empire.

Table of the Quantities of Gold produced in the Undermentioned Countries in the Years named (*in ounces*).

Year.	Australasia.	Africa.	Canada.	India.	Mexico.	Russia.	United States.	Other Countries.	Total.
1881	1,475,161	...	52,483	...	41,545	1,181,853	1,678,612	547,326	4,976,980
1882	1,438,067	...	52,000	..	45,289	1,154,613	1,572,187	563,638	4,825,794
1883	1,333,849	...	46,150	...	46,229	1,132,219	1,451,250	849,805	4,859,502
1884	1,352,761	...	46,000	...	57,227	1,055,642	1,489,950	901,309	4,902,889
1885	1,309,804	...	53,987	...	46,941	1,225,738	1,538,325	827,789	5,002,584

[1] The Chamber of Mines of the late South African Republic in its report for the year ended 30th December 1899 gives a table from which it appears that the total output of 1887, 1888, and 1889 was 642,804 ounces, of which 42,000 ounces represent "estimated unrecorded production" for those years. The figures given above show a total of 635,043 ounces, and it is unnecessary to alter them.

[2] Incomplete. [3] Estimated. [4] Partly estimated.

Metallurgy.—During the period 1875–1900 no radical changes were made in the amalgamation of gold ores, nor was there any great improvement in crushing the ores. By increased weight of stamps, and by the use of "self-feeders," the capacity of the batteries has been considerably enlarged. Where conditions are specially favourable, other classes of pulverizing machines are sometimes used. The cyanide process is the only radically new departure in gold metallurgy proper. It is mainly used in the treatment of battery-tailings, and has been found of advantage. It consists essentially in (1) the solution of the gold in cyanide of potassium; (2) the precipitation of the dissolved gold by means of zinc (M'Arthur Forrest process), or by electricity (Siemens and Halske, and other modifications); and (3) the fusion and casting into ingots of the precipitated gold. Gold ores, other than tailings, are occasionally cyanided in the raw state, or after the preliminary roasting. The process is applicable also to the recovery of gold from certain classes of auriferous pyrites. To render the process economically successful the gold must be in a fine state of division, and the ores must not carry too great a percentage of deleterious substances, the presence of which necessitates an excessive consumption of cyanide and of zinc. Preliminary roasting may extend the application of the process to the treatment of base ores. Cyaniding has in many cases superseded the chlorination process, though in America the latter is still often preferred where a preliminary roasting is required. About 33 per cent. of the gold produced in the Witwatersrand district is extracted by the cyanide process, to which the gold ores of that district are exceptionally adapted. When conducted on a large scale the entire metallurgical treatment of the Witwatersrand ores, *i.e.*, the crushing and amalgamation of the ore and the cyaniding of the tailings and slimes, costs about six shillings per ton, the cost of cyaniding being about two to four shillings per ton. From 90 to 95 per cent. of the assay value of the ore is recovered by these combined processes in the Witwatersrand district.

In the extraction of gold from concentrates by the chlorination process the use of sulphur dioxide or hydrogen sulphide as precipitants is more general now than formerly, these reagents being deemed preferable to ferrous sulphate when time is of importance. Barrel chlorination has to some extent taken the place of chlorination in vats. The chemical reactions are the same in both, but in the barrel process the agitation of the pulp by revolution, and the generation of chlorine by chemical action throughout the mass, facilitates and hastens the solution of the gold. The most noteworthy improvement in refining is the Wohlevill electrolytic process, which has been successfully employed in the two principal gold refineries of Germany. It is chiefly valuable in cases where the gold is alloyed with a small amount of platinum.

Though revolutionary inventions or improvements in the direct metallurgy of gold have been few, the cost of producing gold has been greatly reduced by causes which have affected other mining and metallurgical industries as well. Among these are to be mentioned the immense increase in the transmission and use of mechanical power, including devices for the handling of large quantities of material with a minimum of manual labour; the use of

high explosives in mining; and especially the immense extension of metallurgical enterprises, based on the reduction of lead or copper ores, in which both gold and silver are obtained practically as by-products. It often happens, for instance, in the United States that the miner of a gold-bearing ore desirable to smelters by reason of its other ingredients can realize 90 to 95 per cent. of its gold value without payment of any smelting charges for that metal. These commercial conditions often act as a competitive limit upon such processes as stamp-milling, amalgamation, chlorination, and cyaniding, the whole cost of which must be assessed upon the gold produced.

In working auriferous river-beds, dredges have been used with considerable success in certain parts of New Zealand and on the Pacific slope in America. The field for such operations is, of course, limited. The dredges used in California are almost exclusively of the endless-chain bucket or steam-shovel pattern. Some dredges have a capacity, under favourable conditions, of 2000 cubic yards of gravel daily, which they handle at a cost of from five to ten cents per cubic yard.

Industrial Consumption.—It is estimated by the director of the United States Mint (*Report upon the Production of the Precious Metals in the United States during the calendar Year* 1899, p. 50) that the world's industrial consumption of gold for the year 1898 amounted to about £15,000,000, of which about £10,750,000, or about 71 per cent., was taken by the United States, Germany, France, and Great Britain. (J. H. H*.)

Gold Coast.—The name "Gold Coast" denotes geographically that portion of the Guinea coast which extends from Asinie upon the west to the river Volta on the east, but it is now generally restricted to the political colony and protectorate of the Gold Coast, belonging to Great Britain. This extends from about 3 degrees west longitude to about 1·14 degrees east longitude, the length of the coast-line being about 350 miles. It is bounded on the west by the French colony of the Ivory Coast, and on the east by German Togoland. On the north the nominal boundary, as against the nominal boundary of the French Sudan, extends to the 11th degree of north latitude, but at the present time the actual extent of the colony and protectorate is very much more circumscribed. Inland the breadth of the protectorate, excluding Ashanti and the Northern Territories, varies considerably, but its breadth appears nowhere greatly to exceed 200 miles, and the average breadth is, for the most part, not much more than 50 miles. The total area, including all the hinterland allotted by European conventions, has been estimated at 74,500 square miles; excluding Ashanti and the Northern Territories, it is about 40,000 square miles, with a population of about 1½ million. The Northern Territories, up to November 1899, were separated from Togoland by a Neutral Zone. The territory thus described was then, however, apportioned between Great Britain and Germany. The river Daka was fixed as the boundary as far north as 9° N. lat., whence it was arranged that the frontier should be so delimited that Gambaga and the territories of Mamprusi fell to the Gold Coast, and Yendi and the territories of Chakosi to Togoland.

The Gold Coast proper possesses no harbours, and bars of sand block the mouths of the rivers. Of the towns, Axim is the port of the gold-mines of Wassau and the outlet of a large timber trade; Elmina has a population of over 11,000, Cape Coast Castle about 12,000, and Accra, the capital, about 20,000. Saltpond, between Cape Coast Castle and Accra, is worthy of notice as the principal centre of the palm oil industry.

For many years the Gold Coast played an important part in the struggle of the various nations for colonial supremacy. Portugal here took the lead, founding San Gorge la Mina (Elmina) in 1470. The English appeared upon the scene in the middle of the 16th century, and were soon followed by the French. More dangerous rivals arose in the shape of the Dutch, who from the end of the 16th century sought to oust the Portuguese from the Gold Coast, and in whose favour the Portuguese did finally withdraw in 1642, in return for the withdrawal on the part of the Dutch of claims to Brazil. Inasmuch as the Dutch did not interfere with the country outside their immediate posts, British and other European traders were able to establish settlements along the coast. The troubles with the powerful native kings of Ashanti, in which the British colony became involved when its importance as a slave-trading centre came to an end, and which latterly were largely due to the acquisition by the British of the territory held by other European Powers, finally culminated (as was shown in the ninth edition under ASHANTI) in the capture of Kumasi in 1874, an event which involved consequences unwished for by the home Government. It was followed by the defection of outlying provinces, some of which became absorbed in the British protectorate. Hostile chiefs were pursued by the Ashanti king into British territory, and a state of unrest was generally prevalent. Remedial measures proved impossible against the obstinacy of King Prempeh, and it became apparent that a state of things had been brought about which necessitated annexation (see below). Ashanti became British in 1896, and in 1899 the governor was able to report that, "taking it as a whole, the country seemed contented and prosperous, a pauper being unknown." An organized rebellion in the following year, which at one time seemed likely to involve very grave consequences, showed that there were still serious troubles to be surmounted before the Ashantis settled down under British rule.

Ashanti.

The Gold Coast is a Crown colony, with a governor, executive council, and legislative council. The executive council consists of five members; the legislative of the same, with the addition of the chief justice and three nominated unofficial members. The supreme court consists of a chief justice and three puisne judges. There are district commissioners, and in the protectorate native chiefs have a limited jurisdiction. There are also travelling commissioners for native affairs, a British resident for Ashanti, and a commissioner for the Northern Territories, as the territories behind the Gold Coast and north of Ashanti are now designated.

The Gold Coast constabulary includes both a military and civil police, the former being mainly recruited from the Hausas.

The following are the figures of the revenue and expenditure during 1896–1900 :—

Year.	Revenue.	Expenditure.
1896	£237,460	£282,277
1897	233,179	401,692
1898	258,822	377,976
1899	422,796	309,656
1900	383,283	272.203

The large deficits in 1897 and 1898 were mainly due to punitive expeditions, £147,587 of the expenditure in 1897 being entirely on account of the Ashanti campaign. The revenue is mainly raised by customs duties. There is still no standing public debt, but the colony is responsible for advances to the amount of £435,448, in great part for the Sekundi-Tarkwa railway.

The trade of the Gold Coast has latterly greatly increased, as the following table shows :—

Year.	Imports.	Exports.
1896	£778,009	£792,111
1897	784,188	857,793
1898	960,336	992,998
1899	1,152,478	1,111,738
1900	1,294,963	885,445

Rubber represents over 50 per cent. in value of the total exports, and palm oil and kernels nearly 20 per cent. Next in importance to these comes gold dust. Cotton goods are the principal import.

Of the potential wealth of the country there can be no question. "Rich in gold, in valuable timber, in soil which will produce almost any commodity of trade value," the great difficulty in the way of

its development is the difficulty of access to the interior. The colony west of Accra is in the forest belt of Africa, and the rivers, though numerous, abound in rocks and rapids. Although hitherto the output of gold has not been very great, it is believed that with the opening of a railway the gold industry is capable of great developments. The export of gold was valued at £86,186 in 1896, but at only £38,007 in 1900. There are said to be twenty miles of banket reef gold in Wassau, Ashanti, and Kwahu, very similar to that in the Transvaal. A railway, from Sekundi, on the coast, to the mining district of Tarkwa, has been constructed, and railway surveys have also been made in various directions. Rubber, which at present remains the staple product, is shipped from Cape Coast Castle, Accra, and Quitta. A large amount of rubber comes from Ashanti, and it is estimated that the output could be easily trebled were the transport rendered cheaper. Palm oil and palm kernels come mainly from the districts behind Saltpond, and from the districts of Aquassim and Crobol. Valuable timbers abound in the hinterland. There is a good road from Cape Coast Castle to Prahsu, and from Accra to Aburi, and a road has been constructed for about fifty miles in the Northern Territories. There are about 700 miles of telegraph open. But whatever the improvement in the means of transport, the unhealthiness of the climate must always be a retarding influence upon the development of the Gold Coast. There are at present only about 200 European inhabitants, and the number will probably not greatly increase.

The rainfall averages at Accra 30 inches in the year, but at other places the fall is much greater. There are two wet seasons, April to July, and October and November. From December to March the dry Harmattan wind blows.

Under the agency of the Basel, Wesleyan, and Roman Catholic missionary societies elementary education is spreading. There are Government schools at Accra, Cape Coast Castle, and Insuaim, and the total number of schools, assisted and not assisted, was, in 1898, 208. Very little has yet been done in the way of secondary education.

Ashanti Expeditions, 1895–1900.

The treaty arranged between the British authorities and the Ashantis after the expedition of 1873–74 (see *Ency. Brit.*, 9th ed., ii. 682) had remained practically a dead letter. The road from Kumasi to Cape Coast Castle had not been kept open to trade. The indemnity had only been paid in part. Human sacrifices continued. Under King Prempeh the Ashanti power became more and more a disturbing influence in the hinterland of the Gold Coast colony, and an obstacle to trade and civilization. It was impossible to permit the reign of murder within a short distance of the British frontier, and demands made for the complete fulfilment of the terms of the treaty produced no result. The king declined to treat with the governor of the Gold Coast, and despatched informal agents to England, whom the Secretary of State refused to receive. To put an end to the misgovernment and barbarities carried on at Kumasi, and to establish law, order, and security for trade, an expedition was at length decided upon. The force, placed under Colonel Sir Francis Scott, consisted of the 2nd West Yorkshire Regiment, a "special service corps," made up of detachments from various regiments in the United Kingdom, under specially selected officers; the 2nd West India Regiment, and the Gold Coast and Lagos Hausas. The composition of the special service corps was much criticized at the time; but as it was not called upon for fighting purposes, no inferences as to its efficiency are possible. The details of the expedition were carefully organized. Before the arrival of the staff and contingent from England the native forces were employed in improving the road from Cape Coast Castle to Prahsu (70 miles), and in establishing road stations to serve as standing camps for the troops. About 12,000 carriers were collected, the load allotted to each being 50 ℔. In addition, a force of native scouts, which ultimately reached a total of 860 men, was organized in eighteen companies and partly armed with Snider rifles to cover the advance of the main column and to improve the road. The king of Bekwai having asked for British protection, a small force was pressed forward and occupied this native town, about 25 miles from Kumasi, on 4th January 1896. The advance continued, and at Ordahsu a mission arrived from King Prempeh offering unconditional submission. On 17th January Kumasi was occupied, and Colonel Sir F. Scott received the king. Effective measures were taken to prevent his escape, and on the 20th Prempeh made submission to Mr Maxwell, the governor of Cape Coast, in native fashion. The king, with the queen mother and the principal chiefs, was then arrested and taken as a prisoner to Cape Coast Castle, where they were embarked on board H.M.S. *Racoon* for Elmina. The fetish buildings at Bantama were burned, and on 22nd January Bokro, a village 5 miles from Kumasi, and Maheer, the king's summer palace, were visited by the native scouts and found deserted. On the same day, leaving the Hausas at Kumasi, the expedition began the return march of 150 miles to Cape Coast Castle. The complete success of the expedition was due to the excellent organization of the supply and transport services, while the promptitude with which the operations were carried out probably accounts in great measure for the absence of resistance. Although no fighting occurred, a heavy strain was thrown upon all ranks, and fever claimed many victims, among whom was Prince Henry of Battenberg, who had volunteered for the post of military secretary to Colonel Sir F. Scott. (G. S. C.)

Expedition of 1895-96.

Expedition of 1900.

In 1900, after four years of peace, a serious rebellion broke out in Ashanti. The tribes involved were the Kumasis, Adansis, and Kokofus; the other tribes of the Ashanti confederation remained loyal. The rebels were, however, able to command a force reported to number 40,000. On 28th March the governor of the Gold Coast, Sir F. Hodgson, in a public palaver at Kumasi, announced that the Ashanti chiefs would have to pay the British Government 4000 ounces of gold yearly, and he reproached the chiefs with not having brought to him the Golden Stool—the emblem of sovereignty among the Ashantis—which the Kumasis had kept hidden since 1896. Three days afterwards the Kumasi warriors attacked a party of Hausas sent with the chief object of discovering the Golden Stool. (In the previous January a secret attempt to seize the Stool had failed.) The Kumasis, who were longing to wipe out the dishonour of having let Prempeh be deported without fighting, next threatened the fort of Kumasi. Mr Ramseyer and the other Basel missionaries, and Sir F. and Lady Hodgson, took refuge in the fort, and reinforcements were urgently asked for. On 18th April 100 Gold Coast constabulary arrived. On the 29th the Kumasis attacked in force, but were repulsed. The same day a party of 250 Lagos constabulary reached Kumasi. They had fought their way up, and came in with little ammunition. On 15th May Major Morris arrived from the British territory north of Ashanti, also with 250 men. The garrison now numbered 700. The 29 Europeans in the fort included four women. Outside the fort were gathered 3000 native refugees. Famine and disease soon began to tell their tale. Sir F. Hodgson sent out a message on 4th June (it reached the relieving force on 12th June), saying that they could only hold out to 11th June. However, it was not till 23rd June that the governor and all the Europeans save three, together with

600 Hausas of all ranks, sallied out of the fort. Avoiding the main road, held by the enemy in force, they attacked a weakly held stockade, and succeeded in cutting their way through, with a loss of two British officers mortally wounded, 39 Hausas killed, and double that number wounded or missing. The governor's party reached Cape Coast Castle safely on 10th July.

A force of 100 Hausas, with three white men (Captain Bishop, Mr Ralph, and Dr Hay), was left behind in Kumasi fort with rations to last three weeks. Meantime a relief expedition had been organized at the Gold Coast by Lieut.-Colonel Willcocks. This officer reached Cape Coast Castle from Nigeria on 26th May. The difficulties before him were appalling. Carriers could scarcely be obtained, there were no local food supplies, the rainy season was at its height, all the roads were deep mire, the bush was almost impenetrable, and the enemy were both brave and cunning, fighting behind concealed stockades. It was not until the 2nd of July that Colonel Willcocks was able to advance to Fumsu. On the next day he heard of the escape of the governor and of the straits of the garrison left at Kumasi. He determined to relieve the fort in time, and on the 9th of July reached Bekwai, the king of which place had remained loyal. Making his final dispositions, the colonel spread a report that on the 13th he would attack Kokofu, east of Bekwai, and this drew off several thousands of the enemy from Kumasi. After feinting to attack Kokofu, Colonel Willcocks suddenly marched west. There was smart fighting on the 14th, and at 4.30 P.M. on the 15th, after a march since daybreak through roads "in indescribably bad condition," the main rebel stockade was encountered. It was carried at the point of the bayonet by the Yoruba troops, who proved themselves fully equal to the Hausas. "The charge could not have been beaten in *élan* by any soldiers." Kumasi was entered the same evening, a bugler of the war-worn garrison of the fort sounding "the general salute" as the relieving column came in view. Most of the defenders were too weak to stand. Outside the fort nothing was to be seen but burnt-down houses and putrid bodies. The relieving force that marched into Kumasi consisted of 1000 fighting men (all West Africans), with 60 white men, two 75-millimetre guns, four seven-pounder guns, and six Maxims.

Kumasi relieved, there remained the task of crushing the rebellion. Colonel Willcocks's force was increased by Yaos from Central Africa and by Sikhs to a total of 3368 natives, with 134 British officers, and 35 British non-commissioned officers. In addition there were Ashanti levies. On the 30th of September the Kumasis were completely beaten at Obassa. Thereafter many of the rebel chiefs surrendered, and the only two remaining in the field were captured on 28th December. Thus 1901 opened with peace restored. The total number of casualties during the campaign (including those who died of disease) was 1007. Nine British officers were killed in action, 43 were wounded, and six died of disease. The commander, Lieut.-Colonel Willcocks, was promoted colonel, created a K.C.M.G., was mentioned in the King's speech at the opening of Parliament in 1901, and received the freedom of the City of London, with a sword of honour. Sir F. Hodgson was appointed Governor of Barbados, and Major Nathan took his place on the Gold Coast. By an Order in Council, dated 26th September 1901, Ashanti was formally annexed to the British dominions.

(F. R. C.)

Goldie, Sir George Dashwood Taubman (1846- ——), British colonial administrator, was born on 20th May 1846 at the Nunnery in the Isle of Man, being the youngest son of Lieut.-Colonel John Taubman Goldie-Taubman, Speaker of the House of Keys, by his second wife Caroline, daughter of John E. Hoveden of Hemingford, Cambridgeshire. Sir George resumed his paternal name, Goldie, by royal licence in 1887. He was educated at the Royal Military Academy, Woolwich, and for a few months held a commission in the Royal Engineers. He travelled in all parts of Africa, gaining an extensive knowledge of the continent, and first visited the country of the Niger in 1877. He was impressed by the advantage to be gained by uniting all British interests in that region, and in 1879 succeeded in promoting the United African Company. In 1881 a charter was sought from Government, the capital of the company was raised from £125,000 to £1,000,000, and it was renamed the National African Company. The French traders who established stations on the Lower Niger rendered it difficult to obtain any territorial rights in the country, but in 1884 they were bought out, prior to the meeting of the Berlin Conference, where Taubman was present as an expert on matters relating to the Niger. Through Joseph Thompson, the explorer of Masailand, treaties were made with over three hundred native chiefs, and in July 1886 a charter was at length granted, the National African Company becoming the Royal Niger Company, with Lord Aberdare as governor and Taubman as vice-governor. In 1887 Goldie was created K.C.M.G., and in 1897 he took part in the successful expedition of the company against the Mahommedan states of Nupé and Ilorin. In the following year the differences with France in regard to the frontier line became acute, and compelled the intervention of the British Government. It was evidently impossible for a commercial association to hold its own against the State-supported protectorates of France and Germany, and in consequence, on 1st January 1900, the Royal Niger Company transferred its territories to the British Government for the sum of £865,000. The ceded territory was styled the protectorate of Northern Nigeria, and placed under the governorship of Colonel Lugard. Goldie was created a privy councillor in 1898. He is honorary D.C.L. of Oxford University (1897) and honorary LL.D. of Cambridge (1897). He married in 1870 Matilda Catherine (died 1898), daughter of John William Elliott of Wakefield.

Goldingen (Lettish, *Kuldiga*), a district town of Russia, government of Courland, 40 miles S.E. of Windau, on Windau river. It has woollen mills, needle and match factories, as well as a gymnasium for boys of the Courland nobility, and a college for teachers. Population (1897), 9733.

Goldmark, Karl (1832- ——), Hungarian composer, was born at Keszthely-am-Plattensee, in Hungary, on 18th May 1832. His father, a poor cantor in the local Jewish synagogue, was unable to assist to any extent financially in the development of his son's talents. Yet in the household much music was made, and on a cheap violin and home-made flute, constructed by Goldmark himself from reeds cut from the river-bank, the future composer gave rein to his musical ideas. This was helped on by the village schoolmaster, by whose aid he was able to enter the music-school of the Oedenburger Verein. Here he remained but a short time, his success at a school concert finally determining his parents to allow him to devote himself entirely to music. In 1844, then, he went to Vienna, where Jansa took up his cause and eventually obtained for him admission to the conservatorium. For two years Goldmark worked under Jansa at the violin, and on the outbreak of the revolution, after studying all the orchestral instruments he obtained an engagement in

the orchestra at Raab. There, on the capitulation of Raab, he was to have been shot for a spy, and was only saved at the eleventh hour by the happy arrival of a former colleague. In 1850 Goldmark left Raab for Vienna, where from his friend Mittrich he obtained his first real knowledge of the classics. There, too, he devoted himself to composition, and in the course of a short time he produced a veritable mountain of music. In 1857, while suffering severely from the prevalent Mendelssohn fever, Goldmark, who was then engaged in the Karl-theater band, gave a concert of his own works with such success that his first quartet attracted very general attention. Then followed the "Sakuntala" and "Penthesilea" overtures, in which Goldmark showed how Wagner's influence had cured his aforesaid fever, and the delightful "Ländliche Hochzeit" symphony, which carried his fame abroad. His reputation was now made, and very largely increased by the production at Vienna in 1875 of his first and best opera, *Die Königin von Saba.* Over this opera Goldmark spent seven years. Its popularity is still almost as great as ever. It was followed in November 1886, also at Vienna, by *Merlin*, much of which has been rewritten since then. A third opera, a version of Dickens's *Cricket on the Hearth*, was given by the Royal Carl Rosa Company in London in 1900. Goldmark's chamber music has not made much lasting impression in England, but the overtures "Im Frühling," "Prometheus Bound," and "Sapho" were given fairly constantly some years ago. In the realms of absolute music Goldmark is often dull. A "programme" seems essential to him. In opera he is most certainly at his best, and as an orchestral colourist he ranks among the very highest.

Goldsboro, capital of Wayne county, North Carolina, U.S.A., on the Neuse river, at an altitude of 110 feet. It is on the Atlanta and North Carolina, the Atlantic Coast, and the Southern railways. Population, (1880), 3286; (1890), 4017; (1900), 5877, of whom 76 were foreign-born and 2520 negroes.

Goldschmidt, Madame. See Lind, Jenny.

Golf.—In 1880 the man who travelled about England with a set of golf clubs was an object of some astonishment, almost of alarm, to his fellow-travellers. In those days the commonest of questions in regard to the game was, "You have to be a fine rider, do you not, to play golf?" so confounded was it in the popular mind with the game of polo. At Blackheath a few Scotsmen resident in London had long played golf. In 1864 the Royal North Devon Club was formed at Westward Ho, and this was the first of the seaside links discovered and laid out for golf in England. In 1869 the Royal Liverpool Club established itself in possession of the second English course of this quality at Hoylake, in Cheshire. A golf club was formed in connexion with the London Scottish Volunteers corps, which had its house on the Putney end of Wimbledon Common on Putney Heath; and, after making so much of a start, the progress of the game was slow, though steady, for many years. A few more clubs were formed; the numbers of golfers grew; but it could not be said that the game was yet in any sense popular in England. All at once, for no very obvious reason, the qualities of the ancient Scottish game seemed to strike home, and from that moment its popularity has been wonderfully and increasingly great. The English links that have most risen in favour during recent years is the fine course of the St George's Golf Club, near Sandwich, on the coast of Kent. It is a course that has two chief merits—the primary one of excellence for golf, and the secondary one of accessibility. To the London golfer it was the first course of the first class that was reasonably accessible, and the fact made something like an epoch in English golf. A very considerable increase, it is true, in the number of English golfers and English golf clubs had taken place before the discovery for golfing purposes of the links at Sandwich. Already there was a chain of links all round the coast, besides numerous inland courses; but since 1890 their increase has been extraordinary, so that there are now not much fewer than 1000 golf clubs in Great Britain and Ireland. To compute the average membership of these clubs is very difficult. There is not a little overlapping, in the sense that a member of one club will often be a member of several others; but probably the average may be placed at something like 200 members for each club. The immense amount of golf-playing that this denotes, the large industry in the making of clubs and balls, in the upkeep of links, in the actual work of club-carrying by the caddies, and in the instruction given by the professional class, is obvious. Golf has taken a strong hold on the affections of the people in all parts of Ireland, and the fashion for golf in England has reacted strongly on Scotland itself, the ancient home of the game, where since 1880 golfers have probably increased in the ratio of twenty to one. Besides the industry that such a growth of the game denotes in the branches immediately connected with it, as mentioned above, there is to be taken into further account the visiting population that it brings to all lodging-houses and hotels within reach of a tolerable golf links, so that many a fishing village has risen into a moderate watering-place by virtue of no other attractions than those which are offered by its golf course. Therefore to the Briton golf has developed from something of which he had a vague idea—as of "curling"—to something in the nature of an important business, a business that can make towns and has a considerable effect on the receipts of railway companies.

Progress of the game.

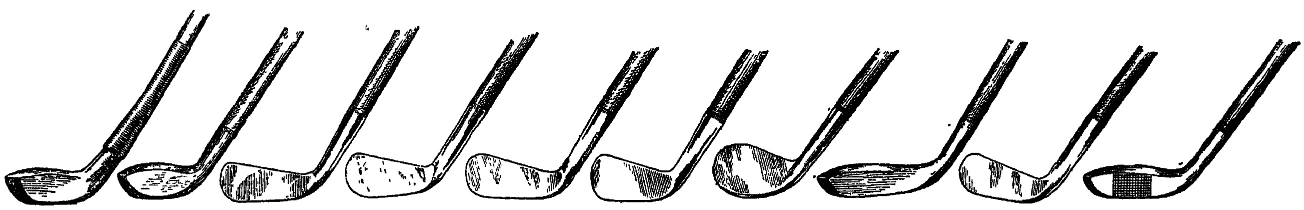
Moreover, ladies have learned to play golf. This is not stating the fact too widely nor too forcibly, for though it is true that before 1885 many played on the short links of St Andrews, North Berwick, Westward Ho, and elsewhere, still it was virtually unknown that they should play on the longer courses, which till then had been in the undisputed possession of the men. At many places women now have their separate links, at others they play on the same course as the men. But even where links are set apart for women, they are far different from the little courses that used to be assigned to them. They are links only a little less formidable in their bunkers, a little less varied in their features than those of men. The ladies have their annual Championship, which they play on the long links of the men, sometimes on one, sometimes on another, but always on courses of the first quality, demanding the finest display of golfing skill.

The claim that England has made to a golfing fellowship with Scotland has been conceded very strikingly by the admission of two English greens, those of Hoylake and of Sandwich, into the exclusive list of the links on which the Open Championship of the game is decided. Before England had so fully assimilated Scotland's game this great annual contest was waged at St Andrews, Musselburgh, and Prestwick in successive years. Now the ancient green of Musselburgh, somewhat worn out with length of hard and gallant service, and moreover, as a nine-holes course inadequately accommodating the numbers who compete in the Championships to-day, has been superseded by the course at Muirfield as a championship arena, and the greens of Sandwich and Hoylake, as just now stated, have been included in the list, which thus contains at present five greens in place of the old

three. The Amateur Championship also has been played on these two greens of England, as well as on the three that are honoured in Scotland as championship courses; but since this championship of the amateurs is of more modern institution than the Open Championship, and indeed owed its institution chiefly to the initiative of the English club at Hoylake, there is not in this circumstance the same marked proof that Scotland concedes to England share in the general golfing councils.

While golf had been making itself a force in the Southern kingdom, the professional element—men who had learned the game from childhood, had become past-masters, were capable of giving instruction, and also of making clubs and balls and looking after the greens on which golf was played—had at first been taken from the northern side of the Border. But when golf had been started long enough in England for the little boys who were at first employed as "caddies"—in carrying the players' clubs—to grow to sufficient strength to drive the ball as far as their masters, it was inevitable that out of the number who thus began to play in their boyhood some few should develop an exceptional talent for the game. This, in fact, actually happened, and English golfers, both of the amateur and the professional classes, have proved themselves so adept at Scotland's game, that the championships in either the Open or the Amateur competitions have been won more often by English than by Scottish players of late years. Probably in the United Kingdom to-day there are as many English as Scottish professional golf players, and their relative number is increasing.

Golf has also "caught on," to use the American expression, in the United States. To the American of 1890 golf was largely an unknown thing. Since then, however, golf has become a very much greater factor in the life of the upper and upper-middle classes in the United States than it ever has been in England or Scotland. Golf to the English and the Scots meant only one among several of the sports and pastimes that take the man and the woman of the upper and upper-middle classes into the country and the fresh air. To the American of like status golf came as the one thing to take him out of his towns and give him a reason for exercise in the country. Before golf came to amuse them there were only a very few of the rather Anglicized Americans who in the Eastern States found any active amusements at all out of doors. To-day golf has become an absorbing interest in the Eastern States of America, and indeed all over the Northern Continent, but it is in the Eastern States that it has made most difference in the life of the classes with whom it has become fashionable. The others, the Westerners and Southerners, found more excuses before the coming of golf for being in the open country air. It is in the Eastern States more especially that it has had so much influence in making the people live and exercise out of doors. In a truly democratic spirit the American woman golfer plays on a perfect equality with the American man. She does not compete in the men's championships; she has championships of her own; but she plays, without question, on the same links. There is no suggestion of relegating her, as a certain cynical writer in the Badminton volume on golf described it, to a waste corner, a kind of "Jews' Quarter," of the links. And the Americans have taken up golf in the spirit of a sumptuous and opulent people, spending money on magnificent club-houses beyond the finest dreams of the Englishman or the Scot.



Types of Golf Clubs.
1, Driver; 2, Brassy; 3, Cleek; 4, Driving Mashie; 5, Iron; 6, Mashie; 7, Niblick; 8, Wooden Putter; 9, Putter; 10, Baffing Spoon.

So much enthusiasm and so much golf in America have not failed to make their influence felt in the United Kingdom. Naturally and inevitably they have created a strong demand for professional instruction, both by example and by precept, and for professional advice and assistance in the laying-out and upkeep of the many new links that have been created in all parts of the States, sometimes out of the least promising material. By the offer of great prizes for exhibition matches, and of wages that are to the British rate on the scale of the dollar to the shilling, they have attracted many of the best Scottish and English professionals to pay them longer or shorter visits as the case may be, and thus a new opening has been created for the energies of the professional golfing class.

Changes in rules and play.

There have been some slight changes of detail and arrangement in the rules of the game. A new class of golfer has arisen, requiring a code of rules framed rather more exactly than the older code. The Scottish golfer, who was "teethed" on a golf club, as Mr Andrew Lang has described it, imbibed all the traditions of the game with his natural sustenance. Very few rules sufficed for him. But when the Englishman, and still more the American (less in touch with the traditions), began to play golf as a new game, then they began to ask for a code of rules that should be lucid and illuminating on every point—an ideal perhaps impossible to realize. It was found, at least, that the code put forward by the Royal and Ancient Club of St Andrews did not realize it adequately. Nevertheless the new golfers were very loyal indeed to the club that had ever of old held, by tacit consent, the position of fount of golfing legislation. The Royal and Ancient Club was appealed to by English golfers to step into the place, analogous to that of the Marylebone Cricket Club in cricket, that they were both willing and anxious to give it. It was a place that the club at St Andrews did not in the least wish to occupy, but the honour was thrust so insistently upon it, that there was no declining. The latest effort to meet the demands for some more satisfactory legislation on the thousand and one points that continually must arise for decision in course of playing a game of such variety as golf, consists of the appointment of a standing committee, called the "Rules of Golf Committee." Its members all belong to the Royal and Ancient Club; but since this club draws its membership from all parts of the United Kingdom, this restriction is quite consistent with a very general representation of the views of north, south, east, and west—

from Westward Ho and Sandwich to Dornoch, and all the many first-rate links of Ireland—on the committee. Ireland has, indeed, some of the best links in the kingdom, and yields to neither Scotland nor England in enthusiasm for the game. This committee, after a general revision of the rules into the form in which they now stand, considers every month, either by meeting or by correspondence, the questions that are sent up to it by clubs or by individuals; and the committee's answers to these questions have the force of law until they have come before the next general meeting of the Royal and Ancient Club at St Andrews, which may confirm or may reject them at will. The ladies of Great Britain manage otherwise. They have a Golfing Union which settles questions for them; but since this union itself accepts as binding the answers given by the Rules of Golf Committee, they really arrive at the same conclusions by a slightly different path. Nor does the American Union, governing the play of men and women alike in the States, really act differently. The Americans, naturally, reserve to themselves freedom to make their own rules, but in practice they conform to the legislation of Scotland, with the exception of a more drastic definition of the status of the amateur player, which seems to be required by the circumstances of the game in the States.

A slight modification has been effected in the implements of the game. The tendency of the modern wooden clubs is to be short in the head as compared with the clubs of, say, 1880 or 1885. The advantage claimed (probably with justice) for this shape is that it masses the weight behind the point on which the ball is struck (see Fig.). Better material, both in the wood of the clubs and in the gutta-percha of which the balls are made, is a consequence of the increased demand for these articles and the increased competition among their makers. Whereas, under the old conditions, a few workers at the few greens then in existence were enough to supply the golfing wants, now there is a very large industry in golf club and ball making, which not only employs workers in the local club-makers' shops all the kingdom over, but is an important branch of the commerce of the stores and of the big athletic outfitters.

With all this growth of interest in golf, it is only natural that more and more attention should have been directed to efforts at discovering its origin, but so far all in vain. One of the most ancient and most interesting of the pictures in which the game is portrayed is the tail-piece to an illuminated *Book of Hours*, made at Bruges at the beginning of the 16th century. The original is in the British Museum. The players, three in number, have but one club apiece. The heads of the clubs are steel or steel covered. They play with a ball each. That which gives this picture a peculiar interest over the many pictures of Dutch schools that portray the game in progress is that most of them show it on the ice, the putting being at a stake. In this *Book of Hours* they are putting at a hole in the turf, as in our modern golf. It is scarcely to be doubted that the game is of Dutch origin, and that it has been in favour since very early days. Farther than that our knowledge does not go. The early Dutchmen played golf, they painted golf, but they did not write it.

Literature of the game.

With our own devotees of golf the case has been very different, and the literature of the game has grown to some considerable bulk. For many years it was practically comprised in the fine work by Mr Clark, *Golf: A Royal and Ancient Game*, together with two handbooks on the game by Mr Chambers and by Mr Forgan respectively, and the *Golfiana Miscellanea* of Mr Stewart. A small book by the present writer, named *Hints on Golf*, was very shortly followed by a much more important work by the late Sir Walter Simpson, Bart., called *The Art of Golf*, a title which sufficiently explains itself. The Badminton Library book on *Golf* attempted to collect into one volume the most interesting historical facts known about the game, with *obiter dicta* and advice to learners, and, on similar didactic lines, books have been written by Mr H. C. S. Everard, Mr Garden Smith, and W. Park, the professional player. Mr H. J. Whigham, sometime amateur champion golfer of the United States, has given us a book about the game in that country. *The Book of Golf and Golfers*, compiled, with assistance, by the present writer, is in the first place a picture-gallery of famous golfers in their respective attitudes of play. Much interesting lore is contained in the *Golfing Annual*, which has now been published yearly for several years, and in the pages of *Golf*, which has now become *Golf Illustrated*, a weekly paper devoted to the game. Among works that have primarily a local interest, but yet contain much of historical value about the game, may be cited the *Golf Book of East Lothian*, by the Rev. John Kerr, and the *Chronicle of Blackheath Golfers*, by Mr W. E. Hughes.

Method of play.

By way of amplifying the rather dry definitions given in the rules, it may be said, for the benefit of the unlearned, that the game of golf consists in hitting the ball over a great extent of country, preferably of that sand-hill nature which is found by the sea-side, and finally hitting or "putting" it into a little hole of some four inches diameter cut in the turf. The place of the hole is commonly marked by a flag. Eighteen is the recognized number of these holes on a full course, and they are at varying distances apart, from one hundred yards up to anything between a quarter and half a mile. For the various strokes required to achieve the hitting of the ball over the great hills, and finally putting it into the small hole, a number of different "clubs" has been devised to suit the different positions in which the ball may be found and the different directions in which it is wished to propel it (see Fig.). At the start for each hole the ball may be placed on a favourable position (*e.g.*, "teed" on a small mound of sand) for striking it, but after that it may not be touched, except with the club, until it is hit into the next hole. A "full drive," as the farthest distance that the ball can be hit is called, is about two hundred yards in length, of which some three-quarters will be traversed in the air, and the rest by bounding or running over the ground. It is easily to be understood that when the ball is lying on the turf behind a tall sand-hill, or in a bunker, a differently-shaped club is required for raising it over such an obstacle from that which is needed when it is placed on the tee to start with; and again, that another club is needed to strike the ball out of a cup or out of heavy grass. It is this variety that gives the game its charm. Each player plays with his own ball, with no interference from his opponent, and the object of each is to hit the ball from the starting-point into each successive hole in the fewest strokes. The player who at the end of the round (*i.e.*, of the course of eighteen holes) has won the majority of the holes is the winner of the round; or the decision may be reached before the end of the round by one side gaining more holes than there remain to play. For instance, if one player be four holes to the good, and only three holes remain to be played, it is evident that the former must be the winner, for even if the latter win every remaining hole, he still must be one to the bad at the finish.

Championship.

The Amateur Championship is decided by a tournament in matches thus played, each defeated player retiring, and his opponent passing on into the next round. In the case of the Open Championship, and in most medal competitions, the scores are differently reckoned—each man's total score (irrespective of his relative merit at each hole) being reckoned at the finish against the total score of the other players in the competition. There is also a species of competition called "bogey" play, in which each man plays against a "bogey" score—a score fixed for each hole in the round before starting—and his position in the competition relatively to the other players is determined by the number of holes that he is to the good or to the bad of the "bogey" score at the end of the round. The player who is most holes to the good, or fewest holes to the bad, wins the competition. It may be mentioned incidentally that golf occupies the almost unique position of being the only sport in which even a single player can enjoy his game, his opponent in this event being "Colonel Bogey"—more often than not a redoubtable adversary.

The links which have been thought worthy, by reason of their geographical positions and their merits, of being the scenes on which the golf championships are fought out, are, as we have already said, three in Scotland—St Andrews, Prestwick, and Muirfield—and two in England—Hoylake and Sandwich. This brief list is very far from being complete as regards links of first-class quality in Great Britain. Besides the five named, there are in Scotland—Carnoustie, North Berwick, Cruden Bay, Nairn, Aberdeen, Dornoch, Troon, Machrihanish, South Uist, Islay, Gullane, Luffness, and many more. In England there are—Westward Ho, Bembridge, Littlestone, Deal, Great Yarmouth, Brancaster, Seaton

Carew, Formby, Lytham, Harlech, Burnham, among the seaside ones; while of the inland, some of them of very fine quality, we cannot even attempt a selection, so large is their number and so variously estimated their comparative merits. Ireland has Portrush, Newcastle, Portsalon, Dollymount, and many more of the first class; and there are excellent courses in the Isle of Man. In America many fine courses have been constructed. There is not a British colony of any standing that is without its golf course—Australia, India, South Africa, all have their golf championships, which are keenly contested. Canada has had courses at Quebec and Montreal for many years, and the Calcutta Golf Club, curiously enough, is the oldest established (next to the Blackheath Club), the next oldest being the club at Pau in the Basses-Pyrénées.

The Open Championship of golf was started in 1860 by the Prestwick Club giving a belt to be played for annually under the condition that it should become the property of any who could win it thrice in succession.

The following is the list of the champions:—

1860.	W. Park, Musselburgh	174—at Prestwick.
1861.	Tom Morris, sen., Prestwick	163—at Prestwick.
1862.	Tom Morris, sen., Prestwick	163—at Prestwick.
1863.	W. Park, Musselburgh	168—at Prestwick.
1864.	Tom Morris, sen., Prestwick	160—at Prestwick.
1865.	A. Strath, St Andrews	162—at Prestwick.
1866.	W. Park, Musselburgh	169—at Prestwick.
1867.	Tom Morris, sen., St Andrews	170—at Prestwick.
1868.	Tom Morris, jun., St Andrews	154—at Prestwick.
1869.	Tom Morris, jun., St Andrews	157—at Prestwick.
1870.	Tom Morris, jun., St Andrews	149—at Prestwick.

Tom Morris, junior, thus won the belt finally, according to the conditions. In 1871 there was no competition; but by 1872 the three clubs of St Andrews, Prestwick, and Musselburgh had subscribed for a cup which should be played for over the course of each subscribing club successively, but should never become the property of the winner. In later years the course at Muirfield was substituted for that at Musselburgh, and Hoylake and Sandwich were admitted into the list of championship courses. Up to 1891, inclusive, the play of two rounds, or thirty-six holes, determined the championship, but from 1892 onwards the result has been determined by the play of seventy-two holes.

After the interregnum of 1871, the following were the champions:—

1872.	Tom Morris, jun., St Andrews	166—at Prestwick.
1873.	Tom Kidd, St Andrews	179—at St Andrews.
1874.	Mungo Park, Musselburgh	159—at Musselburgh.
1875.	Willie Park, Musselburgh	166—at Prestwick.
1876.	Bob Martin, St Andrews	176—at St Andrews.
1877.	Jamie Anderson, St Andrews	160—at Musselburgh.
1878.	Jamie Anderson, St Andrews	157—at Prestwick.
1879.	Jamie Anderson, St Andrews	170—at St Andrews.
1880.	Bob Fergusson, Musselburgh	162—at Musselburgh.
1881.	Bob Fergusson, Musselburgh	170—at Prestwick.
1882.	Bob Fergusson, Musselburgh	171—at St Andrews.
1883.	W. Fernie, Dumfries	159—at Musselburgh.
1884.	Jack Simpson, Carnoustie	160—at Prestwick.
1885.	Bob Martin, St Andrews	171—at St Andrews.
1886.	D. Brown, Musselburgh	157—at Musselburgh.
1887.	Willie Park, jun., Musselburgh	161—at Prestwick.
1888.	Jack Burns, Warwick	171—at St Andrews.
1889.	Willie Park, jun., Musselburgh	155—at Musselburgh.
1890.	Mr John Ball, jun., Hoylake	164—at Prestwick.
1891.	Hugh Kirkaldy, St Andrews	166—at St Andrews.
1892.	Mr H. H. Hilton, Hoylake	305—at Muirfield.
1893.	W. Auchterlonie, St Andrews	322—at Prestwick.
1894.	J. H. Taylor, Winchester	326—at Sandwich.
1895.	J. H. Taylor, Winchester	322—at St Andrews.
1896.	H. Vardon, Scarborough	316—at Muirfield.
1897.	Mr H. H. Hilton, Hoylake	314—at Hoylake.
1898.	H. Vardon, Scarborough	307—at Prestwick.
1899.	H. Vardon, Scarborough	310—at Sandwich.
1900.	J. H. Taylor, Richmond	309—at St Andrews.
1901.	J. Braid, Romford	309—at Muirfield.

The Amateur Championship is of far more recent institution. Its winners have been:—

1886.	Mr Horace Hutchinson	at St Andrews.
1887.	Mr Horace Hutchinson	at Hoylake.
1888.	Mr John Ball	at Prestwick.
1889.	Mr J. E. Laidlay	at St Andrews.
1890.	Mr John Ball	at Hoylake.
1891.	Mr J. E. Laidlay	at St Andrews.
1892.	Mr John Ball	at Sandwich.
1893.	Mr P. Anderson	at Prestwick.
1894.	Mr John Ball	at Hoylake.
1895.	Mr L. Balfour-Melville	at St Andrews.
1896.	Mr F. G. Tait	at Sandwich.
1897.	Mr J. T. Allan	at Muirfield.
1898.	Mr John Ball	at Prestwick.
1899.	Mr F. G. Tait	at Hoylake.
1900.	Mr H. H. Hilton	at Sandwich.
1901.	Mr H. H. Hilton	at St Andrews.

Glossary of Technical Terms used in the Game.

Addressing the Ball.—Putting oneself in position to strike the ball.

All Square.—Term used to express that the score stands level, neither side being a hole up.

Baff.—To strike the ground with the club when playing, and so loft the ball unduly.

Baffy.—A short wooden club, with laid-back face, for lofting shots.

Bogey.—The number of strokes which a good average player should take to each hole. This imaginary player is usually known as "Colonel Bogey," and plays a fine game.

Brassy.—A wooden club with a brass sole (see Fig.).

Bulger.—A driver in which the face "bulges" into a convex shape. The head is shorter than in the older-fashioned driver.

Bunker.—A sand-pit.

Caddie.—The person who carries the club (from French *cadet*).

Cleek.—The iron-headed club that is capable of the farthest drive of any of the clubs with iron heads (see Fig.).

Dead.—A ball is said to be "dead" when so near the hole that the putting it in in the next stroke is a "dead" certainty. A ball is said to "fall dead" when it pitches with hardly any run.

Divot.—A piece of turf cut out in the act of playing, which, be it noted, should always be replaced before the player moves on.

Dormy.—One side is said to be "dormy" when it is as many holes to the good as remain to be played—so that it cannot be beaten.

Driver.—The longest driving club, used when the ball lies very well and a long shot is needed (see Fig.).

Foozle.—Any very badly missed or bungled stroke.

"Fore!"—A cry of warning to people in front.

Foursome.—A match in which four persons engage, two on each side playing alternately with the same ball.

Green.—(*a*) The links as a whole; (*b*) the "putting-greens" around the holes.

Grip.—(*a*) The part of the club-shaft which is held in the hands while playing; (*b*) the grasp itself—*e.g.*, "a firm grip," "a loose grip," are common expressions.

Half-Shot.—A shot played with something less than a full swing.

Halved.—A hole is "halved" when both sides have played it in the same number of strokes. A round is "halved" when each side has won and lost the same number of holes.

Hanging.—Said of a ball that lies on a slope inclining downwards in regard to the direction in which it is wished to drive.

Hazard.—A general term for bunker, whin, long grass, roads, and all kinds of bad ground.

Heel.—To hit the ball with a pulling movement, so as to send it too much to the left: in a sense, the opposite of *slice.*

Honour.—The privilege (which its holder is not at liberty to decline) of striking off first from the tee.

Iron.—An iron-headed club intermediate between the cleek and lofting mashie. There are driving irons and lofting irons according to the purposes for which they are intended (see Fig.).

Lie.—(*a*) The angle of the club-head with the shaft (*e.g.*, a "flat lie," "an upright lie"); (*b*) the position of the ball on the ground (*e.g.*, "a good lie," "a bad lie").

Like-as-we-Lie.—Said when both sides have played the same number of strokes.

Line.—The direction in which the hole towards which the player is progressing lies with reference to the present position of his ball.

Mashie.—An iron club with a short head (see Fig.). The *lofting mashie* has the blade much laid back, for playing a short lofting shot. The *driving mashie* (see Fig.) has the blade less laid back, and is used for longer, less lofted shots.

Match-Play.—Play in which the score is reckoned by holes won and lost.

Medal-Play.—Play in which the score is reckoned by the total of strokes taken on the round.

Niblick.—A short stiff club with a short, laid back, iron head, used for getting the ball out of a very bad lie (see Fig.).

Press.—To strive to hit harder than you can hit with accuracy.

Putt.—To play the short strokes near the hole.

Putter.—The club used for playing the short strokes near the hole. Some have a wooden head, some an iron head (see Fig.).

Rub-of-the-Green.—Any chance deflection that the ball receives as it goes along.

Run Up.—To send the ball low and close to the ground in approaching the hole—opposite to lofting it up.

Scratch Player.—Player who receives no odds in handicap competitions.

Slice.—To hit the ball with a cut across it, so that it flies curving to the right.

Stance.—(*a*) The place on which the player has to stand when playing—*e.g.*, "a bad stance," "a good stance," are common expressions; (*b*) the position relative to each other of the player's feet.

Stymie.—When one ball lies in a straight line between another and the hole the first is said to "stymie," or "to be a stymie to" the other—from an old Scottish word given by Jamieson to mean "the faintest form of anything." The idea probably was, the "stymie" only left you the "faintest form" of the hole to aim at.

Tee.—The little mound of sand on which the ball is generally placed for the first drive to each hole.

Teeing-Ground.—The place marked as the limit, outside of which it is not permitted to drive the ball off. This marked-out ground is also sometimes called "the tee."

Top.—To hit the ball above the centre, so that it does not rise much from the ground.

Wrist-Shot.—A shot less in length than a half-shot, but longer than a putt.

Rules of Golf.

1. *Definitions.*—(*a*) The game of golf is played by sides, each playing its own ball. A side consists either of one or of two players. If one player play against another, the match is called "a single." If two play against two, it is called "a foursome." A single player may play against two, when the match is called "a threesome," or three players may play against each other, each playing his own ball, when the match is called "a three-ball match."

(*b*) The game consists in each side playing a ball from a teeing-ground into a hole by successive strokes, and the hole is won by the side which holes its ball in fewer strokes than the opposite side, except as otherwise provided for in the rules. If the sides hole out in the same number of strokes, the hole is halved.

(*c*) The teeing-ground shall be indicated by two marks placed in a line, as nearly as possible at right angles to the course.

(*d*) The term "putting-green" shall mean all ground within 20 yards of the hole, except hazards. The hole shall be 4¼ inches in diameter, and at least 4 inches deep.

(*e*) A "hazard" shall be any bunker, water (except casual water), sand, path, road, railway, whin, bush, rushes, rabbit scrape, fence, or ditch. Sand blown on to the grass, or sprinkled on the course for its preservation, bare patches, snow, and ice are not hazards. Permanent grass within a hazard shall not be considered part of the hazard.

(*f*) The term "through the green" shall mean all parts of the course except "hazards" and the putting-green which is being played to.

(*g*) The term "out of bounds" shall mean any place outside the defined or recognized boundaries of the course.

(*h*) "Casual water" shall mean any temporary accumulation of water (whether caused by rainfall or otherwise) which is not one of the ordinary and recognized hazards of the course.

(*i*) A ball shall be "in play" as soon as the player has made a stroke at the teeing-ground in each hole, and shall remain in play until holed out, except when lifted in accordance with the rules.

(*j*) A ball shall be considered to have "moved" only if it leave its original position in the least degree, and stop in another; but if it merely oscillate, without finally leaving its original position, it shall not be considered to have "moved."

(*k*) A ball shall be considered "lost" if it be not found within five minutes after the search for it is begun.

(*l*) A "match" shall consist of one round of the links, unless it be otherwise agreed.

A match is won by the side which is leading by a number of holes greater than the number of holes remaining to be played. If each side win the same number of holes, the match is halved.

(*m*) A "stroke" shall be any movement of the ball caused by the player, except as provided for in Rule 4, or any downward movement of the club made with the intention of striking the ball.

(*n*) A "penalty stroke" is a stroke added to the score of a side under certain rules, and shall not affect the rotation of play.

(*o*) The privilege of playing first from a teeing-ground is called "the honour."

(*p*) "Addressing the ball" shall mean that a player has taken up his position and grounded his club, or if in a hazard, that he has taken up his position preparatory to striking the ball.

(*q*) The reckoning of strokes is kept by the terms—"the odd," "two more," "three more," &c., and "one off three," "one off two," "the like." The reckoning of holes is kept by the terms—so many "holes up," or "all even," and so many "to play."

2. A match begins by each side playing a ball from the first teeing-ground.

The player who shall play first on each side shall be named by his own side.

The option of taking the honour at the first teeing-ground shall be decided, if necessary, by lot.

A ball played from in front of, or outside of, or more than two club lengths behind the two marks indicating the teeing-ground, or played by a player when his opponent should have had the honour, may be at once recalled by the opposite side, and may be re-teed.

The side which wins a hole shall have the honour at the next teeing-ground. If a hole has been halved the side which had the honour at the last teeing-ground shall again have the honour.

On beginning a new match the winner of the long match in the previous round shall have the honour, or if the previous match was halved the side which last won a hole shall have the honour.

3. A player shall not play while his ball is moving, under the penalty of the loss of the hole. But if the ball begin to move while the player is making his upward or downward swing, he shall incur no penalty, except as provided for in Rules 10, 18, and 27, and a stroke lost under Rule 27 shall not in these circumstances be counted as a stroke of the player.

4. If the ball fall or be knocked off the tee in addressing it, no penalty shall be incurred, and it may be replaced, and if struck when moving no penalty shall be incurred.

5. In a threesome or foursome the partners shall strike off alternately from the teeing-grounds, and shall strike alternately during the play of the hole.

If a player play when his partner should have done so, his side shall lose the hole.

6. When the balls are in play, the ball farthest from the hole which the players are approaching shall be played first, except as otherwise provided for in the rules. If a player play when his opponent should have done so, the opponent may at once recall the stroke. A ball so recalled shall be dropped as near as possible to the place where it lay, without penalty.

7. The ball must be fairly struck at, not pushed, scraped, nor spooned, under penalty of the loss of the hole.

8. A ball must be played wherever it lies or the hole be given up, except as otherwise provided for in the rules.

9. Unless with the opponent's consent, a ball in play shall not be moved, nor touched before the hole is played out, under penalty of one stroke, except as otherwise provided for in the rules. But the player may touch his ball with his club in the act of addressing it, without penalty.

If the player's ball move the opponent's ball through the green, the opponent, if he choose, may drop a ball (without penalty) as near as possible to the place where it lay, but this must be done before another stroke is played.

10. Any loose impediment (not being in or touching a hazard) which is within a club length of the ball may be removed. If the player's ball move after any such loose impediment has been touched by the player, his partner, or either of their caddies, the penalty shall be one stroke. If any loose impediment (not being on the putting-green) which is more than a club length from the ball be removed, the penalty shall be the loss of the hole.

11. Any vessel, wheel-barrow, tool, roller, grass-cutter, box, or similar obstruction may be removed. If a ball be moved in so doing, it may be replaced without penalty. A ball lying on or touching such obstruction, or on clothes, nets, or ground under repair or covered up or opened for the purpose of the upkeep of the links, may be lifted and dropped without penalty, as near as possible to the place where it lay, but not nearer the hole. A ball lifted in a hazard, under such circumstances, shall be dropped in the hazard.

A ball lying in a golf hole or flag hole, or in a hole made by the green-keeper, may be lifted and dropped without penalty as near as possible to the place where it lay, but not nearer the hole.

12. Before striking at a ball in play, the player shall not move, bend, nor break anything fixed or growing near the ball, except in the act of placing his feet on the ground for the purpose of addressing the ball, in soling his club to address the ball, and in his upward or downward swing, under penalty of the loss of the hole, except as otherwise provided for in the rules.

13. When a ball lies in or touches a hazard, nothing shall be done to improve its lie; the club shall not touch the ground, nor shall anything be touched or moved before the player strikes at the ball, subject to the following exceptions:—(1) The player may place his feet firmly on the ground for the purpose of addressing the ball; (2) in addressing the ball, or in the upward or downward swing, any grass, bent, whin, or other growing substance, or the side of a bunker, wall, paling, or other immovable obstacle may be touched; (3) steps or planks placed in a hazard by the Green Committee for access to or egress from such hazard may be removed, and if a ball be moved in so doing, it may be replaced without penalty; (4) any loose impediments may be removed from the putting-green; (5) the player shall be entitled to find his ball as provided for by Rule

30. The penalty for a breach of this rule shall be the loss of the hole.

14. A player or caddie shall not press down nor remove any irregularities of surface near a ball in play. Dung, worm-casts, or mole-hills may be removed (but not pressed down) without penalty. The penalty for a breach of this rule shall be the loss of the hole.

15. If a ball lie or be lost in water, the player may drop a ball, under penalty of one stroke. But if a ball lie or be lost (1) in casual water through the green, a ball may be dropped without penalty; (2) in water in a hazard, or in casual water in a hazard, a ball may be dropped behind the hazard, under penalty of one stroke; (3) in casual water on a putting-green, a ball may be placed by hand behind the water, without penalty.

16. When a ball has to be dropped, the player himself shall drop it. He shall face the hole, stand erect behind the hazard or casual water, keep the spot from which the ball was lifted (or in the case of water or casual water, the spot at which it entered) in a line between himself and the hole, and drop the ball behind him from his head, standing as far behind the hazard or casual water as he may please. If it be impossible to drop the ball behind the hazard or casual water, it shall be dropped as near as possible to the place where it lay, but not nearer the hole. If the ball so dropped touch the player dropping it, there shall be no further penalty, and if the ball roll into a hazard, it may be re-dropped without further penalty.

17. When the balls lie within six inches of each other on a putting-green, or within a club length of each other through the green or in a hazard (the distance to be measured from their nearest points), the ball nearer the hole may, at the option of either the player or the opponent, be lifted until the other is played, and shall then be replaced as near as possible to the place where it lay. If the ball farther from the hole be moved in so doing, or in measuring the distance, it shall be replaced without penalty. If the lie of the lifted ball be altered by the player in playing, the ball may be placed in a lie as nearly as possible similar to that from which it was lifted, but not nearer the hole.

18. Any loose impediments may be removed from the putting-green, irrespective of the position of the player's ball. The opponent's ball may not be moved except as provided for by the immediately preceding rule. If the player's ball move after any loose impediment lying within six inches of it has been touched by the player, his partner, or either of their caddies, the penalty shall be one stroke.

19. When the ball is on the putting-green the player or his caddie may remove (but not press down) sand, earth, dung, worm-casts, mole-hills, snow, or ice lying round the hole or in the line of his putt. This shall be done by brushing lightly with the hand only across the putt and not along it. Dung may be removed by a club, but the club must not be laid with more than its own weight upon the ground. The line of the putt must not be touched, except with the club immediately in front of the ball, in the act of addressing it, or as above authorized. The penalty for a breach of this rule is the loss of the hole.

20. When the ball is on the putting-green, no mark shall be placed, nor line drawn as a guide. The line of the putt may be pointed out by the player's caddie, his partner, or his partner's caddie, but the person doing so must not touch the ground.

The player's caddie, his partner, or his partner's caddie may stand at the hole, but no player nor caddie shall endeavour, by moving or otherwise, to influence the action of the wind upon the ball.

The penalty for a breach of this rule is the loss of the hole.

21. When on the putting-green, a player shall not play until the opponent's ball is at rest, under penalty of one stroke.

22. Either side is entitled to have the flag-stick removed when approaching the hole. If the ball rest against the flag-stick when in the hole, the player shall be entitled to remove the stick, and, if the ball fall in, it shall be deemed as having been holed out at the last stroke. If the player's ball knock in the opponent's ball, the latter shall be deemed as having been holed out at the last stroke. If the player's ball move the opponent's ball, the opponent, if he choose, may replace it, but this must be done before another stroke is played. If the player's ball stop on the spot formerly occupied by the opponent's ball, and the opponent declare his intention to replace, the player shall first play another stroke, after which the opponent shall replace and play his ball. If the opponent's ball lie on the edge of the hole, the player, after holing out, may knock it away, claiming the hole if holing at the like, and the half if holing at the odd, provided that the player's ball does not strike the opponent's ball and set it in motion. If after the player's ball is in the hole the player neglect to knock away the opponent's ball, and it fall in also, the opponent shall be deemed to have holed out at his last stroke.

23. If a ball *in motion* be stopped or deflected by any agency outside the match, or by the forecaddie, the ball must be played from where it lies, and the occurrence submitted to as a "rub of the green." If a ball lodge in anything moving, a ball shall be dropped as near as possible to the place where the object was when the ball lodged in it, without penalty. If a ball *at rest* be displaced by any agency outside the match, excepting wind, the player shall drop a ball as near as possible to the place where it lay, without penalty. On the putting-green the ball shall be replaced by hand, without penalty.

24. If the player's ball strike, or be moved by an opponent or an opponent's caddie or clubs, the opponent shall lose the hole.

25. If the player's ball strike, or be stopped by, himself or his partner, or either of their caddies or clubs, his side shall lose the hole.

26. If the player, when making a stroke, strike the ball twice, the penalty shall be one stroke.

27. If the player, when not intending to make a stroke, or his partner or either of their caddies, move his or their ball, or by touching anything cause it to move, when it is in play, the penalty shall be one stroke. If a ball in play move, after the player has grounded his club in the act of addressing it, or, when in a hazard, if he has taken up his stand to play it, he shall be deemed to have caused it to be moved, and shall lose a stroke, which shall be counted as a stroke of the player, except as provided in Rule 3.

28. If a player play the opponent's ball, his side shall lose the hole, unless (1) the opponent then play the player's ball, whereby the penalty is cancelled, and the hole must be played out with the balls thus exchanged, or (2) the mistake occur through wrong information given by the opponent or his caddie, in which case there shall be no penalty, but the mistake, if discovered before the opponent has played, must be rectified by placing a ball as near as possible to the place where the opponent's ball lay.

If it be discovered before either side has struck off from the next teeing-ground (or, after playing the last hole in the match, before any of the players have left the green) that one side has played out the hole with the ball of a party not engaged in the match, that side shall lose that hole.

29. If a ball be lost, except as otherwise provided for in the rules, the player's side shall lose the hole; but if both balls be lost, the hole shall be considered halved.

30. If a ball be lost in fog, bent, whins, long grass, or the like, only so much thereof shall be touched as will enable the player to find his ball. The penalty for a breach of this rule shall be the loss of the hole.

31. If a ball be driven out of bounds, a ball shall be dropped at the spot from which the stroke was played, under penalty of loss of the distance.

32. In a three-ball match, if a player consider that an opponent's ball on the putting-green might interfere with his stroke, he may require the opponent either to lift or hole out his ball at the opponent's discretion.

If an opponent consider (1) that his own ball, if left, might be of assistance to the player, he is entitled to lift it, or hole out at his discretion; or (2) that the ball of the other opponent might be of such assistance, he may require that it be either lifted or holed out at the other opponent's discretion.

33. A player shall not ask for advice from any one except his own caddie, his partner, or his partner's caddie, nor shall he willingly be otherwise advised in any way whatever, under penalty of the loss of the hole.

34. If a ball split into separate pieces, another ball may be put down where the largest portion lies, or if two pieces are apparently of equal size, it may be put where either piece lies, at the option of the player. If a ball crack or become unfit for play, the player may change it, on intimating to his opponent his intention to do so. Mud adhering to a ball shall not be considered as making it unfit for play.

35. If a dispute arise on any point, the players have the right of determining the party or parties to whom it shall be referred, but should they not agree, either side may refer it to the Rules of Golf Committee, whose decision shall be final. If the point in dispute be not covered by the Rules of Golf, the arbiters must decide it by equity.

Special Rules for Stroke Competitions.

1. In stroke competitions, the competitor who holes the stipulated course in fewest strokes shall be the winner.

2. If the lowest scores be made by two or more competitors, the tie or ties shall be decided by another round to be played on the same day. But if the Green Committee determine that to be inexpedient or impossible, they shall then appoint the following or some subsequent day whereon the tie or ties shall be decided.

3. New holes shall be made for stroke competitions, and thereafter no competitor, before starting, shall play any stroke on a putting-green, under penalty of disqualification.

4. The scores shall be kept by a special marker, or by the competitors noting each other's scores. The scores marked shall be

checked after each hole. On completion of the round, the score of the competitor shall be signed by the marker, countersigned by the competitor, and handed to the secretary or his deputy, after which, unless it be found that a card returned shows a score below that actually played (in which case the competitor shall be disqualified), no correction or alteration can be made.

5. If a competitor play from outside the limits of the teeing-ground, the penalty shall be disqualification.

6. If a ball be lost (except as otherwise provided for in the Rules of Golf), the competitor shall return as near as possible to the spot from which the lost ball was struck, tee a ball, and lose a stroke. The lost ball shall continue in play, if it be found before the player has struck another ball.

7. If a competitor's ball strike himself, his clubs or caddie, the penalty shall be one stroke.

8. If a competitor's ball strike another competitor, or his clubs or caddie, it is a "rub of the green," and the ball shall be played from where it lies. If a competitor's ball which is at rest be moved by another competitor or his caddie, or his club, or his ball, or by any outside agency excepting wind, it shall be replaced as near as possible to the place where it lay, without penalty.

9. A competitor shall hole out with his own ball at every hole, under penalty of disqualification. But if it be discovered before he has struck off from the next teeing-ground, or, if the mistake occur at the last hole, before he has handed his card to the secretary or his deputy, that he has not holed out with his own ball, he shall be at liberty to return and hole out with his own ball, without penalty.

10. A ball may be lifted out of a difficulty of any description, and teed, if possible, behind it, under penalty of two strokes. If it be impossible to tee the ball behind the difficulty, it shall be teed as near as possible to the place where it lay, but not nearer the hole.

11. All balls shall be holed out, under penalty of disqualification. When a competitor's ball is within 20 yards of the hole, the competitor shall not play until the flag has been removed, under penalty of one stroke. If the ball nearer the hole might either interfere with the competitor's stroke, or in any way assist the competitor, such ball must be holed out or lifted, at the owner's option. Through the green a competitor may have any other competitor's ball lifted, if he find that it interferes with his stroke.

12. A competitor, unless specially authorized by the Green Committee, shall not play with a professional, and he may not willingly receive advice from any one but his caddie, in any way whatever, under penalty of disqualification.

A forecaddie may be employed.

13. Competitors shall not discontinue play on account of bad weather, under penalty of disqualification.

14. Where, in the Rules of Golf, the penalty for the breach of any rule is the loss of the hole, in stroke competitions the penalty shall be the loss of two strokes, except where otherwise provided for in these Special Rules.

15. Any dispute regarding the play shall be determined by the Rules of Golf Committee.

16. The Rules of Golf, so far as they are not at variance with these Special Rules, shall apply to stroke competitions.

Etiquette of Golf.

1. A single player has no standing, and must always give way to a properly constituted match.

2. No player, caddie, or onlooker should move or talk during a stroke.

3. No player should play from the tee until the party in front have played their second strokes, and are out of range, nor play up to the putting-green till the party in front have holed out and moved away.

4. The player who has the honour should be allowed to play before his opponent tees his ball.

5. Players who have holed out should not try their putts over again when other players are following them.

6. Players looking for a lost ball must allow other matches coming up to pass them.

7. On request being made, a three-ball match must allow a single, threesome, or foursome to pass. Any match playing a whole round may claim the right to pass a match playing a shorter round.

8. If a match fail to keep its place on the green, and lose in distance more than one clear hole on those in front, it may be passed, on request being made.

9. Turf cut or displaced by a stroke should be at once replaced.

10. A player should carefully fill up all holes made by himself in a bunker.

11. It is the duty of an umpire or referee to take cognizance of any breach of rule that he may observe, whether he be appealed to on the point or not.

(H. G. H.)

Goltz, Kolmar von der, Baron (1843-——), Prussian soldier and military writer, was born at Bielkenfeld, East Prussia, on 12th August 1843, educated at the Cadet School at Kulm and Berlin, and received his commission in the infantry in 1861. In 1864 he entered the Berlin Military Academy, but was temporarily withdrawn in 1866 to serve in the Austrian war, in which he was wounded at Trautenau. In 1867 he joined the topographical division of the general staff, and at the beginning of the Franco-German war of 1870–71 was attached to the staff of Prince Frederick Charles. He took part in the battles of Mars-le-Tour and Gravelotte and in the siege of Metz. After its fall he served under the Red Prince in the campaign of the Loire against the French General Chanzy, including the battles of Orleans and Le Mans and the subsequent six days' fighting. He was appointed in 1871 professor at the Military School at Potsdam, and the same year was promoted captain and placed in charge of the historical division of the general staff. It was then he wrote *The Operations of the Second Army to the Capitulation of Metz*, and *The Seven Days of Le Mans*, both published in 1873. In 1874 he was appointed to the staff of the 6th division, and while so employed wrote *The Operations of the Second Army of the Loire*, and *Léon Gambetta and his Armies*, published in 1875 and 1877 respectively. The latter was translated into French the same year, and both are impartially written. In 1878 von der Goltz was appointed professor of military history at the Military Academy at Berlin, where he remained for five years, and attained the rank of major. He published, in 1883, *Rossbach and Jena* and *The Nation in Arms*, and during his residence in Berlin contributed many articles to the military journals. In June 1883 his services were lent to Turkey to organize the military educational establishments of the country, and he was made a pasha. On his return to Germany in 1896 he rose to be lieutenant-general, and was appointed commander of the 5th division in 1898, head of the Engineer and Pioneer Corps and inspector-general of fortifications. He has been a frequent contributor to military periodical literature, and, in addition to the works already named, has published *The Turco-Grecian War* and *The Conduct of War*, the latter of which has been translated into English.

Goluchowski, Agenor, Count (1849-——), Austrian statesman, was born in 1849. His father, descended from an old and noble Polish family, was governor of Galicia. Entering the diplomatic service, the son was in 1872 appointed attaché to the Austrian embassy at Berlin, where he became secretary of legation, and thence he was transferred to Paris. After rising to the rank of counsellor of legation, he was in 1887 made minister at Bucarest, where he remained till 1893. In these positions he acquired a great reputation as a firm and skilful diplomatist, and on the retirement of Count Kalnoky in May 1895 was chosen to succeed him as Austro-Hungarian minister for foreign affairs. In his speech of that year to the delegations he declared the maintenance of the Triple Alliance, and in particular the closest intimacy with Germany, to be the keystone of Austrian policy; at the same time he dwelt on the traditional friendship between Austria and Great Britain, and expressed his desire for a good understanding with all the Powers. In pursuance of this policy he effected an understanding with Russia, by which neither Power was to exert any separate influence in the Balkan peninsula, and thus removed a long-standing cause of friction. Austria's policy in the Balkans, to which he now secured the adhesion of Russia, was, in his words, "the

consolidation of the state of affairs created in the East by international treaties; the preservation of Turkey; the independence, strengthening, and free development of the several Balkan states, and of friendly relations with them; and, finally, the exclusion of the predominant influence of any single great Power to the detriment of the rest." This understanding was formally ratified during a visit to St Petersburg on which he accompanied the Emperor in April 1897. He took the lead in establishing the European Concert during the Armenian troubles of 1896, and again resisted isolated action on the part of any of the Great Powers during the Cretan troubles and the Greco-Turkish war. In November 1897, when the Austro-Hungarian flag was insulted at Mersina, he threatened to bombard the town if instant reparation were not made, and by his firm attitude greatly enhanced Austrian prestige in the East. In his speech to the delegations in 1898 he dwelt on the necessity of expanding Austria's mercantile marine, and of raising the fleet to a strength which, while not vying with the fleets of the great naval Powers, would ensure respect for the Austrian flag wherever her interests needed protection. He also hinted at the necessity for European combination to resist American competition. Count Goluchowski has devoted much of his energies to the problem of supervising emigration so that the loss of population may be compensated by the opening of new markets across the seas.

Gomel (*Homel*), a district town of Russia, 108 miles S.S.E. of Moghilev, on the Sozh, tributary of the Dnieper. It is an important junction of the railways from Wilno to Odessa, and Orel to Poland, and is in steamer communication with Kieff and Moghilev. It has gymnasia for boys and girls, and carries on a brisk trade in corn and timber; there are also paper-pulp mills and oil factories. Gomel was founded in the 12th century, and after changing hands several times between Poles and Russians, was annexed to Russia in 1772. Population (1897), 35,846, nearly half of whom are Jews.

Gomez, Maximo (1823——), Cuban soldier, was born in San Domingo in 1823. He entered the Spanish army in that island as a lieutenant, and rose to be captain. His family emigrated to Cuba and settled near Santiago. He joined the insurgent army in 1868, and obtained victories at Jiguani and Holguin in the following year. In 1872 the commander-in-chief, General Agramonte, promoted him to the rank of brigadier-general and sent him to command at Puerto Principe, where he increased his reputation. He captured Nuevitas, Santa Cruz, and Cascorra, and fought the battle of Las Guarimas. In 1874 he invaded the province of Santa Clara, defeated General Jovellar, and was made a major-general. On the collapse of the rebellion in 1878 he escaped to Jamaica, and lived as a farmer there and in San Domingo until the renewal of the rising in Cuba in 1895 under Jose Marti. He landed in Cuba on 14th April, and was made commander-in-chief of all the insurgent forces. Realizing the great strength of the Spanish forces in the island, he avoided serious encounters, and was content to hold areas of tropical wilderness by scattered squads, with a system of speedy dispersion and concentration. To this policy he added a systematic destruction of the two great Cuban industries—sugar and tobacco production—in order to impoverish the Spaniards and to compel the Cubans to take part in the war. The Spanish general, Campos, failed to make any head against the insurgents, and he was succeeded in February 1896 by Weyler, who strove to quell the rising by extreme severity. Early in 1896 a revolutionary government was formed under the presidency of Salvador Cisneros. In June Gomez defeated General Castillanos near Puerto Principe, and during 1897 he held the field. In October 1897 Weyler was recalled, and the new Spanish ministry under Señor Sagasta resolved to grant autonomy to Cuba, but the offer was rejected by the Cubans. Gomez by no means welcomed the intervention of the United States in 1898, and more than once attacked the President and Government in his public utterances. On the transfer of Cuba to the United States, however, on 1st January 1899, after the conclusion of the war with Spain, he accepted the terms offered him and promised to assist in disbanding the Cuban army. In consequence he was impeached on 12th March by the Cuban military assembly and removed from his command. On 7th April, however, he was reinstated by a majority of the Cuban generals, and he subsequently concluded the negotiations for the disbandment of the Cuban army with General Brooke, the United States military governor. (See CUBA.)

Goncharoff, Ivan Alexandrovich (1812–1891), Russian novelist, was born 6/18 July 1812, being the son of a rich merchant in the town of Simbirsk. At the age of ten he was placed in one of the gymnasiums at Moscow, from which he passed, though not without some difficulty on account of his ignorance of Greek, into the Moscow University. He read many French works of fiction, and published a translation of one of the novels of Eugène Sue. During his university career he devoted himself to study, taking no interest in the political and Socialistic agitation among his fellow-students. He was first employed as secretary to the governor of Simbirsk, and afterwards in the Ministry of Finance at St Petersburg. Being absorbed in bureaucratic work, Goncharoff paid no attention to the social questions then ardently discussed by such men as Herzen, Aksakoff, and Bielinski. He began his literary career by publishing translations from Schiller, Goethe, and English novelists. His first original work was *Obuiknovennaya Istoria*, "A Common Story" (1847). In 1856 he sailed to Japan as secretary to Admiral Putiatin for the purpose of negotiating a commercial treaty, and on his return to Russia he published a description of the voyage under the title of "The Frigate *Pallada*." His best work is *Oblomoff* (1857), which exposed the laziness and apathy of the smaller landed gentry in Russia anterior to the reforms of Alexander II. Russian critics have pronounced this work to be a faithful characterization of Russia and the Russians. Dobroluboff said of it, "Oblomofka [the country seat of the Oblomoffs] is our fatherland: something of Oblomoff is to be found in every one of us." Peesareff, another celebrated critic, declared that "Oblomoffism," as Goncharoff called the sum total of qualities with which he invested the hero of his story, "is an illness fostered by the nature of the Slavonic character and the life of Russian society." In 1858 Goncharoff was appointed a censor, and in 1868 he published another novel called *Obreev*. He was not a voluminous writer, and during the latter part of his life produced nothing of any importance. His death occurred on 15/27 September 1891. (G. D.)

Goncourt, de, the name of a famous French literary family. EDMOND DE GONCOURT was born at Nancy, 26th May 1822, and died at Champrosay, 16th July 1896. JULES DE GONCOURT, his brother, was born at Paris, 17th December 1830, and died at Paris, 20th June 1870. Writing always in collaboration, until the death of the younger, it was their ambition to be not merely novelists, inventing a new kind of novel, but historians; not merely historians, but the historians of a particular century, and of what was intimate and what is unknown in it; to be also discriminating, indeed innovating, critics

of art, but of a certain section of art, the 18th century, in France and Japan; and also to collect pictures and bibelots, always of the French and Japanese 18th century. Their histories (*Portraits intimes du xviii^e^ Siècle*, 1857, *La Femme au xviii^e^ Siècle*, 1862, *La du Barry*, 1878, &c.) are made entirely out of documents, autograph letters, scraps of costume, engravings, songs, the unconscious self-revelations of the time; their three volumes on *L'Art du xviii^e^ Siècle*, 1859–75, deal with Watteau and his followers in the same scrupulous, minutely enlightening way, with all the detail of unpublished documents; and when they came to write novels, it was with a similar attempt to give the inner, undiscovered, minute truths of contemporary existence, the *inédit* of life. The same morbidly sensitive noting of the *inédit*, of whatever came to them from their own sensations of things and people around them, gives its curious quality to the nine volumes of the *Journal*, 1887–96, which will remain, perhaps, the truest and most poignant chapter of human history that they have written. Their novels, *Sœur Philomène*, 1861, *Renée Mauperin*, 1864, *Germinie Lacerteux*, 1865, *Manette Salomon*, 1865, *Madame Gervaisais*, 1869, and, by Edmond alone, *La Fille Elisa*, 1878, *Les Frères Zemganno*, 1879, *La Faustin*, 1882, *Chérie*, 1884, are, however, the work by which they will live as artists. Learning something from Flaubert, and teaching almost everything to Zola, they invented a new kind of novel, and their novels are the result of a new vision of the world, in which the very element of sight is decomposed, as in a picture of Monet. Seen through the nerves, in this conscious abandonment to the tricks of the eyesight, the world becomes a thing of broken patterns, and conflicting colours, and uneasy movement. A novel of the Goncourts is made up of an infinite number of details, set side by side, every detail equally prominent. While a novel of Flaubert, for all its detail, gives above all things an impression of unity, a novel of the Goncourts deliberately dispenses with unity in order to give the sense of the passing of life, the heat and form of its moments as they pass. It is written in little chapters, sometimes no longer than a page, and each chapter is a separate notation of some significant event, some emotion or sensation which seems to throw sudden light on the picture of a soul. To the Goncourts humanity is as pictorial a thing as the world it moves in; they do not search further than "the physical basis of life," and they find everything that can be known of that unknown force written visibly upon the sudden faces of little incidents, little expressive moments. The soul, to them, is a series of moods, which succeed one another, certainly without any of the too arbitrary logic of the novelist who has conceived of character as a solid or consistent thing. Their novels are hardly stories at all, but picture-galleries, hung with pictures of the momentary aspects of the world. French critics have complained that the language of the Goncourts is no longer French, no longer the French of the past; and this is true. It is their distinction—the finest of their inventions—that, in order to render new sensations, a new vision of things, they invented a new language.

(A. Sy.)

Gonda, a town and district of British India, in the Fyzabad division of Oudh. The town is 28 miles north-west of Fyzabad, and is an important junction on the Bengal and North-Western Railway. The population in 1891 was 17,430; the municipal income in 1897–98 was Rs.16,334. The cantonments were abandoned in 1863. The DISTRICT OF GONDA has an area of 2880 square miles. Its population in 1881 was 1,270,926, and in 1891 was 1,459,229, giving an average density of 507 persons per square mile. In 1901 the population was 1,402,350, showing a decrease of 4 per cent. The land revenue and rates were Rs.16,83,221, the incidence of assessment per acre being R.1–6–4 on temporarily settled and R.0–13–11 on permanently settled land; the cultivated area in 1896–97 was 1,047,574 acres, of which 186,616 were irrigated from wells, tanks, &c.; the number of police was 2776; the number of vernacular schools in 1896–97 was 95, with 3873 pupils; the registered death-rate in 1897 was 42·67 per thousand. The district is traversed by the main line of the Bengal and North-Western Railway, with a branch from Gonda town towards Lucknow.

Gondal, a native state of India, within the Gujarat division of Bombay, situated in the centre of the peninsula of Kathiawar. Its area is 1024 square miles; population (1891), 161,036. The estimated gross revenue is about Rs.15,00,000, of which Rs.3,26,760 was expended in 1897–98 on public works; the tribute is Rs.1,10,721. The present chief, whose title is Thakor Saheb, is a Jareja Rajput, of the same clan as the Rao of Cutch. He was educated at the Rajkot college, and afterwards graduated in arts and medicine at the University of Edinburgh. He has published a book in English on the medical system of the Hindus. In 1898 he received the insignia of K.C.I.E. from Queen Victoria in person. The state has always been conspicuous for its progressive administration, and was recently raised from the second to the first class. It is traversed by a railway connecting it with Rajkot and with the sea-board. The TOWN OF GONDAL is 23 miles by rail south from Rajkot. It had in 1891 a population of 15,343. It has an Anglo-vernacular school, an iron foundry, and a state printing-press, issuing an official gazette.

Gooch, Sir Daniel, BART. (1816–1889), English mechanical engineer, was born at Bedlington, in Northumberland, on 16th August 1816. At the age of fifteen, having shown a taste for mechanics, he was put to work at the Tredegar Ironworks, Monmouthshire. In 1834 he went to Warrington, where, at the Vulcan foundry, under Robert Stephenson, he acquired the principles of locomotive design. Subsequently, after passing a year at Dundee, he was engaged by the Stephensons at their Gateshead works, where he seems to have conceived that predilection for the broad gauge for which he was afterwards distinguished, through having to design some engines for a 6-foot gauge in Russia and noticing the advantages it offered in allowing greater space for the machinery, &c., as compared with the standard gauge favoured by Stephenson. In 1837, on Brunel's recommendation, he was appointed locomotive superintendent to the Great Western Railway. When he accepted this post the engines possessed by the railway were very poor and inefficient; in fact, there were only about half-a-dozen that could be depended upon at all, and it was not an infrequent thing to send out one of the sounder ones to search for and help home a train which was more than usually unpunctual. Under Gooch, however, this state of affairs was soon remedied, and he gradually provided his employers with a stock of locomotives, many of which have scarcely even now been surpassed for general excellence and economy of working. One of the most famous, the *Lord of the Isles*, was awarded a gold medal at the Great Exhibition of 1851, and when thirty years afterwards it was withdrawn from active service it had run more than three-quarters of a million miles, all with its original boiler. In 1864 he left the Great Western and interested himself in the problem of laying a telegraph cable across the Atlantic. At this time Brunel's famous steamship, the *Great Eastern*, was in the hands of the bondholders, of whom he himself was one of the most important, and it occurred to him that she might advantageously be utilized in the enterprise. Accordingly, at his instance she was chartered by the Telegraph Construction

Company, of which also he was a director, and in 1865 was employed in the attempt to lay a cable, Gooch himself superintending operations. The cable, however, broke in mid-ocean, and the attempt was a failure. Next year it was renewed with more success, for not only was a new cable safely put in place, but the older one was picked up and spliced, so that there were two complete lines between England and America. For this achievement Gooch was created a baronet. Meanwhile the Great Western Railway had fallen on evil days, being indeed on the verge of bankruptcy when in 1866 the directors appealed to him to accept the chairmanship of the board and undertake the rehabilitation of the company. He agreed to the proposal, and was so successful in restoring its prosperity that in 1889, at the last meeting over which he presided, a dividend was declared at the rate of 7½ per cent. Under his administration the system was greatly enlarged and consolidated by the absorption of various smaller lines, such as the Bristol and Exeter and the Cornwall railways; and his appreciation of its strategic value caused him to be a strenuous supporter of the construction of the Severn Tunnel. His death occurred on 15th October 1889, at his residence, Clewer Park, near Windsor. (H. M. R.)

Goole, a market-town and port in the Osgoldcross parliamentary division of Yorkshire, England, at the confluence of the Don and the Ouse, 24 miles west by south of Hull by rail. Recent erections are a sailors' institute, court house, cottage hospital, post office, and market-hall. A new dock of 2½ acres was opened in 1882, and in 1891 one 620 feet long and 260 feet broad, with a depth of 22 feet. There are now in all eight docks supplied with timber ponds, quays, warehouses, and other accommodation. The registered shipping in 1888 consisted of 245 vessels of 24,787 tons; in 1899, 147 vessels of 26,391 tons. In 1888, 2258 vessels of 530,508 tons entered, and 2597 vessels of 661,616 tons cleared. In 1899, 2641 vessels of 853,440 tons entered, and 2756 vessels of 888,969 tons cleared. Area of urban district, 1441 acres. Population (1881), 10,418; (1901), 16,576.

Gorakhpur, a city, district, and division of the North-West Provinces of British India. The city is situated on the river Rapti, and had a population in 1881 of 57,922, and in 1901 of 63,409. The municipal income in 1897–98 was Rs.67,294; the registered death-rate in 1897 was 61·37 per thousand. It is the civil headquarters of the district, with a military cantonment, and has nine printing-presses, issuing one vernacular newspaper. The DISTRICT OF GORAKHPUR has an area of 4576 square miles. It had a population in 1881 of 2,617,120; in 1891 of 2,994,057, giving an average density of 654 persons per square mile; and in 1901 of 2,955,543, showing a decrease of 3 per cent. The land revenue and rates were Rs.31,59,359, the incidence of assessment being just under R.1 per acre; the cultivated area in 1896–97 was 1,905,024 acres, of which 531,183 were irrigated from wells, tanks, &c.; the number of police was 3263; the number of vernacular schools in 1896–97 was 202, with 9069 pupils; the registered death-rate in 1897 was 35·27 per thousand. The district is traversed by the main line of the Bengal and North-Western Railway, and both the Gogra and Rapti are navigable. There are twenty-eight indigo factories, employing 5500 persons, with an out-turn valued at Rs.3,00,000 per annum. The DIVISION has an area of 9491 square miles. The population in 1891 was 6,508,526, giving an average density of 685 persons per square mile, being more than one to every acre, and the highest for any large tract in India; in 1901 the population was 6,331,356, showing a decrease of 3 per cent.

Gorcum, or GORKUM (Dutch *Gorinchem*), a town in the Netherlands, province of South Holland, 22 miles E.S.E. of Rotterdam, near the influx of the Linge into the Merwede. Railway connexions have been established with Geldermalsum, Bois-le-Duc (1883), and Dordrecht (1885). Trade has also been promoted by the opening in 1894 of the Merwede Canal (Amsterdam–Gorcum). Gold and silver working are carried on. Population (1900), 11,855.

Gordium, an ancient city of Phrygia, situated on the Persian "Royal road" from Pessinus to Ancyra, and not far from the Sangarius. Ramsay identifies it with Yürme, Humann with Chakmak, and Crowfoot with Pebi.

Gordon, Adam Lindsay (1833–1870), Australian poet, was born at Fayal, in the Azores, in 1833, and was the son of a retired Indian officer who taught Hindostanee at Cheltenham College. A youthful indiscretion led to his being sent to South Australia in 1853 with a commission in the mounted police. Here for some years he prospered, married, and obtained a seat in the local parliament. Misfortune, nevertheless, overtook him, and in 1867 he removed to Victoria, where he published his poems. They brought him more praise than emolument, and, thoroughly discouraged, especially by his failure to make good his claim to some property in Scotland to which he believed himself entitled, he committed suicide at New Brighton on Port Phillip Bay on the 24th of June 1870. His reputation rose after his death, and he became the best known and most widely popular of Australian poets, although he must undoubtedly some day give place to one uniting to an equal or superior poetical talent a deeper feeling for Australian scenery and life. Much of Gordon's poetry might have been written in England: when, however, it is really local, it is vividly so; his genuine feeling frequently kindles into passion; his versification is always elastic and sonorous, but sometimes too reminiscent of Swinburne. His compositions are almost entirely lyrical, and their merit is usually in proportion to the degree in which they partake of the character of the ballad.

Gordon, Charles George (1833–1885), British soldier and administrator, fourth son of General H. W. Gordon, Royal Artillery, was born at Woolwich on 28th January 1833. He received his early education at Taunton school, and was given a cadetship in the Royal Military Academy, Woolwich, in 1848. He was commissioned as second lieutenant in the corps of Royal Engineers on 23rd June 1852. After passing through a course of instruction at the Royal Engineers' establishment, Chatham, he was promoted lieutenant in 1854, and was sent to Pembroke Dock to assist in the construction of the fortifications then being erected for the defence of Milford Haven. The Crimean war broke out shortly afterwards, and Gordon was ordered on active service, and landed at Balaclava on 1st January 1855. The siege of Sebastopol was in progress, and he had his full share of the arduous work in the trenches. He was attached to one of the British columns which assaulted the Redan on 18th June, and was also present at the capture of that work on 8th September. He took part in the expedition to Kinburn, and then returned to Sebastopol to superintend a portion of the demolition of the Russian dockyard. After peace with Russia had been concluded, Gordon was attached to an international commission appointed to delimit the new boundary, as fixed by treaty, between Russia and Turkey in Bessarabia; and on the conclusion of this work he was ordered to Asia Minor on similar duty, with reference to the eastern boundary between the two countries. While so employed

Gordon took the opportunity to make himself well acquainted with the geography and people of Armenia, and the knowledge of dealing with Eastern nations then gained was of great use to him in after life.

In China. He returned to England towards the end of 1858, and was then selected for the appointment of adjutant and field-works instructor at the Royal Engineers' establishment, and took up his new duties at Chatham after promotion to the rank of captain in April 1859. But his stay in England was brief, for in 1860 war was declared against China, and Gordon was ordered out there, arriving at Tientsin in September. He was too late for the attack on the Taku Forts, but was present at the occupation of Peking and destruction of the Summer Palace. He remained with the British force of occupation in Northern China until April 1862, when the British troops, under the command of General Staveley, proceeded to Shanghai, in order to protect the European settlement at that place from the Taeping rebels. The Taeping revolt, which had some remarkable points of similarity with the Mahdist rebellion in the Sudan, had commenced in 1850 in the province of Kwangsi. The leader, Hung Seu Tsuen, a semi-political, semi-religious enthusiast, assumed the title of Tien Wang, or Heavenly King, and by playing on the feelings of the lower class of people gradually collected a considerable force. The Chinese authorities endeavoured to arrest him, but the imperialist troops were defeated. The area of revolt extended northwards through the provinces of Hunan and Hupe, and down the valley of the Yang-tse-kiang as far as the great city of Nanking, which was captured by the rebels in 1853. Here the Tien Wang established his court, and while spending his own time in heavenly contemplation and earthly pleasures, sent the assistant Wangs on warlike expeditions through the adjacent provinces. For some years a constant struggle was maintained between the Chinese imperialist troops and the Taepings, with varying success on both sides. The latter gradually advanced eastwards, and approaching the important commercial city of Shanghai, alarmed the European inhabitants of that place, who subscribed to raise a mixed force of Europeans and Manila men for the defence of the town. This force, which was placed under the command of an American named Ward, took up a position in the country west of Shanghai to check the advance of the rebels. Fighting continued round Shanghai for about two years, but Ward's force was not altogether successful, and when General Staveley arrived from Tientsin affairs were in a somewhat critical condition. He decided to clear the district of rebels within a radius of 30 miles from Shanghai, and Gordon was attached to his staff as engineer officer. A French force, under the command of Admiral Prôtet, co-operated with Staveley, and Ward, with his little army, also assisted. Kahding, Singpo, and other towns were occupied, and the country was fairly cleared of rebels by the end of 1862. Ward was, unfortunately, killed in the assault of Tseki, and his successor, Burgevine, having had a quarrel with the Chinese authorities, Li Hung Chang, the governor of the Kiang-su province, requested General Staveley to appoint a British officer to command the contingent. Staveley selected Gordon, who had been made a brevet-major in December 1862 for his previous services, and the nomination was approved by the British Government. The choice was judicious, as further events proved. In March 1863 Gordon proceeded to Sungkiang to take command of the force, which had received the name of "The Ever-Victorious Army," an encouraging though somewhat exaggerated title, considering its previous history. Without waiting to reorganize his troops he marched at once to the relief of Chansu, a town 40 miles north-west of Shanghai, which was invested by the rebels. The relief was successfully accomplished, and the operation established Gordon in the confidence of his troops. He then reorganized his force, a matter of no small difficulty, and advanced against Quinsan, which was captured, though with considerable loss. Gordon then marched through the country, seizing town after town from the rebels, until at length the great city of Suchow was invested by his army and a body of Chinese imperialist troops. The city was taken on the 29th of November, and after its capture Gordon had a serious dispute with Li Hung Chang, as the latter had beheaded certain of the rebel leaders whose lives the former had promised to spare if they surrendered. This action, though not opposed to Chinese ethics, was so opposed to Gordon's ideas of honour, that he withdrew his force from Suchow, and remained inactive at Quinsan until February 1864. He then came to the conclusion that the subjugation of the rebels was more important than his dispute with Li, and visited the latter in order to arrange for further operations. By mutual consent no allusion was made to the death of the Wangs. This was a good example of one of Gordon's marked characteristics, that, though a man of strong personal feelings, he was always prepared to subdue them for the public benefit. He declined, however, to take any decoration or reward from the emperor for his services at the capture of Suchow. After the meeting with Li Hung Chang the "Ever-Victorious Army" again advanced and took a number of towns from the rebels, ending with Chanchufu, the principal military position of the Taepings. This fell in May, when Gordon returned to Quinsan and disbanded his force. In June the Tien Wang, seeing his cause was hopeless, committed suicide, and the capture of Nanking by the imperialist troops shortly afterwards brought the Taeping revolt to a

General Gordon.
(From a photograph by the London Stereoscopic Company.)

conclusion. The suppression of this serious movement was undoubtedly due in great part to the skill and energy of Gordon, who had shown remarkable qualities as a leader of men. The emperor promoted him to the rank of Titu, the highest grade in the Chinese army, and also gave him the Yellow Jacket, the most important decoration in China. He wished to give him a large sum of money, but this Gordon refused. He was promoted lieutenant-colonel for his Chinese services, and made a Companion of the Bath. Henceforth he was often familiarly spoken of as "Chinese" Gordon.

Gordon was appointed on his return to England Commanding Royal Engineer at Gravesend, where he was employed in superintending the erection of forts for the defence of the Thames. He devoted himself with energy to his official duties, and his leisure hours to practical philanthropy. All the acts of kindness which he did for the poor during the six years he was stationed at Gravesend will never be fully known. In October 1871 he was appointed British representative on the international commission which had been constituted after the Crimean war to maintain the navigation of the mouth of the river Danube, with headquarters at Galatz. During 1872 Gordon was sent to inspect the British military cemeteries in the Crimea, and when passing through Constantinople on his return to Galatz he made the acquaintance of Nubar Pasha, prime minister of Egypt, who sounded him as to whether he would take service under the Khedive. Nothing further was settled at the time, but the following year he received a definite offer from the Khedive, which he accepted with the consent of the British Government, and proceeded to Egypt early in 1874. He was then a colonel in the army, though still only a captain in the corps of Royal Engineers.

In the Egyptian Sudan.

To understand the object of the appointment which Gordon accepted in Egypt, it is necessary to give a few facts with reference to the Sudan. That vast territory, bordering the Nile on both sides from the Egyptian frontier to the equator, after a long and varied history, had lapsed into a state of semi-barbarism. Mehemet Ali, the ruler of Egypt, having made himself practically independent of his suzerain, the Sultan of Turkey, conceived the project of founding an African empire, and with this object determined to take possession of the Sudan. An expedition was sent up the Nile in 1820 under the command of Ismail, son of Mehemet Ali. The force reached Khartum after meeting with considerable opposition, and the province of Sennaar was captured, but in 1822 Ismail was murdered by the inhabitants of Shendy near Berber. Notwithstanding this, the Egyptians pressed southwards and conquered Kordofan and Fazogl. In 1865 Turkey ceded the province of Suakin and Massawa on the Red Sea to the Khedive, thus rounding off the possessions of Egypt in the Sudan. One result of the Egyptian occupation of the country was that the slave trade was largely developed, especially in the White Nile and Bahr-el-Ghazal districts. Captains Speke and Grant, who had travelled through Uganda and came down the White Nile in 1863, and Sir Samuel Baker, who went up the same river as far as Albert Nyanza, brought back harrowing tales of the misery caused by the slave-hunters. Public opinion was considerably moved, and in 1869 the Khedive Ismail decided to send an expedition up the White Nile, with the double object of limiting the evils of the slave trade and opening up the district to commerce. The command of the expedition was given to Sir Samuel Baker, who reached Khartum in February 1870, but, owing to the obstruction of the river by the sudd or grass barrier, did not reach Gondokoro, the centre of his province, for fourteen months. He met with great difficulties, and when his four years' service came to an end little had been effected beyond establishing a few posts along the Nile and placing some steamers on the river. It was to succeed Baker as governor of the White Nile province that the Khedive asked for Gordon's services, having come to the conclusion that the latter was the most likely person to bring the affair to a satisfactory conclusion. After a short stay in Cairo, Gordon proceeded to Khartum by way of Suakin and Berber, a route which he ever afterwards regarded as the best mode of access to the Sudan. From Khartum he proceeded up the White Nile to Gondokoro, where he arrived in twenty-four days, the sudd, which had proved such an obstacle to Baker, having been removed since the departure of the latter by the Egyptian governor-general. Gordon remained in the Equatorial Provinces until October 1876, and then returned to Cairo. The two years and a half thus spent in Central Africa was a time of incessant toil. A line of stations was established from Sobat on the White Nile to the frontier of Uganda, and considerable progress was made in the suppression of the slave trade. The river and Lake Albert were mapped by Gordon and his staff, and he devoted himself with wonted energy to improving the condition of the people. Greater results might have been obtained but for the fact that Khartum and the whole of the Sudan north of the Sobat were in the hands of an Egyptian governor, independent of Gordon, and not too well disposed towards his proposals for diminishing the slave trade. On arriving in Cairo Gordon informed the Khedive of his reasons for not wishing to return to the Sudan, but did not definitely resign the appointment of governor of the Equatorial Provinces. But on reaching London he telegraphed to the British consul-general in Cairo, asking him to let the Khedive know that he would not go back to Egypt. Ismail Pasha, feeling, no doubt, that Gordon's resignation would injure his prestige, wrote to him saying that he had promised to return, and that he expected him to keep his word. Upon this Gordon, to whom the keeping of a promise was a sacred duty, decided to return to Cairo, but gave an assurance to some friends that he would not go back to the Sudan unless he was appointed governor-general of the entire province. After some discussion the Khedive agreed, and made him governor-general of the Sudan, inclusive of Darfur and the Equatorial Provinces.

Governor-General.

One of the most important questions which Gordon had to take up on his appointment was the state of the political relations between Egypt and Abyssinia, which had been in an unsatisfactory condition for some years. The dispute centred round the district of Bogos, lying not far inland from Massawa, which both the Khedive and King John of Abyssinia claimed as belonging to their respective dominions. War broke out in 1875, when an Egyptian expedition was despatched to Abyssinia, and was completely defeated by King John near Gundet. A second and larger expedition, under Prince Hassan, the son of the Khedive, was sent the following year from Massawa. The force was routed by the Abyssinians at Gura, but Prince Hassan and his staff got back to Massawa. Matters then remained quiet until March 1877, when Gordon proceeded to Massawa to endeavour to make peace with King John. He went up to Bogos, and had an interview with Wadenkal, an Abyssinian chief, who had joined the Egyptians with a view to raiding on his own account. Gordon, with his usual powers of diplomacy, persuaded Wadenkal to remain quiet, and wrote to the king proposing terms of peace. But he received no reply at that time, as John, feeling pretty secure on the

Egyptian frontier after his two successful actions against the Khedive's troops, had gone southwards to fight with Menelek, king of Shoa. Gordon, seeing that the Abyssinian difficulty could wait for a few months, proceeded to Khartum. Here he took up the slavery question, and proposed to issue regulations making the registration of slaves compulsory, but his proposals were not approved by the Cairo Government. In the meantime an insurrection had broken out in Darfur, and Gordon proceeded to that province to relieve the Egyptian garrisons, which were considerably stronger than the force he had available, the insurgents also being far more numerous than his little army. On coming up with the main body of rebels he saw that diplomacy gave a better chance of success than fighting, and, accompanied only by an interpreter, rode into the enemy's camp to discuss the situation. This bold move, which probably no one but Gordon would have attempted, proved quite successful, as part of the insurgents joined him, and the remainder retreated to the south. The relief of the Egyptian garrisons was successfully accomplished, and Gordon visited the provinces of Berber and Dongola, whence he had again to return to the Abyssinian frontier to treat with King John. But no satisfactory settlement was arrived at, and Gordon came back to Khartum in January 1878. There he had scarcely a week's rest when the Khedive summoned him to Cairo to assist in settling the financial affairs of Egypt. He reached Cairo in March, and was at once appointed by Ismail as president of a commission of inquiry into the finances, on the understanding that the European commissioners of the debt, who were the representatives of the bondholders, and whom Ismail regarded as interested parties, should *not* be members of the commission. Gordon accepted the post on these terms, but the consuls-general of the different Powers refused to agree to the constitution of the commission, and it fell to the ground, as the Khedive was not strong enough to carry his point. The attempt of the latter to utilize Gordon as a counterpoise to the European financiers having failed, Ismail fell into the hands of his creditors, and was deposed by the Sultan in the following year in favour of his son Tewfik. After the conclusion of the financial episode, Gordon proceeded to the province of Harrar, south of Abyssinia, and, finding the administration in a bad condition, dismissed Raouf Pasha, the governor. He then returned to Khartum, and in 1879 went again into Darfur to pursue the slave traders, while his subordinate, Gessi Pasha, fought them with great success in the Bahr-el-Ghazal district and killed Suleiman, the leader. This put an end to the revolt, and Gordon went back to Khartum. Shortly afterwards he went down to Cairo, and when there was requested by the new Khedive to pay a visit to King John and make a definite treaty of peace with Abyssinia. Gordon had an interesting interview with the king, but was not able to do much, as the king wanted great concessions from Egypt, and the Khedive's instructions were that nothing material was to be conceded. The matter ended by Gordon being made a prisoner and sent back to Massawa. Thence he returned to Cairo and resigned his Sudan appointment. He was considerably exhausted by the three years' incessant work, during which he had ridden no less than 8500 miles on camels and mules, and was constantly engaged in the task of trying to reform a vicious system of administration.

In March 1880 Gordon visited the king of the Belgians at Brussels, and King Leopold suggested that he should at some future date take charge of the Congo Free State. In April the Government of the Cape Colony telegraphed to him offering the position of commandant of the Cape local forces, but he declined the appointment. In May the Marquis of Ripon, who had been given the post of Governor-General of India, asked Gordon to go with him as private secretary. This he agreed to do, but a few days later, feeling that he was not suitable for the position, asked Lord Ripon to release him. *1880-1884.*
The latter refused to do so, and Gordon accompanied him to India, but definitely resigned his post on Lord Ripon's staff shortly afterwards. Hardly had he resigned when he received a telegram from Sir Robert Hart, inspector-general of customs in China, inviting him to go to Peking. He started at once, and arrived at Tientsin in July, where he met Li Hung Chang, and learnt that affairs were in a critical condition, and that there was risk of war with Russia. Gordon proceeded to Peking and used all his influence in favour of peace. His arguments, which were given with much plainness of speech, appear to have convinced the Chinese Government, and war was avoided. Gordon returned to England, and in April 1881 exchanged with a brother officer, who had been ordered to Mauritius as Commanding Royal Engineer, but who for family reasons was unable to accept the appointment. He remained in Mauritius until the March following, when, on promotion to the rank of major-general, he had to vacate the position of Commanding Royal Engineer. Just at the same time the premier of Cape Colony telegraphed to him to ask if he would go to the Cape to consult with the Government as regards settling affairs in Basutoland. The telegram stated that the position of matters was grave, and that it was of the utmost importance that the colony should secure the services of some one of proved ability, firmness, and energy. Gordon sailed at once for the Cape, and saw the governor, Sir Hercules Robinson, and the premier, Mr Merriman, who, for political reasons, asked him not to go to Basutoland, but to take the appointment of commandant of the colonial forces at King William's Town. After a few months, which were spent in reorganizing the colonial forces, Gordon was requested to go up to Basutoland to try to arrange a settlement with the chief Masupha, one of the most powerful of the Basuto leaders. Greatly to his surprise, at the very time he was with Masupha a member of the Cape Government was taking steps to induce Lerethodi, another chief, to advance against Masupha. This not only placed Gordon in a position of danger, but was regarded by him as an act of treachery. He advised Masupha not to deal with the Cape Government until the hostile force was withdrawn, and resigned his appointment. He considered that the Basuto difficulty was due to the bad system of administration by the Cape Government. That Gordon's views were correct is proved by the fact that a few years later Basutoland was separated from Cape Colony and placed directly under the Imperial Government. After his return to England from the Cape, being unemployed, Gordon decided to go to Palestine, a country he had long desired to visit. Here he remained for a year, and devoted his time to the study of Biblical history and of the antiquities of Jerusalem. The king of the Belgians then asked him to take charge of the Congo Free State, and he accepted the mission, and returned to London to make the necessary preparations. But a few days after his arrival he was requested by the British Government to proceed immediately to the Sudan. To understand the reasons for this, it is necessary briefly to recapitulate the course of events in that country since Gordon had left it in 1879.

After his resignation of the post of governor-general, Raouf Pasha, an official of the ordinary type, who, as already mentioned, had been dismissed by Gordon for misgovernment in 1878, was appointed to succeed him.

As Raouf was instructed to increase the receipts and diminish the expenditure, the system of government naturally reverted to the old methods, which Gordon had endeavoured to improve. The fact that justice and firmness were succeeded by injustice and weakness tended naturally to the outbreak of revolt, and unfortunately there was a leader ready to head a rebellion—one Mahommed Ahmed, already known for some years as a holy man, who was insulted by an Egyptian official, and retiring with some followers to the island of Abba on the Nile, proclaimed himself as the Mahdi, a successor of the Prophet. Raouf endeavoured to take him prisoner, but without success, and the revolt spread rapidly. Raouf was recalled, and succeeded by Abdel Kader Pasha, a much stronger governor, who had some success, but whose forces were quite insufficient to cope with the rebels. The Egyptian Government was too busily engaged in suppressing Arabi's revolt to be able to send any help to Abdel Kader, and in September 1882, when the British troops entered Cairo, the position in the Sudan was very perilous. Had the British Government listened to the representations then made to them that, having conquered Egypt, it was imperative at once to suppress the revolt in the southern provinces, the rebellion could have been crushed, but unfortunately Great Britain would neither take effective steps herself nor allow Egypt to do so. It is unnecessary to follow the sad history. Suffice it to say that in December 1883 the British Government saw that something must be done, and ordered Egypt to abandon the Sudan. But abandonment was a policy most difficult to carry out, as it involved the withdrawal of thousands of Egyptian employés and their families. Abdel Kader Pasha was asked to undertake the work, and he agreed on the understanding that he would be supported, and that the policy of abandonment was not to be announced. But the latter condition was refused, and he declined the task. The British Government then asked General Gordon to proceed to Khartum to report on the best method of carrying out the evacuation. He received his instructions on the 18th of January 1884, and started at once for Cairo, accompanied by Lieut.-Colonel Stewart.

At Khartum.

At Cairo he received further instructions from the British minister, Sir Evelyn Baring, and was appointed by the Khedive as governor-general, with full powers. Travelling by Korosko and Berber, he arrived at Khartum on the 18th of February, and was well received by the inhabitants, who believed that he had come to save the country from the rebels. Gordon at once commenced the task of sending the women and children and the sick and wounded to Egypt, and about two thousand five hundred had been removed before the Mahdi's forces closed upon Khartum. At the same time he considered what was the best arrangement for the future government of the country, and decided that the only possible man was Zobeir Pasha, who had formerly had great influence in the Sudan, and had been detained in Cairo for some years. But the British Government refused to sanction the appointment, because Zobeir had been a slave-dealer. The advance of the rebels against Khartum was combined with a revolt in the Eastern Sudan, and the Egyptian troops in the vicinity of Suakin met with constant defeat. At length a British force was sent to Suakin under the command of General Sir Gerald Graham, and routed the rebels in several hard-fought actions. Gordon telegraphed to Sir Evelyn Baring urging that the road from Suakin to Berber should be opened by a small force. But this request, though strongly supported by Baring and the British military authorities in Cairo, was refused by the Government in London. In April General Graham and his forces were withdrawn from Suakin, and Gordon and the Sudan were definitely abandoned to their fate. The garrison of Berber, seeing that there was no chance of relief, surrendered a month later, and Khartum was completely isolated. Had it not been for the presence of Gordon the city would also soon have fallen, but with an energy and skill that were almost miraculous, he so organized the defence that Khartum held out until January 1885. When it is remembered that Gordon was of a different nationality and religion to the garrison and population, that he had only one British officer to assist him, and that the town was badly fortified and insufficiently provided with food, it is just to say that the defence of Khartum is one of the most remarkable episodes in military history. The siege commenced on the 18th of March, but it was not until August that the British Government decided to take steps to relieve Gordon. General Stephenson, who was in command of the British troops in Egypt, wished to send a brigade at once to Dongola, but he was overruled, and it was not until the beginning of November that the British relief force was ready to start from Wadi Halfa under the command of Lord Wolseley. The force reached Korti towards the end of December, and from that place a column was despatched across the Bayuda desert to Metemmeh on the Nile. After some severe fighting, in which the leader of the column, Sir Herbert Stewart, was mortally wounded, the force reached the river on the 20th of January, and the following day four steamers, which had been sent down by Gordon to meet the British advance, and which had been waiting for them for four months, reported to Sir Charles Wilson, who had taken command after Sir Herbert Stewart was wounded.

Death.

On the 24th Wilson started with two of the steamers for Khartum, but on arriving there on the 28th he found that the place had been captured by the rebels and Gordon killed two days before. At one time there was an idea current that Wilson might have started earlier and saved the town, but this was quite groundless. In the first place, Wilson could not have started sooner than he did; and in the second, even if he had been able to do so, it would have made no difference, as the rebels could have taken Khartum any time they pleased after the 5th of January, when the provisions were exhausted. Another popular notion, that the capture of the place was due to treachery on the part of the garrison, is equally without foundation. The attack was made at a point in the fortifications where the rampart and ditch had been destroyed by the rising of the Nile, and when the Mahdi's troops entered the soldiers were too weak to make any effectual resistance. Gordon himself expected the town to fall before the end of December, and it is really difficult to understand how he succeeded in holding out until the 26th of January. Writing on the 14th of December he said, "Now, mark this, if the expeditionary force—and I ask for no more than two hundred men—does not come in ten days, the town may fall, and I have done my best for the honour of my country." He had indeed done his best, and far more than could have been regarded as possible. To understand what he went through during the latter months of the siegè, it is only necessary to read his own Journal, a portion of which, dating from 10th September to 14th December 1884, was fortunately preserved and published.

Gordon was not an author, but he wrote many short memoranda on subjects that interested him, and a considerable number of these have been utilized, especially in the work by his brother, Sir Henry Gordon, entitled *Events in the Life of Charles George Gordon, from its Beginning to its End.* He was a voluminous letter writer,

and much of his correspondence has been published. His character was remarkable, and the influence he had over those with whom he came in contact was very striking. His power to command men of non-European races was probably unique. He had no fear of death, and cared but little for the opinion of others, adhering tenaciously to the course be believed to be right in the face of all opposition. Though not holding to outward forms of religion, he was a truly religious man in the highest sense of the word, and was a constant student of the Bible. To serve God and to do his duty were the great objects of his life, and he died as he had lived, carrying out the work that lay before him to the best of his ability. The last words of his last letter to his sister, written when he knew that death was very near, sum up his character: "I am quite happy, thank God, and, like Lawrence, I have *tried* to do my duty."

Görgei, Arthur (1818–——), Hungarian soldier, was born at Toporcz, in Upper Hungary, on the 5th of February 1818. He came of a Saxon patrician family, who were converts to Protestantism. As befitting his rank, he entered in 1837 the Bodyguard of Hungarian Nobles at Vienna, where he combined military service with a course of study at the University. In 1845, on the death of his father, he retired from the army and devoted himself to the study of chemistry at Prague. On the outbreak of the revolutionary war of 1848, Görgei offered his sword to the Hungarian Government. Entering the Honvéd army with the rank of captain, he was almost immediately given the command of the National Garde Mobile north of the Theiss. Whilst he was engaged in preventing the Croatian army from crossing the Danube, at the island of Csepel, below Pesth, the wealthy Hungarian magnate Count Eugene Zichy fell into his hands, and Görgei executed summary justice upon the unfortunate noble, who, being arraigned before a court-martial on a charge of treason, was immediately hanged. After various successes over the Croatian forces, Görgei was appointed commander of the army of the Upper Danube, but, on the advance of Prince Windischgrätz across the Leitha, he retreated, in spite of the remonstrances of Kossuth, upon Waitzen. Here, irritated by what he considered undue interference with his plans, he issued a proclamation throwing the blame for the recent want of success upon the Government, and virtually revolting against their authority. Görgei retired to the Hungarian Erzgebirge and conducted operations on his own initiative. Meanwhile, the supreme command had been conferred upon the Pole, Dembinski, but the latter suffered defeat at Kapolna, and the command again devolved upon Görgei. The campaign in the spring of 1849 was brilliantly conducted by him, and in a series of engagements he defeated Windischgrätz at Izsaszeg and Wohlgemuth at Nagy Sarló; had he followed up his successes by taking the offensive against the Austrian frontier, it is quite possible that he might have dictated terms in the Austrian capital itself. As it was, he contented himself with reducing Ofen, and then he remained inactive for some weeks. Meanwhile, at a Diet held at Debreczin, Kossuth had formally proposed the dethronement of the Hapsburg dynasty, and Hungary had been proclaimed a republic. Görgei, who had refused the field-marshal's baton offered him by Kossuth, now accepted under the new Government the portfolio of Minister of War, while retaining the command of the troops in the field. The Russians had, however, intervened in the struggle and made common cause with the Austrians; they were advancing into Hungary on all sides, and Görgei was defeated by Haynau at Pered. Kossuth perceiving the impossibility of continuing the struggle, and being unwilling himself to make terms, resigned his position as dictator, and was succeeded by Görgei, who, with his army of 20,000 infantry and 2000 cavalry, surrendered to the Russian general Rüdinger at Vilagos. Görgei was not court-martialled, as were his captains, but kept in confinement at Klagenfurt, where he lived until 1867, when he was pardoned, and returned to Hungary. Since then he has not played any rôle in public life, and though in 1885 an attempt was made to rehabilitate him in public estimation, it was not favourably entertained in Hungary. (See also article HUNGARY, *History*, in *Ency. Brit.*, 9th edition.)

Gori, district town of Russia, Transcaucasia, government and 49 miles by rail N.W. of Tiflis, on the Kura; altitude 2000 feet. The surrounding country is very picturesque, the climate very mild, and Gori is one of the best smaller towns of Transcaucasia. It has a high school for girls, and a school for Russian and Tatar teachers. Gori is built at the foot of the hill upon which stood the Goristsikhe fortress, founded, according to tradition, by Byzantine emperors. It was founded probably in the 7th century, and rebuilt in 1123. Population (1897), 10,457.

Gorlice, a district town in South-Western Galicia, Austria, on the Ropa river. It is an old and important trading centre for corn, wine, linen, and woollen stuffs, and other local products, such as the naphtha distilled from the asphalt, of which there are large deposits in the vicinity. Population (1890), 5653; (1900), 6458.

Görlitz, a town of Prussia, province of Silesia, 66 miles east of Dresden by rail, on the Neisse. It is an important industrial town and railway centre, and ranks as the second town in Silesia. In 1889–91 a tower (276 feet) was built to the church of St Peter and St Paul. The town, which has grown rapidly since the demolition of the former walls, has a handsome appearance, and is adorned with statues to the Emperor William I. (1893), Burgomaster Demiani by Schilling (1876), and (in the town park) to Böhme (1898), Prince Frederick Charles (1891), the War of Liberation of 1813, and (in the town) a monument of Roon (1895) and an ornamental fountain (1887). The neighbouring hill of Landeskrone (1410 feet) is adorned with a monumental obelisk to Theodor Körner (1896). Amongst the public institutions may be mentioned the Milich Library and the library of the Upper Lusatia Society—both containing valuable MSS.—the municipal museum of Lusatian antiquities, the Emperor William Museum, commercial, agricultural, industrial, and other special schools, and the railway bridge (1650 feet long), of 32 arches, across the river Neisse. Görlitz is regarded as classic ground for the study of German Renaissance architecture. It also plays a prominent part in the musical world of Silesia. In addition to nearly a

dozen large cloth factories, employing over 2000 hands each, there are factories for the manufacture of alpaca, machinery, gold and silver wares, wirework, chemicals, sausages, railway material, and toys. Population (1885), 55,702; (1900), 80,932.

Gortchakoff, Alexander Michailovitch, PRINCE (1798–1883), Russian statesman, came of a princely family which claimed descent from Rurik. He was born on the 16th of July 1798, and was educated at the lyceum of Tsarskoe Selo, where he had the poet Pushkin as a school-fellow. He became a good classical scholar, and learnt to speak and write in French with facility and elegance. Pushkin in one of his poems described young Gortchakoff as "Fortune's favoured son," and predicted his success. On leaving the lyceum Gortchakoff entered the Foreign Office under Count Nesselrode. His first diplomatic work of importance was the negotiation of a marriage between the Grand Duchess Olga and the Crown Prince Charles of Würtemberg. He remained at Stuttgart for some years as Russian minister and confidential adviser of the Crown Princess. He foretold the outbreak of the revolutionary spirit in Germany and Austria, and was credited with counselling the abdication of Ferdinand in favour of Francis Joseph. When the German confederation was re-established in 1850 in place of the parliament of Frankfort, Gortchakoff was appointed Russian minister to the Diet. It was here that he first met Prince Bismarck, with whom he formed a friendship which was afterwards renewed at St Petersburg. The Emperor Nicholas found that his ambassador at Vienna, Baron Meyendorff, was not a sympathetic instrument for carrying out his schemes in the East. He therefore transferred Gortchakoff to Vienna, where the latter remained through the critical period of the Crimean war. Gortchakoff perceived that Russian designs against Turkey, supported by Great Britain and France, were impracticable, and he counselled Russia to make no more useless sacrifices, but to accept the bases of a pacification. At the same time, although he attended the Paris Conference of 1856, he purposely abstained from affixing his signature to the treaty of peace after that of Count Orloff, Russia's chief representative. For the time, however, he made a virtue of necessity, and Alexander II., recognizing the wisdom and courage which Gortchakoff had exhibited, appointed him minister of foreign affairs in place of Count Nesselrode. Not long after his accession to office Gortchakoff issued a circular to the foreign Powers, in which he announced that Russia proposed, for internal reasons, to keep herself as free as possible from complications abroad, and he added the now historic phrase, "*La Russie ne boude pas; elle se recueille.*" During the Polish insurrection Gortchakoff rebuffed the suggestions of Great Britain, Austria, and France for assuaging the severities employed in quelling it, and he was especially acrid in his replies to Earl Russell's despatches. In July 1863 Gortchakoff was appointed chancellor of the Russian empire expressly in reward for his bold diplomatic attitude towards an indignant Europe. The appointment was hailed with enthusiasm in Russia, and at that juncture Prince Chancellor Gortchakoff was unquestionably the most powerful minister in Europe.

An *approchement* now began between the courts of Russia and Prussia; and in 1863 Gortchakoff smoothed the way for the occupation of Holstein by the Federal troops. This seemed equally favourable to Austria and Prussia, but it was the latter Power which gained all the substantial advantages; and when the conflict arose between Austria and Prussia in 1866, Russia remained neutral and permitted Prussia to reap the fruits and establish her supremacy in Germany. When the Franco-German war of 1870–71 broke out Russia answered for the neutrality of Austria. An attempt was made to form an anti-Prussian coalition, but it failed in consequence of the cordial understanding between the German and Russian chancellors. In return for Russia's service in preventing the aid of Austria from being given to France, Gortchakoff looked to Bismarck for diplomatic support in the Eastern Question, and he received an instalment of the expected support when he successfully denounced the Black Sea clauses of the Treaty of Paris. This was justly regarded by him as an important service to his country and one of the triumphs of his career, and he hoped to obtain further successes with the assistance of Germany, but the cordial relations between the cabinets of St Petersburg and Berlin did not subsist much longer. In 1875 Bismarck was suspected of a design of again attacking France, and Gortchakoff gave him to understand, in a way which was not meant to be offensive, but which roused the German chancellor's indignation, that Russia would oppose any such scheme. The tension thus produced between the two statesmen was increased by the political complications of 1875–78 in South-Eastern Europe, which began with the Herzegovinian insurrection and culminated at the Berlin Congress. Gortchakoff hoped to utilize the complications in such a way as to recover, without war, the portion of Bessarabia ceded by the Treaty of Paris, but he soon lost control of events, and the Slavophil agitation produced the Russo-Turkish campaign of 1877–78. By the preliminary peace of San Stefano the Slavophil aspirations seemed to be realized, but the stipulations of that peace were considerably modified by the Congress of Berlin (13th June to 13th July 1878), at which the aged chancellor held nominally the post of first plenipotentiary, but left to the second plenipotentiary, Count Schuvaloff, not only the task of defending Russian interests, but also the responsibility and odium for the concessions which Russia had to make to Great Britain and Austria. He had the satisfaction of seeing the lost portion of Bessarabia restored to his country by the Berlin Treaty, but at the cost of greater sacrifices than he anticipated. After the congress he continued to hold the post of minister for foreign affairs, but lived chiefly abroad, and resigned formally in 1882, when he was succeeded by M. de Giers. He died at Baden-Baden on the 11th of March 1883. Prince Gortchakoff devoted himself entirely to foreign affairs, and took no part in the great internal reforms of Alexander II.'s reign. As a diplomatist he displayed many brilliant qualities—adroitness in negotiation, incisiveness in argument, and elegance in style. His statesmanship, though marred occasionally by personal vanity and love of popular applause, was far-seeing and prudent. In the latter part of his career his main object was to raise the prestige of Russia by undoing the results of the Crimean war, and it may fairly be said that he in great measure succeeded.

Görz and **Gradisca,** a county and crownland of the Cisleithan half of the Austro-Hungarian Monarchy. In conjunction with the peninsula and islands of Istria, and the town and territory of Trieste, they constitute the Austro-Illyrian Küstenland or littoral. Gradisca is that part of Friuli which remained to Austria after the peace of Nikolsburg in 1866. Population (1880), 211,084; (1900), 232,338. Racially 63 per cent. are Slovenes, 36 per cent. Italians and Ladins, *i.e.*, Friulians who speak the Ladin dialect, and 1 per cent. German. Classified by religions, 99·6 per cent. are Roman Catholic, the remainder being of the Hebrew, Protestant, and Greek Orthodox faiths. In 1896 the marriage-rate was 6·75, the birth-rate

36·40, or, excluding still-births, 35·42, and the death-rate 26·01 per thousand. Of the births 3·38 per cent. were illegitimate, the lowest proportion in Austria. The crownland is represented in the Reichsrath by five members (three Italians and two Slovenes). The provincial Diet is composed of twenty-one Italians and twelve Slovenes. Although 70·47 per cent. of the population is still engaged in agriculture and forestry, industry (17·65 per cent.) is progressing, and particularly the manufacture of silk, of which the chief seats are the town of Görz and the village of Haidenschaft. Viticulture and the cultivation of the silk-worm are the chief agricultural resources. The most important crops are maize, wheat, buckwheat, barley, potatoes, and fruit. A small quantity of rice is also grown. For education, communications, &c., see KÜSTENLAND.

Görz (Italian, *Gorizia*), chief town of the Austrian crownland and administrative district of the same name. Industry is progressing, particularly the manufacture of silk and cotton yarns and stuffs, candles, liqueurs, &c. The principal trade is in early fruit, grapes, and vegetables. The entertainment of visitors is a resource of growing importance, owing to the increasing popularity of the town as a winter resort. The Duc de Chambord, who died at Görz in 1883, was buried in the Franciscan monastery outside the town, where also lie the remains of King Charles X. of France. Population (1890), 21,825; (1900), 25,432; two-thirds Italians, the rest mostly Slovenes and Germans. There is a garrison of 1761 men. The population is almost entirely Catholic, the Jews, Protestants, and members of the Greek Orthodox Church forming a mere fraction.

Goschen, George Joachim Goschen, 1ST VISCOUNT (1831——), British statesman, son of William Henry Goschen, a London merchant of German extraction, was born in London, 10th August 1831. He was educated at Rugby under Dr Tait, and at Oriel College, Oxford, where he took a first-class in classics. He entered his father's firm of Fruhling & Göschen, of Austin Friars, in 1853, and three years later became a director of the Bank of England. His entry into public life took place in 1863, when he was returned without opposition as member for the City of London in the Liberal interest, and this was followed by his re-election, at the head of the poll, in the General Election of 1865. In November of the same year he was appointed Vice-President of the Board of Trade and Paymaster-General, and in January 1866 he was made Chancellor of the Duchy of Lancaster, with a seat in the Cabinet. When Mr Gladstone became Prime Minister in December 1868, Mr Goschen joined the Cabinet as President of the Poor Law Board, and continued to hold that office until March 1871, when he succeeded Mr Childers as First Lord of the Admiralty. In 1874 he was elected Lord Rector of the University of Aberdeen. Being sent to Cairo in 1876 as delegate for the British holders of Egyptian bonds, in order to arrange for the conversion of the debt, he succeeded in effecting an agreement with the Khedive. In 1878 his views upon the County Franchise question prevented him from voting uniformly with his party, and he informed his constituents in the City that he would not stand again at the forthcoming General Election. In the following August he attended the International Monetary Conference at Paris. In 1880 he was elected for Ripon, and continued to represent that constituency until the General Election of 1885, when he was returned for the Eastern Division of Edinburgh. Being opposed to the extension of the franchise, he was unable to join Mr Gladstone's Government in 1880; declining the post of Viceroy of India, he accepted that of Special Ambassador to the Porte, and was successful in settling the Montenegrin and Greek frontier questions in 1880 and 1881. He was made an Ecclesiastical Commissioner in 1882, and when Sir Henry Brand was raised to the peerage in 1884, the Speakership of the House of Commons was offered to him, but declined. During the Parliament of 1880–85 he frequently found himself unable to concur with his party, especially as regards the extension of the franchise and questions of foreign policy; and when Mr Gladstone adopted the policy of Home Rule for Ireland, Mr Goschen followed Lord Hartington and became one of the most active of the Liberal Unionists. His vigorous and eloquent opposition to Mr Gladstone's Home Rule Bill of 1886 brought him into greater public prominence than ever, but he failed to retain his seat for Edinburgh at the election in July of that year. On the resignation of Lord Randolph Churchill in December 1886, Mr Goschen, though a Liberal Unionist, accepted Lord Salisbury's invitation to join his Ministry, and became Chancellor of the Exchequer. Being defeated by Mr Nevill, a Gladstonian Liberal, at Liverpool, 26th January 1887, by seven votes, he was elected for St George's, Hanover Square, on 9th February. His Chancellorship of the Exchequer during the Ministry of 1886 to 1892 was rendered memorable by his successful conversion of the National Debt in July 1889 (see NATIONAL DEBT CONVERSION). With that financial operation, under which the new $2\frac{3}{4}$ per cent. Consols became known as "Goschens," his name will long be connected. Aberdeen University again conferred upon him the honour of the Lord Rectorship in 1888, and he received a similar honour from the University of Edinburgh in 1890. In the Unionist opposition of 1893 to 1895 Mr Goschen again took a vigorous part, his speeches both in and out of the House of Commons being remarkable for their eloquence and debating power. From 1895 to 1900 Mr Goschen was First Lord of the Admiralty, and in that office he earned the highest reputation for his businesslike grasp of detail and his statesmanlike outlook on the naval policy of the country. He retired in 1900, and was raised to the peerage by the title of Viscount Goschen of Hawkhurst, Kent, on 17th December. He married in 1857 Lucy, daughter of Mr John Dalley, but lost his wife in 1898. In educational subjects he had always taken the greatest interest, his best known, but by no means his only, contribution to popular culture being his participation in the University Extension Movement; and his first efforts in Parliament were devoted to advocating the abolition of religious tests, and the admission of Dissenters to the universities. His published works indicate how ably he combined the wise study of economics with a practical instinct for businesslike progress, without neglecting the more ideal aspects of human life. In addition to his well-known work on *The Theory of the Foreign Exchanges*, he is the author of several financial and political pamphlets and numerous addresses on educational and social subjects. Among the latter may be mentioned that on *Cultivation of the Imagination*, Liverpool, 1877, and that on *Intellectual Interest*, Aberdeen, 1888.

Goshen, capital of Elkhart county, Indiana, U.S.A., on the Elkhart river, and on the Cleveland, Cincinnati, Chicago, and St Louis, and the Lake Shore and Michigan Southern railways, at an altitude of 800 feet. It has some manufactures, especially of waggons, agricultural implements, flour, &c., and a large lumber trade. Population (1880), 4123; (1890), 6033; (1900), 7810, of whom 462 were foreign-born.

Goslar, a town of Prussia, province of Hanover, situated at the north foot of the Harz, 31 miles by rail south by west from Brunswick. The post office (1893), classical school (1888), museum of the Natural Science Society (especially the collection of Harz minerals), the Fenkner Museum of Antiquities, and the miners' church of St Peter and St Paul (Frankenberg), built originally in 1108, rebuilt in 1225, and restored in 1880, deserve to be mentioned. The emperor's house was restored in 1867–80. Population (1885), 11,736; (1900), 16,403.

Gospels.—In this article a somewhat different order will be followed from that adopted in *Ency. Brit.*, vol. x. Points connected with the external evidence will be treated first for all the Gospels together, and we shall then pass to the evidence supplied by the study of the works themselves and their relations to one another.

I. *External Evidence.*

A few statements and conclusions in the earlier article seem to require revision in the light of later investigations.

(1) The three Epistles of Ignatius, as known through the Curetonian Syriac, are there regarded as genuine, while the seven Epistles in the short Greek or Vossian form are supposed to be an unauthentic expansion, and are assigned to A.D. 150. It has now been established, mainly through the labours of Zahn and Lightfoot, that the latter are genuine, and that their date must be thrown back somewhat. They may be placed between A.D. 110 and 130. This difference of twenty to forty years is not unimportant in relation to the stages in the recognition of the Gospels.

(2) Formerly the view was taken that the first three Gospels were the documents designated by Justin as *Apostolic Memoirs*, and his chief authorities; but that he made no use at all, or at most an extremely slight one, of the Fourth Gospel, and that his only source besides for the Gospel history was oral tradition. The progress of inquiry has confirmed the opinion that Justin did use the Synoptic Gospels, or at all events, Matthew and Luke, and that they were among the works chiefly referred to by him under the name *Memoirs of the Apostles*. It has, besides, been decidedly favourable to the belief that he knew and used the Fourth Gospel also.

Did Justin Martyr use the Fourth Gospel?

The majority of critics, including many who cannot be suspected of conservative bias, now hold this. A. Hilgenfeld, who in 1850 declared it to be "in the highest degree improbable that he was acquainted with it" (*Krit. Untersuch. über die Evang.*, p. 304), writes in 1875 that "the use [by Justin] of the Johannine Gospel would be difficult to deny" (*Einleit.*, pp. 66, 67); compare Keim, *Jesus of Nazara*, i. p. 186 ff., English translation; Thoma, *Genesis des Evang. Johann.*, p. 824; H. Holtzmann, *Einleit.*, 3rd ed., p. 100; Jülicher, *Einleit.*, p. 293; Harnack, *Chronol.*, i. p. 673 f. At the same time, these writers do not admit that Justin attributed Apostolic authority to the Fourth Gospel, though they allow that he did to the others. This is a point to which we shall return. Among writers who are more unreserved in their admissions as to the testimony borne by Justin's writings to the Fourth Gospel, Prof. James Drummond, *Theological Review* for October 1875, and April and July 1877, and Dr Ezra Abbot, *The Authorship of the Fourth Gospel, External Evidences*, pp. 16–48, may be specially mentioned.

In judging of the signs of Justin's use of the Fourth Gospel, care must be taken not to exaggerate the contrast afforded by his use of Matthew. This is the Gospel from which he unquestionably takes most, but he does not "quote" it in the strict sense of the word. He nowhere refers to it specifically; with only one or two exceptions he does not give its words exactly; most often he departs from it considerably, condensing, or combining passages from different parts of it, and from parallels in Luke. To say the least, we cannot expect greater exactness when he reproduces the substance of passages of the Fourth Gospel.

Further, the verdict must depend upon the cumulative force of a number of indications, many of them slight in themselves. The evidence cannot be massed and examined here, but a few illustrations may be given. In *Dial.* c. 69, in one of his customary summaries of facts which were fulfilments of prophecy, there are no fewer than three traits which forcibly remind us of John. One of these relates to a charge brought by the Jews against Jesus. There are many other allusions in different places in the *Dial.* to our Lord's conflicts with the Jews, which recall this Gospel specially (*e.g.*, comp. turns of expression in *Dial.* c. 136 with Jn. v. 37, 38, 23, 24). To pass to theological teaching: the correspondence between Justin and the Fourth Gospel in regard to the doctrine of the Person and Mission of Christ is extensive. See, *e.g.*, for several points, *Apol.* ii. 6, comparing Jn. i. 1, 2, 3, 12, 13. The peculiarly Johannine thoughts, that Christ came from the Father, that the Father sent Him, that He fulfilled the Father's will, that He derived His power from the Father, are prominent in Justin. See, *e.g.*, *Apol.* i. 6 and *Dial.* 64, and comp. Jn. i. 9, iii. 31, xii. 46, &c.; *Apol.* 14, and comp. Jn. xiv. 6; *Dial.* 140, and comp. Jn. iv. 34, xiv. 10, &c.; *Dial.* 30, and comp. Jn. v. 36; *Dial.* 100, and comp. Jn. x. 18. The same types also appear. In addition to "the light" and "the living water," which will be found in passages already referred to, we have the brazen serpent twice (*Apol.* 60, and *Dial.* 91; see especially the latter).

Among the largely increased number of students who have been convinced that Justin was acquainted with the Fourth Gospel, there are, at the same time, as we have observed, those who hold that it did not in his estimation take rank, like the Synoptics, as a member of the class of *Memoirs of the Apostles*. The ground for supposing this difference is chiefly his more limited and less distinct use of it. But as regards this, it may well be urged that the contents of the Fourth Gospel were on the whole less suited to the purpose he had in hand. It may be added that there are passages in which, according to the most natural interpretation of his language, statements taken from the Fourth Gospel are referred to the Memoirs. (See *Dial.* 105; also *Apol.* i. 46, where he says that "we were taught"—no doubt he would say on the authority of the Apostles, and probably by means of their "Memoirs"—that "Christ was the Word of Whom the whole race of men partook." Comp. also *ibid.* c. 66.)

A few words must be added on another point in connexion with Justin, viz., the question whence he derived those traits and incidents in his representation of the Gospel history, which cannot be traced to the Gospels, or to reflexion upon Old Testament prophecies, aided by his own imagination. Here the view adopted in the earlier article is that which "orthodox" writers had commonly maintained. The use by Justin, to an appreciable extent, of any written source or sources other than the Gospels is denied. Few critics of any school would now feel able to agree to this. Seeing that Hegesippus, a contemporary of Justin, is said by Eusebius to have quoted from the Gospel according to the Hebrews (*H. E.* iv. 22), and that another contemporary, the author of the Homily commonly called the 2nd Ep. of Clement, also quotes from an Apocryphal Gospel, apparently that according to the Egyptians, it is in itself probable that Justin may have known some such work or works, and been quite ready to give credence to its or their statements. Some parallels may be noticed between Justin and the recently recovered fragment of the *Gospel of Peter*, and several critics think that Justin himself refers to this work when he says that a fact about Peter and certain other Apostles is recorded in his (Peter's) Memoirs (*Dial.* 106)—hereby assuming that if we had the whole work we should find therein the statement in question. But there is a passage entirely to the purpose in Mark iii. 16, 17, and Justin's words can be satisfactorily explained as an allusion to this Gospel. It should also be observed that in those few particulars in which there is a measure of resemblance between Justin and the Gospel of Peter, the former (to speak generally) is nearer to the Gospels. In one important respect his language is directly opposed to that of the work in question.

If Justin was not only acquainted with the Gospel of Peter, but believed it to be the composition of that Apostle, or to embody his testimony, he must have regarded it as a high authority. It is contrary to the evidence to suppose that he did this. Whether he included any other writings, afterwards reckoned by the Church as "apocryphal" among his *Apostolic Memoirs*, or even while admitting them to this class was conscious of any difference in value and authenticity between them and other members of it to which afterwards a unique position was attributed, are questions which the indications in his writings hardly enable us to decide.

Earliest evidence of grouping of Gospels.

(3) The so-called Muratorian fragment on the Canon would not now generally be placed so early as A.D. 170. Lightfoot in his latest work seems to regard A.D. 185–190 as more probable (*Apostolic Fathers*, Part i. vol. ii. pp. 413 and 495). Zahn arrives at about A.D. 210 as its date (*Kanon*, ii. 136). The first formal list of the writings of the New Testament which we know of must thus be held to belong to a somewhat later time than has often been supposed.

But as regards the evidence of the special recognition of the four Gospels there is an equivalent in the fuller knowledge which has been obtained of Tatian's *Diatessaron*. Little room now remains for doubting that this work was an account of the life of Christ compiled from the Gospels—from these and not in any comparable degree from other sources, and also not more from the Synoptics than from the Fourth Gospel, with the first words of the Prologue to which the work began, "In the beginning was the Word."[1] The importance of this fact will be perceived, if we bear in mind that Tatian was at Rome with Justin Martyr, and speaks of him with profound reverence. We may take A.D. 160–180 as the period of his chief literary activity.

Authenticity generally.

(4) In judging of the external evidence as to the authenticity of the Gospels, and in an especial manner of the Fourth Gospel, it is essential that we should take account of the position held by the four Gospels in the Church at the end of the second and beginning of the third century, and should endeavour to estimate the age and strength, and to speak generally the trustworthiness, of the traditional beliefs on which it rested. This is a subject on which some of the chief writers on the Canon in recent times have joined issue. It is admitted on all hands that at this epoch the four Gospels were regarded in the most prominent Churches of the Roman Empire as the embodiment, in an altogether unique sense, of the Apostolic testimony in regard to the life and teaching of Christ. Irenæus (*Adv. Hær.* book iii. cc. 1–11) is a witness for ancient Churches on the western coast of Asia Minor and Rome, as well as Southern Gaul; the Muratorian fragment is another witness as to the Church of Rome, whether it is, or is not, by Hippolytus, as also are the undoubted works of Hippolytus; Clement of Alexandria (*Strom.* iii. c. 13) for that great Christian community. Tertullian (*Adv. Marcionem*, iv. 5), again for Rome as well as for North Africa. It can hardly be doubted that the authority of the fourfold Gospel was equally firmly established in at least some other Churches which are not so directly represented; while soon after this time it had certainly come to be accepted in all parts of the Church. Books which had only lately become known could not have been regarded as these were in those divers Churches, and by those eminent teachers to whom we have referred. These men themselves had a long and wide experience of Christian tradition. Irenæus refers in particular to his recollection of what as a boy he had heard Polycarp relate concerning John, by whom he evidently means the Apostle. It has been said that as Irenæus appears to be mistaken when he asserts that Papias was a hearer of John, confusing here between John the Apostle and a certain elder John, so he may be mistaken in the case of Polycarp. His statement, however, in regard to Papias seems to have been founded on what he had read in the latter's book; and it is one thing that he should have formed and preserved an erroneous impression thus, quite another that he should be at fault in reminiscences of what he had heard in early youth, about the distinctness of which in his own case he is very emphatic. But it is, perhaps, more important to observe that in regard to the tradition of the residence of St John in Ephesus, and all that concerned the recognition of the Fourth Gospel, as well as the other three, there must have been abundant opportunities for his own memory to be corrected by that of many other Christians both of the same age as, and older than, himself. The place which we find the four Gospels occupying at the epoch we have indicated was due to an appreciation of their value which had grown by degrees; yet at the same time it would seem to have been one which could not have been attained without a long-standing conviction as to their peculiar claim to be trusted. When written accounts of the life of Christ were put forth—which, according both to the view traditional in the Church and other evidence, was not till about or after the close of the lives of St Paul and St Peter—they naturally did not cause the oral method of transmitting the facts, hitherto relied on exclusively, to be at once laid aside. But as those who could themselves remember the Apostles and their fellow-labourers and the teaching given by them passed away, the importance of documents which came down from the Apostolic age, or its confines, necessarily increased. There are inequalities for a certain period in the signs of their distribution and use. But this is easily understood when it is considered that they appeared in different quarters, and that an interval of about thirty years (again according to both tradition and criticism) elapsed between the publication of the earliest and the Fourth; and when in addition we remember the labour of copying, and allow for the probability that one rather than another might in a special manner commend itself to various individual minds and Churches. Again, attention was at first fixed upon the substance of the Gospel; the precise words of the record were comparatively little regarded. Hence there was small reason for indicating particular sources; and when two or more sources contained parallel passages, there was a disposition to combine them instead of quoting them in their distinctness. Of these statements abundant proofs might be adduced from the writings of the sub-Apostolic age and the Apologists of the middle of the 2nd century. With time the distinct value of each of the several records was perceived, and a conception of their relations to one another was attained. Here, as in many other cases, the work of definition was promoted by conflict with heresy. Gnostics, and others who held more or less exaggerated and one-sided views, were wont to exalt one or more of the four Gospels to the disadvantage of the remainder, or to make use of other Gospels.[2] Hence arose the need of marking off clearly those which were to be deemed authentic, and of insisting that all these were alike to be reverenced. The intrinsic worth of the four Gospels, their manifest superiority to all other works of the kind, and their agreement with the tradition of Apostolic doctrine, may have had a share in procuring this result. But the conclusion in question seems to have been formulated even more on the ground of the actual history of the Gospels. Indeed, we may say with confidence that it could not without this external reason have been arrived at so swiftly and surely, with so little doubt and debate, as it was, when we consider the unfitness of the masses of men at all times, and peculiarly so of the early Christians, for forming a decision on critical grounds. In this connexion it is well to note that, according to the information which we possess, the leading part in framing this Canon of the Gospels was taken by the chief Churches in that Greek-speaking world for which the Gospels (not excepting the First in the form in which we have it) were composed.

II.—*Internal Evidence.*

1. *The Synoptic Problem.*—The "originality of Mark" is a thesis maintained at the beginning of the article in the ninth edition of this work. It is there argued that the

[1] For a narrative of the literary finds and investigations which lead to this conclusion, see *The Diatessaron of Tatian*, by S. Hemphill; or the introduction to *The Diatessaron of Tatian*, by J. H. Hill.

[2] See Iren. *Adv. Hær.* iii. xi. 6; and for the attitude of the Alogi to the Fourth Gospel, *ib.* § 9, and *Epiphan. Hær.* li.; also, for use of Gospel of Peter by Docetae, Eus. *H. E.* vi. 12.

Second Gospel cannot be derived from the First and Third, and that on the contrary it most nearly represents, for that portion of the Gospel history which it gives, a source used in the First and Third. These are some of the most widely accepted and most secure results of modern criticism as to the literary relations of the Gospels. It will not be necessary here to dwell further upon them.

Was the common source oral or written?

We go on to ask whether the common source was oral or written. In judging of this question we must take account not only of the amount of agreement between all three Synoptics, but also of the still fuller agreement between Mark and the two others separately in the same contexts. When, for example, in a passage, the substance and many of the words and phrases of which are common to all three, we find whole sentences and the general structure of the passage identical in Matthew and Mark, though Luke differs more or less, the obvious inference is that the fixity of the common source must at least be measured by the resemblance between the two first, and that the third has departed from it. But this is the case again and again. In like manner there are numerous instances, though, on the whole, not so many, in which Mark and Luke agree, where Matthew is independent. Nearly the whole of the subject-matter, and to a large extent the phraseology, of Mark reappear in Matthew and Luke taken together. Further, the correspondence between the Synoptics, not only in regard to language and the form of separate narratives, but also in regard to the sequence of sections, needs to be particularly noted. And the agreement between the pairs Mark and Matthew, Mark and Luke, once more calls for explanation, as well as that between all three. In point of fact, Mark's order is almost invariably supported by one of the others, as well as frequently by both. The amount of agreement of these different kinds is so great that to the majority of students of the subject at the present time it seems impossible to explain it solely by the influence of a common oral tradition, even when every allowance is made for unusual conditions which may have tended to give stability to such a tradition.

The common source, then, was a document in which almost the whole of the contents of Mark was found, given at least nearly in the same form and arranged in the same manner. Whatever else we may be able to learn about this document, *e.g.*, as to whether any other matter was included in it, we have thus made a first approximation to a knowledge of its character.

We have traced agreements between Mark and either of the other two Synoptics to a source which was also known to and largely used by the third.

Matter common to SS. Matthew and Luke.

May we not, then, also see the same common source revealed in the agreement of the other pair, Matthew and Luke? The answer is that it would not be unreasonable to do so on the same condition as before, viz., that the agreement occurs as part of a more general parallelism between all three. But while this holds universally in connexion with the coincidences between Mark and one of the others, those of Matthew and Luke where this requirement is satisfied are comparatively rare, and they consist for the most part only of isolated words or brief phrases.

An instance in which the agreement is more extensive is afforded by a comparison of the passages in the three Synoptics on the preaching of the Baptist. The relations between the three may be satisfactorily explained by the supposition that the matter which is verbally identical in Matthew and Luke, but omitted by Mark (Matt. iii. 7–10 and 12; Lu. iii. 7–9 and 17), together with the words given by all three (Matt. iii. 11; Mk. i. 7, 8; Lu. iii. 16), was taken from the source from which the common elements generally in the three Gospels are derived. There may be one or two other pieces of discourse in regard to which the same view may deserve to be considered. Holtzmann, however, refers a good deal more matter which is not given in Mark to the same source, where there is not the reason which I have indicated, or any other sufficient grounds for doing so (see below).

The greater part of the matter not contained in Mark, which is common to Matthew and Luke, falls into another category. It is introduced into the Synoptic outline very differently in these two Gospels. This fact clearly suggests that it existed in a separate form, and was independently combined by the first and third Evangelists with the contents of that source which we have hitherto had before us. This matter has also a character of its own; it consists mainly of pieces of discourse; and it is not difficult to imagine influences which during the period of oral teaching may have tended to secure the collection of considerable portions of it at least, in the shape in which we have it. (Comp. Weizsäcker, *Apost. Age*, ii. p. 32 ff., in Eng. trans.) It is, perhaps, most generally believed by critics at the present time that the first and third Evangelists derived it from the same document. But the grounds for supposing a common written source are not so strong in this as in the former case. Some connexion between the source or sources used in the two Gospels must, no doubt, be assumed, for parts of it are reproduced in the two in exactly, or almost exactly, the same form. But in other parts, as pointed out in the earlier article, the agreement is far less close. This strange variety requires explanation. Further, the arrangement of the whole of this matter in Matthew and Luke is very different, not only, as we have already noted, with reference to the general plan of the Gospel narrative, but also regarded simply by itself. It is far more broken up in Luke. If, then, its derivation from a single common document in both is assumed, we have to ask in which of the two that document has been most faithfully followed; or, in other words, whether the first Evangelist has brought together what he found dissevered, or the third has scattered what he found united. The former of these processes would seem to have been the easier and the more natural. But this view of the origin of the difference is hard to reconcile with the tradition which, on the strictest grounds of historical criticism, ought to have considerable weight, as to the connexion of Matthew with the First Gospel. It would still be possible, indeed, that the common document might have been his work, but the Third Gospel would, at least in important respects, be the truest representative of it.

This objection may be avoided, and we shall have a theory which, it would seem, takes account more fully of all the facts, if we suppose that the particular collection of the matter we are considering, which has been embodied in Matthew, was not directly used by the third Evangelist, but that he himself compiled the similar matter which he gives from what he had learnt by oral transmission or obtained in the form of written fragments. Those passages in which the two Gospels agree almost verbally may have been first copied from a Greek version of the Matthew document by some who were making smaller collections of the teaching of our Lord on particular topics for their own use; or, again, they may have been pieces early translated from the Hebrew document, or even portions of Greek oral tradition that had been written down, which were introduced by the editor of the Greek Matthew at the places to which, according to his original, they belonged, but which, as we have supposed before, came independently into the hands of the third Evangelist. The latter seems expressly to claim that the arrangement of what he related was his own (Lu. i. 3).

It will be desirable now to say a few words on the composition of each of the three Synoptic Gospels individually, taking into account as we do so what we have learnt from comparing them, and also touching upon any other points which need to be considered.

St Mark.

Can we determine somewhat more exactly than we have hitherto done how the Second Gospel was related to the document which was at least most nearly reproduced in it? (*a*) To what extent did it differ therefrom by abbreviation? We have seen that the additions to this source which can with any high degree of probability be made on the ground of parallelisms in Matthew and Luke are but scanty. Holtzmann, however, supposes that it contained among other things the Sermon on the Mount. The omission of this sermon, and (with the exception of a couple of sayings) of all parallels to its contents, is a remarkable feature of the Second Gospel. It is impossible to imagine that its author, or editor, could have been ignorant of the whole of this matter. That he should have passed it over entirely, if it was included in his own principal document, would also have been very strange. That he might have thought its inclusion by himself unnecessary would be somewhat more easy to understand, if it had already been set forth in another writing. (*b*) Scattered throughout Mark there are forcible and vivid touches which do not appear in the parallels in Matthew and Luke. Were these added to the document which lay before them subsequently to their use of it? There hardly seems to be good reason for thinking so. Many of the expressions in question appear to be in the style which, to all appearance, belonged to the original document. The third Evangelist often revised, recast, and condensed that which he took from it. To a more limited degree the first did the same. It is natural that their omissions should in some instances have coincided. That some changes were made in the original work during the earliest period of its circulation is not improbable. But these appear to have been slight. On the whole we are justified in believing that the Second Gospel is substantially the work which, as Papias learned from "the Elder," Mark composed from his reminiscences of Peter's teaching.

St Matthew.

The editor who has given us the First Gospel in its present shape in Greek employed mainly, if not exclusively, two documents. Discourses and sayings were the most characteristic contents of one of these, though it is possible that some narratives may also have been comprised in it. Occasions on which the teaching recorded was given may probably have been indicated in it to some extent; but words spoken at different times which bore on the same subject would seem not infrequently to have been put together. This work was originally written in Hebrew (or Aramaic), and if not by the Apostle Matthew, was at least known to represent what he had taught. The editor of the Greek Matthew either himself translated this work, or so much of it as he required for his purpose, or had before him a translation which had already been made. But along with this he used Mark's narrative. Nay, he may without serious exaggeration be said to have incorporated the Matthew document with it. It supplied the framework, while in passage after passage we have virtually a transcript from it, with here and there an abbreviation or the omission of a sentence that may well have appeared redundant, or with some other saying woven in. Additional sayings in such contexts need not indicate the existence of an account parallel in other respects which contained them. They may have been introduced from some distinct group of sayings in the other document, or be fragments of oral tradition inserted by the editor of the Greek Gospel. Yet it is in itself probable that the two documents overlapped; and where sections which have parallels in Mark are not placed in the same connexion as these, or have many marks of an independent origin in their form and substance, or differ in both respects, it is reasonable to see in these variations the influence of the Hebrew original.

It is especially noteworthy that where the placing differs, the similarity in other ways is also less close than usual. Comp. Matt. viii. 23–34 with Mk. iv. 35–v. 20; Matt. ix. 18–26 with Mk. v. 21–43; Matt. x. with Mk. iii. 13–19*a*, and vi. 6*b*–13. (Matt. x. contains much matter which is given in various places in Luke, also six verses (17–22) closely parallel to Mk. xiii. 9–13.) Sometimes, however, Mark's outline seems to have suggested the point for introducing a passage which, though it has a parallel in Mark, seems to have been derived from another source. Thus Christ's answer to the charge of the Pharisees that He cast out devils by Beelzebub occurs in the same general connexion in Matthew as in Mark (Matt. xii. 24; Mk. iii. 22); but the incident which gave rise to the charge is the same as that in Luke (xi. 15–26), where it is part of his "great insertion," while the language of the answer has also far closer affinities with that in Luke than in Mark. Again, a discourse "concerning offences" is given in Matt. xviii. 5–35, in a position corresponding to the one in Mk. ix. 42–50, and several of the sentences in Mark are almost verbally reproduced; but with them we find combined both much that is peculiar and also a short piece on the same topic, which is placed by Luke (xvii. 1–4) towards the close of his "great insertion." Another narrative occurring in a context which closely resembles Mark, but containing itself many signs of independence, is that of the Canaanitish woman (Matt. xv. 21–28; Mk. vii. 24–30).

St Luke.

We possess no such specific information from any early writer in regard to the composition of St Luke's Gospel as we do in the case of Matthew and Mark. But when we examine it in conjunction with the Acts of the Apostles, which is evidently by the same author, we obtain strong confirmation of the traditional view of the authorship. (*a*) We may indicate first an argument based on literary style and vocabulary. As was remarked in the earlier article, there are variations of style in the Gospel, and so there are in the Acts. Nevertheless characteristic words and phrases, which for convenience we will at once call "Lucan," occur throughout, and evidently proceed from the author of the works in their final shape, though in parts where he is using materials derived from others, or possibly adopting a style suited to a special theme, they are naturally less frequent. Certain sections, however, of the Acts, commonly called the "we" sections from the use in them of the first person plural (xvi. 10–17; xx. 5–15; xxi. 1–18; xxvii. 1–xxviii. 16), are generally admitted to be notes of travel by a companion of St Paul. Now it is a remarkable fact that "Lucan" words and phrases are specially abundant in these sections. The inference is that the writer of them was the author of the book as a whole and of the Gospel. (*b*) There are the geographical accuracy and the other elements of historical credibility which have so much impressed Professor W. M. Ramsay and others.

Luke, as well as the editor of the Greek Matthew, used Mark; but he revised its language much more freely, and omitted more. He also supplemented it with other material, but this—if arguments which have been briefly urged above are sound—was not taken from a single source, but amassed by himself through personal inquiry and labour.

2. *The Fourth Gospel.*—The special characteristics of the Fourth Gospel have been for the most part sufficiently brought out in the article in *Ency. Brit.*, vol. x. There would be agreement as to many of them among students who have examined the Gospel from very diverse points of view. The additional remarks here made will mainly have reference to the bearing of those characteristics upon the question of the credibility of the narrative, and their

object will be to direct attention to some points which seem to have been too much disregarded in that article.

(*a*) The foregoing brief inquiry into the history of the composition of the Synoptic Gospels, while it justifies us in regarding them as inestimably precious for what they relate as to the Life and Teaching of Jesus, should prevent us from erecting them into a standard by which every other treatment of the same theme should be tried. There is good reason to think that the material which has been preserved in them had been authenticated by eye-witnesses; but no one of the authors of the works in their present form was in a position to furnish an approximately complete view of their common subject.

Differences from Synoptics.

In respect of one difference between the Synoptics and the Fourth Gospel, namely, the mention by the latter of several visits to Jerusalem at the time of Jewish Feasts, to which the former make no reference, probability is overwhelmingly strong on the side of the Fourth Gospel. In the Synoptic Gospels Jesus is represented as ready to conform to the requirements of the ancient Law. This being so, He could not have refrained persistently from going up to Jerusalem for the great Feasts. Even without this reason He must have been attracted there by those great gatherings of Jews which afforded such excellent opportunities for the fulfilment of His prophetic Mission. In addition to this, we cannot understand the final catastrophe, apart from such previous conflicts between Jesus and the ruling classes in Jerusalem as are described in the Fourth Gospel. His work in Galilee did not sufficiently threaten their authority to have given birth to a settled determination to destroy Him. Nor could their design and plot against Him have taken shape within three or four days after His triumphal entry.[1]

To turn to the Teaching of Jesus: the thoughts in the Fourth Gospel are less apparently simple, and are less confined within Jewish forms. But ought it to be supposed on that account that they are less likely to have been those of the Master Himself? Is the matter-of-fact writer always able to give a truer estimate of a great character, or of a mighty and complex movement, than the man of reflective mind and philosophical bent? That the latter's representation is more liable to be coloured by his own individuality is of course to be admitted. But in spite of this the advantage is not wholly, or even chiefly, on the side of the man of more limited mind and nature. There might well be portions of the teaching of Jesus which the whole body of the Twelve at first, and many of them to the end, understood very imperfectly, which would be little reflected in the ordinary instruction given to Jewish and other converts in Palestine or elsewhere, and the significance of which could only be apprehended by a man of peculiar depth and intensity of mind after long meditation, and when experience had thrown light upon them.

(*b*) The author of the Fourth Gospel undoubtedly desires not merely to give a faithful record of the deeds and words of Jesus, but to impress upon his readers his own view of the Person and Mission of Jesus; and with this intention he makes a selection among the facts, relating, or giving special prominence to, those which are suitable for his purpose. Such selection, designed to bring out certain aspects of the truth, may be perfectly legitimate and necessary. But we have to ask whether the effect which the beliefs of the Evangelist have had upon his narrative extends farther than this. Has his conception of the Person of Jesus led him to transform the facts so that he is not a trustworthy witness even in what he states?

In this connexion we will consider, first, the question of the influence upon him of Philo's philosophy. That there are points of contact between the thought and language of the Fourth Gospel and those of Philo is unquestionable. But was the Evangelist a disciple of Philo, who, after being well grounded in that philosophy, embraced the Gospel, and who, in his later faith, sought for an exemplification of the principles he had before held? Or was he simply a thoughtful Christian believer, who, having formed his idea of Christ and His Mission primarily from the utterances of Jesus Himself and all the facts concerning Him, was ready to avail himself of terms and forms of thought taken from Philo, when he met with them, in order to express what was already in his mind? In the former case there would be far greater danger that his impressions in regard to the facts and his presentment of them might be affected by philosophy than in the other, and consequently, in judging of his trustworthiness as a historian, it should make a wide difference whether his relation to Philo was of the one or the other kind. A careful comparison between the Fourth Gospel and the writings of Philo brings out the essential independence of the Evangelist. Philo's language on the being of the Logos and the relations of the Logos to God and to the world is wavering and contradictory. It is exceedingly difficult to obtain a clear idea of his system of thought, and very different judgments have been formed upon it. The Evangelist, on the other hand, shows a thorough mastery of his subject. In the few verses of his Prologue he gives in firm, strong outlines a majestic view of God and of the whole scheme of creation and human history. He is able to do this because his mind is under the power of certain dominant thoughts, which he did not derive from Philo. The relation of the Father to the Son, and of the Son to the Father, manifested through the Incarnation, have, for him, illuminated the doctrine of the Logos. Nor, on the other hand, are there any signs that the lines of philosophical speculation which commended the great concept of the Logos to Philo were of special interest or significance for the Evangelist. Again, there is evidence of a sense, to say the least, of historic propriety in the fact often noticed, that the use of the term "the Word" to describe the Person of Christ is confined to the Prologue. An instance of a similar kind is the restricted use of μονογένης, an epithet applied to the Logos in Philo. It occurs only in the Prologue (i. 14, 18), and in the comment of the Evangelist (iii. 16–21), which is virtually a prolongation of the last note of the Prologue.

The influence of Philo.

The places after the Prologue in which we have the nearest parallels to the language and thought of Philo are the passages in which Jesus speaks of Himself as the Manna (vi. 26 ff.) and the Light of the World (viii. 12; ix. 5). But it should be remembered that there were other associations which might well have suggested the use of these figures; and further, it should be observed that the whole mode in which they are applied accords with the conditions of His Incarnate state. He is the food of man by that which He communicates through His flesh (vi. 51 ff.). He is the Light to those who mark and follow His human example (viii. 12). The absence, too, of one trait is specially noteworthy. Philo dwells on the high-priestly character of the Logos, whereas the priesthood of Christ is not named or indicated in the Fourth Gospel.[2] And yet that it should have been would have been rendered

[1] In the ninth edition (see vol. x. p. 832, *n.* 3) it is allowed only that the Fourth Gospel may possibly be right as to there having been visits to Jerusalem before the last Passover season, and the really strong reasons for believing that there must have been are overlooked. In the case of another difference between the Fourth Gospel and the other three, that in regard to the day of the Crucifixion, it is more decidedly admitted (*ib.* 828) that the Fourth has the advantage.

[2] Unguarded expressions in *Ency. Brit.*, vol. x. (pp. 824, 827, 830, *n.* 2) may be taken to imply the contrary.

natural even by considerations such as appear in the Epistle to the Hebrews. The fact is also the more striking, because the thought of Christ's death as a propitiation, which is utterly alien to Philo's philosophy, is strongly emphasized. That is, He is set forth as a Sacrificial Victim, but not as the Priest.

Universalism. It is evident that the author of the Fourth Gospel had a conception of the Mission of Christ which transcended all limits of nationality, and that it is part of his aim to bring out its universal and eternal significance. Yet in connexion with this, again, we have marks of fidelity to the actual history. We gather from this Gospel no less than from the Synoptics that the Ministry of Jesus was exercised primarily, and almost exclusively, towards Jews. There is an exception—His conversation with the Samaritan woman, and preaching in a Samaritan village—just as there are one or two exceptions also in the other Gospels. It is true the exception is dwelt upon at considerable length, and the occurrence is the occasion for some profound instruction. But it should also be observed that remarks are introduced by the Evangelist which seem expressly designed to show that this labour formed no part of the proper plan of Jesus (iv. 3, 39, 40).

The portraiture of Jesus. It is said that the human nature of Christ is disregarded in the Fourth Gospel. This plainly is not true in respect to physical infirmity (iv. 6) or human emotion (xi. 35, 38). But it is more important to note that we must turn to this Gospel for the fullest and most vivid representation of Jesus as the perfect Son of the Heavenly Father under the conditions of humanity, living here below a life of dependence upon and submission to the Father, doing on earth the Father's Will, not less than for the plainest declaration of the doctrine of His Divine, Eternal Sonship. In reviewing its teaching as a whole, we may be led to feel that His absolute, Divine Sonship is presupposed even in those passages in which it is not directly suggested. In point of fact He could be *perfect* even as the human Son only in virtue of His true Divinity. Nevertheless, it is an important point that in many places in this Gospel Jesus speaks so completely from the standpoint of humanity, that the question of His Divinity is not raised, or not necessarily so (*e.g.*, iv. 34; vii. 16–18; xiii. 16, 20; xv. 21).

Particularity of description. (c) Some names used, and classes referred to, in the Synoptics do not occur in the Fourth Gospel. We do not hear in it of "scribes" and "elders," terms which would be very misleading to Greek readers; in place thereof we have the easily comprehensible word "rulers." The Sadducees —mentioned only once in Mark and Luke, where Christ gives His answer regarding the Resurrection, and the introduction of whose name in Matthew in two other connexions does not further illustrate their doctrines or party-relations—do not appear; nor do the Herodians, named twice in Mark (and in the parallel to one of these places in Matthew). But the character and position of the Pharisees are given far more clearly than in the Synoptics. Their influence is referred to (xii. 42), and their feeling of abhorrence for the people and its ground (vii. 49), both which traits are confirmed by what we know from Jewish sources. The various parts taken by those who brought about Christ's death stand out more distinctly and in a very life-like manner. The Pharisees watch His proceedings and the growth of His influence, carry on the doctrinal controversy with Him, and are the active instigators of measures against Him (vii. 32; viii. 13; ix. 13, 15, 40, 41; xi. 46, 47; xii. 19). The chief priests come upon the scene when it is a question of official action being taken and of treating with the Roman governor (vii. 32, 45; xi. 47 ff., 57; xii. 10; and cc. xviii., xix.). The special place assigned to Annas also agrees remarkably with other evidence respecting him (see Westcott's *Comm.*, note on Jn. xviii. 13). Christ's popularity with the people is noted (vii. 12; xii. 12, 19), and we are not left in any danger of thinking that the same "multitude" which followed Him with hosannahs clamoured shortly afterwards that Barabbas might be released in place of Him. Those who joined in this cry are "the Jews," a designation which includes Pharisees and Chaberim, men who were faithful members of the covenant, and others who desired to be associated with these (xviii. 12–15). The diverse motives which came into play with the conspirators, or were employed by them to induce Pilate to act, are also touched upon (xi. 48; xviii. 30, 31; xix. 7, 12, 15, 16).

The Evangelist's powers of analysis found an opportunity for even more characteristic exercise in marking the various degrees of faith in and loyalty to Christ among those who were attracted to Him. We are told of many who in His early ministry in Judæa believed, but whom He reckoned untrustworthy (ii. 23 ff.); of many disciples who turned back (vi. 66); of "Jews and Pharisees" after this who belonged in some sense to His following, and yet were ready to take offence at His words (viii. 31 ff.; ix. 40, 41); of men who were convinced, but who were unwilling openly to profess themselves His disciples because they had much to lose thereby (iii. 1 ff.; xii. 42; xix. 38, 39); as well as of the faithful few. And that there must have been this diversity we are sure from our knowledge of human nature and experience of Christian missions. And Jesus Himself depicted it in the Parable of the Sower, in which He doubtless describes what He saw beginning to take place around Him.

Authorship. (*d*) We have seen in discussing the external evidence in regard to the composition of the Gospels that the tradition which ascribes the authorship of the Fourth Gospel to John the son of Zebedee is one which cannot be lightly set aside; a close connexion of some kind between the work and that Apostle seems to be required to explain it. The statement in the book itself which bears most directly on the question—*this is the disciple which beareth witness of these things, and wrote these things* (Jn. xxi. 24)—has commonly been taken to mean that the disciple referred to was the author of the Gospel as a complete work—saving, perhaps, the immediately foregoing narrative. This is a possible meaning of the words, but hardly a necessary, or the most natural, one. They assert that the particulars were supplied by his oral testimony and by records he had left, but not that the arrangement of this matter and the setting in which it is placed are by him.

We turn to other considerations bearing on the question of authorship. The efforts to convict the writer of this Gospel of errors in regard to topography and Jewish customs have failed. The advantage must be pronounced to have lain very decidedly with the defenders of the Johannine authorship so far as the controversy in respect to it has turned upon signs in the work of acquaintance with the facts. The chief difficulties connected with the traditional view appear to be that the position of John the son of Zebedee and all the circumstances of his life for many years as one of the "Apostles of the Circumcision" (Gal. ii. 9) render it unlikely that he should have attained to the wide outlook of the writer of the Gospel; and that the Apocalypse, the authenticity of which as a work of the Apostle John is supported by strong external

evidence, is of the character which might be expected if it proceeded from one with those antecedents, while the differences between its style and thought and those of the Gospel are incompatible with identity of authorship, even when the longest interval that is at all possible has been assumed between the dates of their composition. It is not easy to gauge the amount of weight which should be allowed to these objections. The extent to which the views of the twelve Apostles were limited by Jewish prejudices must not be exaggerated. In particular, one who, like St John, never took the most leading part in the Church at Jerusalem, may well have held a larger faith than most of those with whom he associated, without being thereby brought into sharp conflict with them. Moreover, we ought not to set any narrow bounds to the development which might take place in one who, in those days of unexampled spiritual movement, surrendered himself to the Spirit's influence, especially when he found himself amid entirely new surroundings and brought face to face with new needs.

As regards differences between the Apocalypse and the Gospel, a few more years of residence at Ephesus would explain the greater command of Greek shown in the latter. It must also be borne in mind that for the same writer to attempt more than one form of composition, and in doing so to adopt a different style, is nothing strange. And the doctrinal contrasts may be more superficial than real. The visions of the Apocalypse may for the seer himself have been symbolical to a larger extent than we perhaps imagine; while, on the other hand, we may, through reading modern ideas into the language of the Gospel, be apt to fancy that the writer had discarded the ordinary conceptions of Christians of his time on such subjects as "the last things," far more than he actually had. Striking points of similarity between the Apocalypse and the Gospel have also been pointed out. (See Westcott, *Gospel of St John*, prolegomena, p. lxxxiv ff.)

These considerations, if they are not thought sufficient to remove all ground for calling in question the authorship of the Fourth Gospel by the son of Zebedee, serve at least to show that there need not have been any serious inconsistency between the spirit of his teaching and the thought of the Gospel, and that the actual author may well have been one who looked up to him as a master, and who sought to embody in the work what he had received from him. This view of the Apostle's relation to the Gospel, which we have seen is in harmony with the language of the book itself, appears to be that which does fullest justice to the various items of evidence, external and internal, and to all the probabilities of the case.

The Synoptic Problem.—The importance of mechanical helps by which the phenomena of relationship between the Gospels can be readily perceived alike broadly and in detail, was rightly insisted on in the earlier article. And the Synopticon by W. G. Rushbrooke, printed according to the plan there described (vol. x. p. 790), which was then in preparation, has since been published. Another much less expensive Synopsis, by A. Wright, has also appeared. In this work also the whole of Mark is first given continuously, with the corresponding portions of Matthew and Luke in parallel columns, then the passages parallel in Matthew and Luke only, &c. Various kinds of type are not made use of, as in the former work, except to a very limited degree, and so far it is inferior. But it possesses one distinct advantage in the arrangement of successive clauses in separate lines, whereby the remarkable similarities between the Synoptics in the structure of their sentences are clearly shown. No work of first-rate importance on the Synoptic problem has appeared recently either in England or in Germany. It is treated in a condensed form, but often with considerable thoroughness, in the various *Introductions to the New Testament*, of which several by writers of great learning and ability have appeared in Germany. It will be sufficient to mention those of H. Holtzmann, B. Weiss, and Th. Zahn. The second of these has been translated into English. The section also of Weizsäcker's *Apost. Zeitalter* on "the Evangelical Tradition" (bk. iv. ch. 2, in Eng. trans.) is valuable. In England there have been signs that interest in the subject has been revived and that it is being studied in various quarters, though as yet little has been published beyond popular accounts and articles in journals and dictionaries. One valuable contribution to the knowledge of the subject, published in a separate form, has however been made by Sir J. Hawkins in his *Horæ Synopticæ*. The "oral theory" still finds somewhat more favour in England than in Germany, and has been defended by the Rev. A. Wright, but it can no longer be said that the division of opinion on the point is "almost national."

St John.—Under the head of literature of the Johannine question, the section on "Die Johanneische Schriften" in Harnack's *Chron. d. Altchrist. Lit.* must be mentioned. It may be well also to name Delff's *Rabbi Jesu von Nazareth.* His position, especially in regard to the Fourth Gospel, is an eccentric one in some respects, but he draws attention to characteristics of this Gospel which ought to be pondered. The general reader will obtain a good idea of the controversy from the articles by E. Schürer and W. Sanday in the *Contemporary Review* for September and October 1891.

(V. H. S.)

Gosport, a seaport town in the Fareham parliamentary division of Hampshire, England, facing Portsmouth, across Portsmouth harbour, on the London and South-Western Railway. It is enclosed within a double line of fortifications, consisting of the old Gosport lines, and, about 3000 yards to the east, a series of forts connected by strong lines with occasional batteries, forming part of the defence works of Portsmouth harbour. Recent additions to the public buildings are a soldiers' home, a memorial hall, and a public library. Gosport is in the civil parish and urban district formerly called Alverstoke, but since 1891 Gosport and Alverstoke. Population (1881), 21,581; (1901), 28,879.

Goss, Sir John (1800–1880), English composer, was born at Fareham, Hampshire, on 27th December 1800. He was elected a child of the Chapel Royal in 1811, and in 1816, on the breaking of his voice, became a pupil of Attwood, through whom he may not impossibly have imbibed some of the Mozartian sweetness which characterizes his best work. A few early compositions, some for the theatre, exist, and some glees, &c., were published before 1825. He was appointed organist of St Luke's, Chelsea, in 1824, and in 1838 became organist of St Paul's in succession to his master, Attwood; he kept the post until 1872, in which year he officiated at the public thanksgiving for the recovery of the Prince of Wales, and subsequently, on his resignation, received the honour of knighthood. In 1876 he was given the degree of Mus.D. at Cambridge. Though his few orchestral works have very small importance, his Church music contains things that will not be forgotten, such as the anthems, "O taste and see," "O Saviour of the world," and others. Many anthems were published, as well as collections of chants, &c. He was the last of the great English school of Church composers who devoted themselves almost exclusively to Church music; and in the history of the glee his is an honoured name, if only on account of his finest work in that form, the five-part glee, Ossian's "Hymn to the Sun." He died at Brixton, London, 10th May 1880, and was buried at Kensal Green cemetery, and a tablet to his memory is in the crypt of St Paul's. (J. A. F.-M.)

Gosse, Philip Henry (1810–1888), English naturalist, was born at Worcester on 6th April 1810, his father being a miniature painter. In his youth the family removed to Poole, where Gosse's turn for natural history was noticed and encouraged by his aunt, Mrs Bell, the mother of the zoologist, Thomas Bell. He had, however, little opportunity for developing it until, in 1827, he found himself clerk in a whaler's office at Carbonnear, in Newfoundland, and beguiled the tedium of his life by continual observations, chiefly with the microscope. After

a brief and unsuccessful interlude of farming in Canada, during which he wrote an unpublished work on the entomology of Newfoundland, he travelled in the United States, was received and noticed by men of science, was employed as a teacher for some time in Alabama, and returned to England in 1839. His *Canadian Naturalist* (1840), written on the voyage home, was followed in 1843 by his *Introduction to Zoology*. His first widely popular book was *The Ocean* (1844). In 1844 Gosse, who had meanwhile been teaching in London, was sent by the British Museum to collect specimens of natural history in Jamaica. He spent two years on that island, and after his return published his *Birds of Jamaica* (1847) and his *Naturalist's Sojourn in Jamaica* (1851). He also wrote about this time several zoological works for the S.P.C.K., and laboured to such an extent as to impair his health. While recovering at Ilfracombe, he was attracted by the forms of marine life so abundant on that shore, and in 1853 published *A Naturalist's Rambles on the Devonshire Coast*, accompanied by a description of the marine aquarium invented by him, by means of which he had for the first time succeeded in preserving zoophytes and other marine animals of the humbler grades alive and in good condition away from the sea. This was more fully set forth and illustrated in his *Aquarium* (1854), succeeded in 1855–56 by *A Manual of Marine Zoology*, in two volumes, illustrated by nearly 700 wood engravings after the author's drawings. A volume on the marine fauna of Tenby succeeded in 1856. In June of the same year he was elected F.R.S. Gosse, who was a most careful observer, but who lacked the philosophical spirit, was now tempted to essay work of a more ambitious order, publishing in 1857 two books, *Life* and *Omphalos*, embodying his speculations on the appearance of life on the earth, which he considered to have been instantaneous, at least as regarded its higher forms. His views met with no favour from scientific men, and he returned to the field of exact research, which he was better qualified to cultivate with advantage. Taking up his residence at St Marychurch, in South Devon, he produced from 1858 to 1860 his standard work on sea-anemones, the *Actinologia Britannica*. *The Romance of Natural History* and other popular works followed, until in 1865 he abandoned the field of authorship. His later years were chiefly devoted to the cultivation of orchids and the study of the Rotifera, upon which, with the assistance of Dr C. T. Hudson, he published a monograph in 1886. He died at Torquay on 23rd August 1888. His life has been written by his son, Mr Edmund Gosse. (R. G.)

Göta.—(1) A river of Sweden, which flows out of the south extremity of Lake Wener, and goes almost due south to the Cattegat, entering it by two arms, one on each side of the island of Hisingen, the east arm flowing past Gothenburg. It is navigable for large vessels throughout its entire course of 47 miles, the famous (four) falls of Trollhätta (108 feet descent in four-fifths of a mile) being avoided by means of the Trollhätta canal, made in 1793–1800, but enlarged and altered in 1838–44. At the village of Trollhätta (population, 5615) there are iron-works, paper and calcium carbide factories, saw-mills, &c. (2) A canal of Sweden, which connects Lake Wener with the Baltic, passing on the way through Lakes Wetter, Boren, Boxen, and numerous smaller ones, giving a waterway 125 miles long (54 miles of artificial cuttings), 47 feet wide at the bottom and 85¼ feet wide at the surface, with a depth of 9 feet 9½ inches, and with 58 locks in all. The canal starts at Sjötorp, on the east side of Wener, enters Lake Wetter at Carlsberg, passes out of it again at Motala, and connects with the Baltic at Mem, 3 miles below Söderköping. It was constructed in 1810–32 by B. B. von Platen, with the assistance of Telford, though the idea dated back to the year 1516. The highest point (300 feet above sea-level) of the canal is in Lake Viken, between Lakes Wener and Wetter. The traffic through the canal has increased to such an extent that the question of enlarging it throughout was forced to the front in 1900.

Gotha, a town of Germany, capital of the grand-duchy of Coburg-Gotha, at the north foot of the Thuringian Forest, 17 miles by rail west from Erfurt. It alternates with Coburg as the grand-ducal residence. The town hall, built in 1574, was restored in 1898. There are monuments to Arnoldi (1778–1841), a benefactor of the town, and of the war of 1870–71. Population (1885), 27,802; (1900), 34,648.

Gothenburg (Swedish *Göteborg*), a seaport town of Sweden, on the east bank of the river Göta, 285 miles south-west from Stockholm by rail. It ranks in respect of industry, commerce, and population as the second city in the kingdom. The industries of Gothenburg produced 10·3 per cent. of the value of the gross output of the entire kingdom in 1895 (Stockholm = 27·4 per cent.). The commerce of Gothenburg in 1895 represented 27·2 per cent. of the aggregate foreign trade of the kingdom, as compared with 19·7 per cent. for Stockholm; the imports amounting to £5,300,000, and the exports to £4,611,000, or an aggregate of £9,911,000. The principal items of export are iron (annual average, nearly 110,000 tons), butter, timber, paper, cereals and flour, matches, wood-pulp, zinc ore, joinery, fish, bottles, bacon, bobbins, and cardboard. Of the imports the most important are textiles, raw cotton, grain and flour, sugar and molasses, coffee, coal, bricks, wines and spirits, and machinery. In 1900 the port was cleared by 2687 vessels of 1,186,500 tons, as compared with 2341 vessels of 845,800 tons in 1885. The harbour in the Göta river is kept open in winter by ice-breakers. In 1893 a new quay, 1530 feet long, was completed, giving 20 feet depth alongside. In 1902 it was proposed to build a new dry dock, 490 feet long and 25 feet deep, so as to accommodate vessels of 6000 to 8000 tons displacement. The merchant fleet numbers about 200 vessels of some 100,000 tons. Gothenburg is the principal port of embarkation of Swedish emigrants for the United States. During the last years of the 19th century this city expanded at a rapid rate. In 1898 it was decided to equip it with modern fortifications. The old East India Company's house, in which the museum has been sheltered since 1861–63, was restored in 1894–96. A university college, with arts faculty, was opened in 1891. Other new buildings are the Oscar Frederick church (1889–93), and an imposing asylum (Gibraltar) for old age (1896). Population (1880), 76,401; (1890), 104,657; (1898), 123,105, or including the widespread suburbs, 130,619. If, as is proposed, Lundby (9730), on the island of Hisingen, on the opposite side of the river, were incorporated with the city, the population would exceed 140,000. Gothenburg is famous for the plan of liquor law reform known as the Gothenburg Licensing System. Although first formally adopted in Gothenburg in 1865, modified forms of the system seem to have been in existence earlier at Falun (1850), Jönköping (1852), and Marstrand. A further modification of the system was adopted in Norway in 1871, but repealed in favour of local option pure and simple in 1894. (See LIQUOR LAWS.) (J. T. BE.)

Gothland (Swedish, *Gotland* and *Götaland*), the southernmost of the three territorial divisions of Sweden. It embraces the counties of Malmöhus, Christianstad,

Blekinge, Halland, Göteborg and Bohus, Kronoberg, Calmar, Jönköping, Elfsborg, Skaraborg, Östergötland, and Gotland (the island of Gothland), with an area of 35,788 square miles. Population (1880), 2,593,621; (1900), 2,696,233. The island of GOTHLAND, between 56° 54′ and 57° 56′ N. lat. and 18° 7′ and 19° 22′ E. long., in the Baltic, about 40 miles from the east coast of Sweden, forms, together with the island of Fårö (39 square miles), Gotska Sandö (about 30 miles north by east, area 14 square miles), and the Charles Islands, a separate county, with an area of 1215 square miles. Population (1880), 54,668; (1900), 52,781. It is a level plateau of Silurian limestone, inclined gently eastwards, with steep coasts, fringed with tapering, columnar, free-standing buttresses of limestone (*raukar*). The climate is mild and the soil fertile. The marshy moorlands (*e.g.*, Martebo) have in recent years been drained and cultivated. In 1897, 19·7 per cent. of the total area was under the plough, 10·7 per cent. meadow land, and 44·5 per cent. forest. There are nearly 80 miles of railway on the island. Perhaps the most characteristic feature of Gothland is the very large number of 13th-century churches, with massive towers, often standing detached, and generally considered to have been built for defensive purposes. (See WISBY.)

Goto Islands (GOTO RETTO), a group of islands belonging to Japan, lying westward of the province of Hizen, in 33° N. lat. and 129° E. long. The southern of the two principal islands, Fukae-jima, measures 17 miles by 13½; the northern, Nakaori-jima, measures 23 miles by 7½. These islands lie almost in the direct route of steamers plying between Nagasaki and Shanghai, and are distant some 50 miles from Nagasaki. Some dome-shaped hills command the old castle-town of Fukae. The islands are highly cultivated; deer and other game abound, and trout are plentiful in the mountain streams. A majority of the inhabitants are Christians.

Göttingen, a town of Prussia, province of Hanover, 67 miles south from Hanover by the railway to Cassel. The battlemented town hall, dating from 1369–71, was restored in 1880. There are a natural history museum, municipal collection of antiquities, picture gallery, agricultural institute, physical institute, institute for physical chemistry and electro-chemistry, provincial lunatic asylum, commercial and technical trade schools; also a monument to the mathematicians Gauss and Weber (1899), and another to the poet Bürger (1895). In 1900 the University was attended by 1314 students, and had 131 professors. Population (1885), 21,561; (1900), 30,234.

Gottschee (Slovene, KOČEVJE), a duchy, government district, and town on the southern border of the Austrian crownland of Carniola—a German enclave in a Slovene province. The *duchy* has an area of over 270 square miles and a population of about 25,000, of whom the majority are "Gottscheer," a people of Franconian and Thuringian origin, who have apparently been settled in the country at least since the 14th century. They have preserved their racial characteristics and dialect, notwithstanding their absolute isolation in a purely Slav country. The duchy lies entirely within the barren limestone region of the Karst. The *government district* has a larger area than the duchy, and a Slovene majority. The *chief town*, on the Rinsee rivulet, which disappears into the earth in the immediate vicinity, has 2421 German inhabitants and a certain amount of trade and industry (wood-carving, turnery, glass, pottery, &c.). The Friedrichstein ice-cave and numerous other caverns in the neighbourhood, with their singular subterranean fauna, attract many visitors.

Goulburn, a town of New South Wales, 134 miles S.W. of Sydney by the Great Southern Railway. It lies in a productive agricultural district, and has an ample water supply. There are Church of England and Roman Catholic cathedrals. The gaol was erected at a cost of £72,000. Manufactures of boots and shoes, flour, and beer, and tanning are important. The altitude is 2129 feet. Population (1881), 6839; (1901), 10,190.

Goulburn, Edward Goulburn (1818–1897), English Churchman, son of Mr Serjeant Goulburn, M.P., Recorder of Leicester, and nephew of the Right Hon. Henry Goulburn, Chancellor of the Exchequer in the Ministries of Sir Robert Peel and the Duke of Wellington, was born in London, 11th February 1818, and educated at Eton and Balliol, Oxford. In 1839 he became fellow and tutor of Merton, and in 1841 was ordained. In 1850 he was chosen to succeed Tait as headmaster of Rugby, but in 1858 he resigned, and in 1859 became vicar of St John's, Paddington. In 1866 he was made Dean of Norwich, and for twenty-three years exercised a marked influence on Church life in that capacity. A strong Conservative and a Churchman of traditional orthodoxy, he was a keen antagonist of "higher criticism" and rationalism in all its varieties. As an author, his *Thoughts on Personal Religion* and *Pursuit of Holiness* were well-known books; and he wrote the *Life* of his friend Dean Burgon, with whose doctrinal views he was substantially in agreement. He resigned the deanery in 1889, and died at Tunbridge Wells on 3rd May 1897.

Gould, Benjamin Apthorp (1824–1896), American astronomer, was born in Boston, Mass., 27th September 1824, the son of Benjamin Apthorp Gould (1787–1859), principal of the Boston Latin School and editor of several classical text-books for schools. Young Gould graduated at Harvard in 1844, and afterwards studied mathematics and astronomy at Göttingen. On his return to America he was employed in the astronomical work of the United States Coast Survey, under Superintendents Bache and Pierce, devoting himself chiefly to longitude determinations, and employing land and submarine telegraphs for the purpose. Between 1849 and 1861 he conducted an *Astronomical Journal*. From 1856 to 1859 he acted as director of the Dudley Observatory at Albany, New York. During the Civil War of 1861–65 he was for a time in charge of the statistics of the Sanitary Commission; but his most important work was done between 1868 and 1885, when he planned a private astronomical expedition to Argentina, for the purpose of extending to the southern hemisphere zone-observations like those of Bessel and Argelander in the northern. The value of his labours was perceived by the Argentine Government, and out of them grew the national observatory at Cordoba, which he organized and from which he issued astronomical reports and maps. Of particular importance is a series of sidereal charts, or uranometry, of the southern heavens (1872–77), in which he practically extended Argelander's scale to the whole heavens. For this service he received the gold medal of the Royal Astronomical Society. Gould had been one of the first to see the use of photography in accurate determination of star-places, having, as far back as 1866, co-operated with L. M. Rutherfurd in photographing the Pleiades. Returning to America in 1885, he re-established his *Astronomical Journal* and engaged in other similar labours until his death in Cambridge, Massachusetts, 26th November 1896.

Gould, Jay (1836–1892), American financier, was born in Roxbury, Delaware county, New York, 27th May 1836. He was brought up on his father's farm, and

studied in Hobart Academy. After some business experience in several states, he removed in 1859 to New York City, where he became a broker in railway stocks, and in 1868 was elected president of the Erie Railroad. The management of this road under his control led to litigation begun by the English bondholders, and Gould was forced out of the company and compelled to restore securities valued at $7,500,000. He had become interested in other railways, and by means of consolidations, reorganizations, and constructing branch lines, built up the "Gould system" in the south-western states. He also gained control of the Western Union Telegraph Company, and after 1880 of the elevated railways in New York City. He was intimately connected with many of the largest railway and financial operations in the United States for the twenty years following 1868, including the panic in the New York gold market on "Black Friday." He was one of the wealthiest men in the United States, and his property aggregated $72,000,000 at the time of his death, which took place in New York City on the 2nd of December 1892.

Gounod, Charles François (1818–1893), French composer, was born in Paris on 17th June 1818, the son of F. L. Gounod, a talented painter. He entered the Paris Conservatoire in 1836, studied under Reicha, Halévy, and Lesueur, and won the "Grand Prix de Rome" in 1839. While residing in the Eternal City he devoted much of his time to the study of sacred music,

Charles Gounod.
(From a photograph by Elliott and Fry.)

notably to the works of Palestrina and Bach. In 1843 he went to Vienna, where a "requiem" of his composition was performed. On his return to Paris he tried in vain to find a publisher for some songs he had written in Rome. Having become organist to the chapel of the "Missions Étrangères," he turned his thoughts and mind to religious music. At that time he even contemplated the idea of entering into holy orders. His thoughts were, however, turned to more mundane matters when, through the intervention of Madame Viardot, the celebrated singer, he received a commission to compose an opera on a text by Émile Augier for the Académie Nationale de Musique. *Sapho*, the work in question, was produced in 1851, and if its success was not very great, it at least sufficed to bring the composer's name to the fore. Some critics appeared to consider this work as evidence of a fresh departure in the style of dramatic music, and Adolphe Adam, the composer, who was also a musical critic, attributed to Gounod the wish to revive the system of musical declamation invented by Gluck. The fact was that *Sapho* differed in some respects from the operatic works of the period, and was to a certain extent in advance of the times. When it was revived at the Paris Opéra in 1884, several additions were made by the composer to the original score not altogether to its advantage, and *Sapho* once more failed to attract the public. Gounod's second dramatic attempt was again in connexion with a classical subject, and consisted in some choruses written for *Ulysse*, a tragedy by Ponsard, played at the Théâtre Français in 1852, when the orchestra was conducted by Offenbach. The composer's next opera, *La Nonne Sanglante*, given at the Paris Opéra in 1854, was a failure.

Goethe's *Faust* had for years exercised a strong fascination over Gounod, and he at last determined to turn it to operatic account. The performance at a Paris theatre of a drama on the same subject delayed the production of his opera for a time. In the meanwhile he wrote in a few months the music for an operatic version of Molière's comedy, *Le Médecin malgré lui*, which was produced at the Théâtre Lyrique in 1858. Berlioz well described this charming little work when he wrote of it, "Everything is pretty, piquant, fluent, in this 'opéra comique'; there is nothing superfluous and nothing wanting." The first performance of *Faust* took place at the Théâtre Lyrique on 19th March 1859. Goethe's masterpiece had already been utilized for operatic purposes by various composers, the most celebrated of whom was Spohr. The subject had also inspired Schumann, Berlioz, Liszt, Wagner, to mention only a few, and the enormous success of Gounod's opera did not deter Boito from writing his *Mefistofele*. *Faust* is without doubt the most popular French opera of the second half of the 19th century. Its success has been universal, and nowhere has it achieved greater vogue than in the land of Goethe. For years it remained the recognized type of modern French opera. At the time of its production in Paris it was scarcely appreciated according to its merits. Its style was too novel, and its luscious harmonies did not altogether suit the palates of those dilettanti who still looked upon Rossini as the incarnation of music. Times have indeed changed, and French composers have followed the road opened by Gounod, and have further developed the form of the lyrical drama, adopting tho theories of Wagner in a manner suitable to their national temperament. Although in its original version *Faust* contained spoken dialogue, and was divided into set pieces according to custom, yet it differed greatly from the operas of the past. Gounod had not studied the works of German masters such as Mendelssohn and Schumann in vain, and although his own style is eminently Gallic, yet it cannot be denied that much of its charm emanates from a certain poetic sentimentality which seems to have a Teutonic origin. Certainly no music such as his had previously been produced by any French composer. Auber was a gay trifler, scattering his bright effusions with absolute *insouciance*, teeming with melodious ideas, but lacking depth. Berlioz, a musical Titan, wrestled against fate with a superhuman energy, and, Jove-like, subjugated his hearers with his thunderbolts. It was, however, reserved for Gounod to introduce *la note tendre*, to sing the tender passion in accents soft and languorous. The musical language employed in *Faust* was new and fascinating, and it was soon to be adopted by many other French composers, certain of its idioms thereby becoming hackneyed. Gounod's opera was given in London in 1863, when its success, at first doubtful, became enormous, and it was heard concurrently at Covent

Garden and Her Majesty's Theatres. Since then it has never lost its popularity.

Although the success of *Faust* in Paris was at first not so great as might have been expected, yet it gradually increased and set the seal on Gounod's fame. The fortunate composer now experienced no difficulty in finding an outlet for his works, and the succeeding decade is a specially important one in his career. The opera from his pen which came after *Faust* was *Philémon et Baucis*, a setting of the mythological tale in which the composer followed the traditions of the Opéra Comique, employing spoken dialogue, while not abdicating the individuality of his own style. This work was produced at the Théâtre Lyrique in 1860. It has repeatedly been heard in London. *La Reine de Saba*, a four-act opera, produced at the Grand Opéra on 28th February 1862, was altogether a far more ambitious work. For some reason it did not meet with success, although the score contains some of Gounod's choicest inspirations, notably the well-known air, "Lend me your aid." *La Reine de Saba* was adapted for the English stage under the name of *Irene*. The non-success of this work proved a great disappointment to Gounod, who, however, set to work again, and this time with better results, *Mireille*, the fruit of his labours, being given for the first time at the Théâtre Lyrique on 19th March 1864. Founded upon the *Mireio* of the Provençal poet Mistral, *Mireille* contains much charming and characteristic music. The libretto seems to have militated against its success, and although several revivals have taken place and various modifications and alterations have been made in the score, yet *Mireille* has never enjoyed a very great vogue. Certain portions of this opera have, however, been popularized in the concert-room. *La Colombe*, a little opera in two acts without pretension, deserves mention here. It was originally heard at Baden in 1860, and subsequently at the Opéra Comique. A suavely melodious *entr'acte* from this little work has survived and been repeatedly performed.

Animated with the desire to give a pendant to his *Faust*, Gounod now sought for inspiration from Shakespeare, and turned his attention to *Romeo and Juliet*. Here, indeed, was a subject particularly well calculated to appeal to a composer who had so eminently qualified himself to be considered the musician of the tender passion. The operatic version of the Shakespearean tragedy was produced at the Théâtre Lyrique on 27th April 1867. It is generally considered as being the composer's second best opera. Some people have even placed it on the same level as *Faust*, but this verdict has not found general acceptance. Gounod himself is stated to have expressed his opinion of the relative value of the two operas enigmatically by saying, "*Faust* is the oldest, but I was younger; *Romeo* is the youngest, but I was older." The luscious strains wedded to the love scenes, if at times somewhat cloying, are generally in accord with the situations, often irresistibly fascinating, while always absolutely individual. The success of *Romeo* in Paris was great from the outset, and eventually this work was transferred to the Grand Opéra, after having for some time formed part of the *répertoire* of the Opéra Comique. In London it was not until the part of Romeo was sung by Jean de Reszke that this opera obtained any real hold upon the English public.

After having so successfully sought for inspiration from Molière, Goethe, and Shakespeare, Gounod now turned to another famous dramatist, and selected Pierre Corneille's *Polyeucte* as the subject of his next opera. Some years were, however, to elapse before this work was given to the public. The Franco-German war had broken out, and Gounod was compelled to take refuge in London, where he composed the "biblical elegy" *Gallia* for the inauguration of the Royal Albert Hall. During his stay in London Gounod composed a great deal and wrote a number of songs to English words, many of which have attained an enduring popularity, such as "Maid of Athens," "There is a green hill far away," "Oh that we two were maying," "The fountain mingles with the river." His sojourn in London was not altogether pleasant, as he was embroiled in lawsuits with publishers. On Gounod's return to Paris he hurriedly set to music an operatic version of Alfred de Vigny's *Cinq-Mars*, which was given at the Opéra Comique on the 5th April 1877 (and in London in 1900), without obtaining much success. *Polyeucte*, his much-cherished work, appeared at the Grand Opéra the following year on 7th October, and did not meet with a better fate. Neither was Gounod more fortunate with *Le Tribut de Zamora*, his last opera, which, given on the same stage in 1881, speedily vanished, never to reappear. In his later dramatic works he had, unfortunately, made no attempt to keep up with the times, preferring to revert to old-fashioned methods.

The genius of the great composer was, however, destined to assert itself in another field—that of sacred music. His friend Camille Saint-Saëns, in a volume entitled *Portraits et Souvenirs*, writes—

> "Gounod did not cease all his life to write for the church, to accumulate masses and motetts; but it was at the commencement of his career, in the *Messe de Sainte Cécile*, and at the end, in the oratorios *The Redemption* and *Mors et Vita*, that he rose highest."

Saint-Saëns, indeed, has formulated the opinion that the three above-mentioned works will survive all the master's operas. Among the many masses composed by Gounod at the outset of his career, the best is the *Messe de Sainte Cécile*, written in 1855. He also wrote the *Messe du Sacré Cœur*, 1876, and the *Messe à la mémoire de Jeanne d'Arc*, 1887. This last work offers certain peculiarities, being written for solos, chorus, organ, eight trumpets, three trombones, and harps. In style it has a certain affinity with Palestrina. *The Redemption*, which seems to have acquired a permanent footing in Great Britain, was produced at the Birmingham Festival of 1882. It was styled a sacred trilogy, and was dedicated to Queen Victoria. The score is prefixed by a commentary written by the composer, in which the scope of the oratorio is explained. It cannot be said that Gounod has altogether risen to the magnitude of his task. The music of *The Redemption* bears the unmistakable imprint of the composer's hand, and contains many beautiful thoughts, but the work in its entirety is not exempt from monotony. *Mors et Vita*, a sacred trilogy dedicated to Pope Leo XIII., was also produced for the first time in Birmingham at the Festival of 1885. This work is divided into three parts, "Mors," "Judicium," "Vita." The first consists of a Requiem, the second depicts the Judgment, the third Eternal Life. Although quite equal, if not superior, to *The Redemption*, *Mors et Vita* has not obtained similar success.

Gounod was a great worker, an indefatigable writer, and it would occupy too much space to attempt even an incomplete catalogue of his compositions. Besides the works already mentioned may be named two symphonies which were played during the 'fifties, but have long since fallen into neglect. Symphonic music was not Gounod's *forte*, and the French master evidently recognized the fact, for he made no further attempts in this style. The incidental music he wrote to the dramas *Les deux Reines* and *Jeanne d'Arc* must not be forgotten. He also attempted to set Molière's comedy, *Georges Dandin*, to

music, keeping to the original prose. This work has never been brought out. Gounod composed a large number of songs, many of which are very beautiful. One of the vocal pieces that have contributed most to his popularity is the celebrated *Meditation on the First Prelude of Bach*, more widely known as the *Ave Maria*. The idea of fitting a melody to the Prelude of Bach was original, and it must be admitted that in this case the experiment was successful.

Gounod died at St Cloud on the 18th of October 1893. His influence on French music was immense, though during the last years of the 19th century it was rather counterbalanced by that of Wagner. Whatever may be the verdict of posterity, it is unlikely that the quality of individuality will be denied to Gounod. To be the composer of *Faust* is alone a sufficient title to lasting fame. (A. He)

Gourko, Joseph Vladimirovitch, Count (1828–1901), Russian general, was born, of Lithuanian extraction, on the 15th of November 1828. He was educated in the Imperial *Corps de Pages*, entered the Hussars of the Imperial Body Guard as sub-lieutenant in 1846, became captain in 1857, adjutant to the Emperor in 1860, colonel in 1861, commander of the 4th Hussar regiment of Mariupol in 1866, and major-general of the Emperor's suite in 1867. He subsequently commanded the grenadier regiment, and in 1873 the 1st brigade, 2nd division, of the cavalry of the guard. Although he took part in the Crimean war, being stationed at Belbek, his claim to distinction is due to his services in the Turkish war of 1877. He led the van of the Russian invasion, took Trnovo on the 7th July, crossed the Balkans by the Hain Bogaz pass, debouching near Hainkioi, and, notwithstanding considerable resistance, captured Uflani, Maglish, and Kezanlyk; on the 18th July he attacked Shipka, which was evacuated by the Turks on the following day. Thus within sixteen days of crossing the Danube Gourko had secured three Balkan passes and created a panic at Constantinople. He then made a series of successful reconnaissances of the Tunja valley, cut the railway in two places, occupied Eski and Yeni Saghra, checked the advance of Suleiman's army, and returned again over the Balkans. In October he was appointed commander of the allied cavalry, and attacked the Plevna line of communication to Orkhanie with a large mixed force, captured Gorni-Dubnik, Telische, and Vratza, and, in the middle of November, Orkhanie itself. Plevna was isolated, and after its fall in December Gourko led the way amidst snow and ice over the Balkans to the fertile valley beyond, totally defeated Suleiman, and occupied Sophia, Philippopolis, and Adrianople, the armistice at the end of January 1878 stopping further operations. Gourko was made a count, and decorated with the 2nd class of St George and other orders. In 1879–80 he was Governor of St Petersburg, and from 1883 to 1894 Governor-General of Poland. He died on 29th January 1901. (R. H. V.)

Gourock, a police burgh and watering-place of Renfrewshire, Scotland, on the southern shore of the Firth of Clyde, 3¼ miles west of Greenock by rail. There is an extensive pier, and the bay affords good anchorage for yachts. The Gamble Institute includes recreation rooms, public library, and baths; and there are three excellent bowling greens. There is tramway communication with the suburb of Ashton, finely situated on the hillside facing the Firth of Clyde, and commanding magnificent views of the Argyllshire Highlands and the famous salt-water lochs. Population (1881), 3336; (1901), 5244.

Gout. See Pathology (*Metabolic Diseases*).

Govan, a police burgh of Lanarkshire, Scotland, on the south bank of the Clyde adjacent to Glasgow, and in a parish of the same name which includes a large part of the city. Govan remained little more than a village till about 1860, when the growth of shipbuilding and allied trades on the Clyde gave its development an impetus which is not yet exhausted. It was formed into a police burgh in 1864, and the police commission is now in occupation of its third set of municipal chambers (costing £40,000); there are also a theatre (1899) and a combination fever hospital. The Elder Park, presented to the burgh in 1885, contains a statue of John Elder, the pioneer shipbuilder, the husband of the donor. A statue of Sir William Pearce, another well-known Govan shipbuilder and once M.P. for the burgh, stands at Govan Cross. The Govan Lunacy Board opened in 1896 a new asylum near Paisley. Govan is supplied with Glasgow gas and water, and its tramways are leased by the Glasgow Corporation; but it has an electric light installation of its own (1899), and performs all other municipal functions quite independently of the city, annexation to which it has always strenuously resisted. Four of the shipbuilding yards noticed under Glasgow are situated in the burgh, and its other industries are match-making, silk-weaving, hair-working, copper-working, tube-making, weaving, and the manufacture of locomotives and electrical apparatus. The town forms the greater part of the Govan division of Lanarkshire, which returns a member to Parliament. Area, 1069 acres. Population (1901), 76,351.

Government. See Politics.

Gowreeshankar Vodeyshankar (1805–1892), native minister and (during the minority of the prince, Sir Takht Singhji) joint administrator of the State of Bhaunagar in Kathiawar, was born on the 21st August 1805 at the seaport town of Gogo, in a respectable, though not affluent, family of Nagar Brahmans. After receiving the ordinary education of those rude unsettled times, he, in 1822, was appointed to assist Mr Shevakram Desai, the vakil or representative of the Bhaunagar State at the Political Agency for Kathiawar, just then established by the Bombay Government. In a short time he became a revenue officer, and successfully resisted some exorbitant claims made against the State in the British courts. In 1847 his services were acknowledged by the Thakoresaheb Vaje Singhji, who promoted him to be joint *karbhari*, or State minister, in association with Desai Suntokeram Sheorkeram. The reforming hand was soon felt. Old complaints made by the British Agent were disposed of, and the punitive fines called *moshul*, which then cost the Durbar Rs.18,000 a year, were terminated. A claim on seventy-six villages made by the Nawab of Junagarh was settled by a money payment. An Arab Jamedar, a sort of a military commandant, had also a claim for 72 lakhs of rupees as guarantor of debts incurred by a former chief. As security for payment this subject had got possession of the fine district of Mahuwa. Colonel Lang, the Political Agent, intervened, an account was taken, and the claim being reduced to 3½ lakhs was paid off, and the territory recovered, not without imminent risk of bloodshed. Gowreeshankar was also the moving spirit of the diplomacy which in 1866 led the British Government to restore to Bhaunagar the jurisdiction over 116 villages which had been treated as British from the year 1816. The tribute also to be paid to the British Government by the State, which was increasing every year, was permanently settled at Rs.52,000. Similar activity was shown in internal affairs. Judicial regulations were passed, public works undertaken, and education was promoted by an

Anglo-vernacular school. Even female education was fostered. The reigning chief, Juswant Singhji, who had received the honour of K.C.S.I., dying in 1870, Gowreeshankar took charge of the State pending an arrangement by which Mr E. H. Percival, chosen from the Bombay civil service on account of his great experience and even temper, was joined with him to exercise the powers of the Chief, then a minor. The experiment was in every respect successful. Under the simple and economical forms used in native States, improvements suggested by British Indian experience were introduced. The land revenue was based on a cash system, the fiscal and customs systems were remodelled, and tree planting was encouraged. The town of Bhaunagar received the great boon of the Gowreeshankar Waterworks, on which 6 lakhs of rupees were spent. The Percival Markets too were built. The Bhaunagar State also warmly pressed for railway communication with the continent of India, and thus began a movement which has spread a network of railway lines over the peninsula of Kathiawar. The British Government rewarded these many services of Gowreeshankar with the distinction of C.S.I. in 1877. He helped to establish the Rajkumar College at Rajkot, for the education of native princes, and also the Rajasthanik Court, which, after settling almost innumerable disputes between the land-owning classes and the chiefs, has since been abolished. On the 13th January 1879 Gowreeshankar resigned office, after a service of fifty-five years, and devoted himself absolutely to the study of the higher literature of that Vedanta philosophy which through his whole life had been to him a solace and a guide. In 1884 he wrote a work called *Svarupanusandhan*, on the union of the soul with Deity, which led to a letter of warm congratulation and regard from Max Müller, who also published a short biography of him. In 1887 he put on the robe of the *Sanyasi* or ascetic, the fourth stage, according to the Hindu Shastrus, in the life of the twice-born man, and in this manner passed the remainder of his life, giving above ten hours each day to Vedantic studies and holy contemplations. He died, revered by all classes, in December 1892. Born before the first intervention of the British in the affairs of Kathiawar, Gowreeshankar was acquainted with all the events that followed the settlement made by Colonel A. Walker in 1808. Trained among the Nagar Brahmans, who have supplied many ministers to the princely houses of the peninsula, his career was that of a statesman, devoid of English education and essentially Hindu in mind and tastes and methods. His influence was great with the ministers of the neighbouring States. His advice was at all times valued by the British officers, who publicly honoured his ability, his prudence, and his integrity, and ever treated him with the highest consideration and deference. (N. B. W.)

Goyaz, a state of Brazil, having on the N. Pará and Maranhao, on the W. Matto Grosso and Pará, on the S. Minas Geraes and S. Paulo, and on the E. Maranhao, Piauhy, Minas Geraes, and Bahia. Area, 288,546 square miles. Population (1890), 227,572. The capital, Goyaz, on the Rio Vermelho, has 3000 inhabitants; other towns are Boa Vista, Bomfim, Entre Rios, Formosa, Porto Nacional, &c.

Graaff Reinet, a town of Cape Colony, on the Upper Sunday river, which rises a little farther north on the southern slopes of the Sneeuwbergen, and here ramifies into several channels flowing through the surrounding fields and gardens. The town is one of the oldest Dutch settlements in the interior of the colony, dating from the latter part of the 18th century, and is the present inland terminus of a serpentine railway which runs from Port Elizabeth through Uitenhage northwards nearly to the sources of the Sunday river. Graaff Reinet is a flourishing market for the local agricultural produce. Population (1891), 5946.

Grabow, a town of Prussia, province of Pomerania, on the left bank of the Oder, immediately north of Stettin, of which it is now a suburb, with important industries. Its parish church dates from 1890, and it has a school of navigation. Population (1885), 14,541; (1900), 22,583.

Grace, William Gilbert (1848– ——), English cricketer, was born at Downend, in Gloucestershire, on 18th July 1848. He early found himself in an atmosphere charged with cricket, his father (Henry Mills Grace) and his uncle (Alfred Pocock) being as enthusiastic over the game as his elder brothers, Henry, Alfred, and Edward Mills; indeed, in E. M. Grace the family name first became famous. A younger brother, George Frederick, also added to the cricket reputation of the family. "W. G." witnessed his first great match when he was hardly six years old, the occasion being a game between W. Clarke's All-England Eleven and twenty-two of West Gloucestershire. When he grew up, he was endowed by nature with a splendid physique as well as with powers of self-restraint and determination. At the acme of his career he stood full 6 feet 2 inches, being powerfully proportioned, loose yet strong of limb. A non-smoker, and very moderate in all matters, he kept himself in condition all the year round, shooting, hunting, or running with the beagles as soon as the cricket season was over. He was also a fine runner, 440 yards over 20 hurdles being his best distance; and it may be quoted as proof of his stamina that on 30th July 1866 he scored 224 not out for England *v.* Surrey, and two days later won such a race in the National and Olympian Association meeting at the Crystal Palace. He speedily made his name a household word wherever the game of cricket was a matter of interest. The title of "champion" was well earned by one who for a space of thirty-six years (1865–1900 inclusive) was actively engaged in first-class cricket. In no one of these years was he not invited to represent the Gentlemen in their matches against the Players, or, when an Australian eleven visited England, to play for the mother country against her colony. As late as 1899 he played in the first of the five international contests; in 1900 he played against the Players at the Oval, scoring 58 and 3. At the age of fifty-three, he scored nearly 1300 runs in first-class cricket, made 100 runs and over on three different occasions, and could claim an average of 42 runs. Moreover, his greatest triumphs were achieved when only the very best cricket grounds received serious attention, when, as some consider, bowling was maintained at a higher standard, and when all hits had to be run out. He, with his two brothers, E. M. and G. F., assisted by some fine amateurs, made Gloucestershire in one season a first-class county; and it was he who first enabled the amateurs of England to meet the paid players on equal terms, and to beat them. There is hardly a "record" connected with the game which has not at some time or another stood to his credit. Dr Grace did not, however, "specialize" in batting; he was at all times one of the finest fieldsmen in England, in his earlier days generally taking long-leg and cover-point, in later times generally standing point when he was not bowling. He was, at his best, a fine thrower, fast runner, and safe "catch." As a bowler he was long in the first flight, originally bowling fast, but in later times adopting a slower and more tricky style, which, from his intimate knowledge of

the game, was frequently very effective. By profession he was a medical man. In later years he became secretary and manager of the London County Cricket Club. He was married in 1873 to Miss Agnes Day, and one of his sons played for two years in the Cambridge eleven. He has been the recipient of two national testimonials: the first, amounting to £1500, being presented to him in the form of a clock and a cheque at Lord's ground by Lord Charles Russell, on 22nd July 1879; the second, collected by the M.C.C., the county of Gloucestershire, the *Daily Telegraph*, and the *Sportsman*, amounted to about £10,000, and was presented to him in 1896. He visited Australia in 1873–74 (captain), and in 1891–92 with Lord Sheffield's Eleven (captain); America and Canada in 1872, with R. A. Fitzgerald's team.

Dr Grace played his first great match in 1863, when, being only fifteen years of age, he scored 32 against the All-England Eleven and the bowling of Jackson, Tarrant, and Tinley; but the scores which first made his name prominent were made in the next year, viz., 170 and 56 not out for the South Wales Club against the Gentlemen of Sussex. It was in 1865 that he "first took an active part in first-class cricket," being then seventeen years of age, 6 feet in height, and 11 stone in weight, and playing twice for the Gentlemen *v.* the Players, but his selection was mainly due to his bowling powers, the best exposition of which was his aggregate of 13 wickets for 84 runs for the Gentlemen of the South *v.* the Players of the South. His absolutely highest score was 400 not out, made in July 1876 against twenty-two of Grimsby; but on three occasions he was twice dismissed without scoring in matches against odds, a fate that never befell him in important cricket. In first-class matches his highest score was 344, made for the M.C.C. *v.* Kent at Canterbury, in August 1876: two days later he made 177 for Gloucestershire *v.* Notts, and two days after this 318 not out for Gloucestershire *v.* Yorkshire, the two last-named opposing counties being possessed of exceptionally strong bowling; thus in three consecutive innings Dr Grace scored 839 runs, and was only got out twice. His 344 is the third highest individual score made in a big match in England up to the end of 1901. He also scored 301 for Gloucestershire *v.* Sussex at Bristol, in August 1896. He made over 200 runs on ten occasions, the most notable perhaps being in 1871, when he performed the feat twice, each time in benefit matches, and each time in the second innings, having been each time got out in the first over of the first innings. He scored over 100 runs on 121 occasions, the hundredth score being 288, made at Bristol for Gloucestershire *v.* Somersetshire in 1895. He made every figure from 0 to 100, on one occasion "closing" the innings when he had made 93, the only total he had never made between these limits. In 1871 he made no fewer than ten "centuries," ranging from 268 to 116. In the matches between the Gentlemen and Players he scored "three figures" fifteen times, and at every place where these matches have been played. He made over 100 in each of his "first appearances" at Oxford and Cambridge. Three times he made over 100 in each innings of the same match, viz., at Canterbury, in 1868, for South *v.* North of the Thames, 130 and 102 not out; at Clifton, in 1887, for Gloucestershire *v.* Kent, 101 and 103 not out; and at Clifton, in 1888, for Gloucestershire *v.* Yorkshire, 148 and 153. In 1869, playing at the Oval for the Gentlemen of the South *v.* the Players of the South, Dr Grace and B. B. Cooper put on 283 runs for the first wicket, Dr Grace scoring 180 and Cooper 101. In 1886 he and Scotton put on 170 runs for the first wicket of England *v.* Australia; this occurred at the Oval in August, and Dr Grace's total score was 170. In consecutive innings against the Players from 1871 to 1873 he scored 217, 77 and 112, 117, 163, 158, and 70. He only twice scored over 100 in a big match in Australia, nor did he ever make 200 at Lord's, his highest being 196 for the M.C.C. *v.* Cambridge University in 1894. His highest aggregates were 2739 (1871), 2622 (1876), 2346 (1895), 2139 (1873), 2135 (1896), and 2062 (1887). He scored three successive centuries in first-class cricket in 1871, 1872, 1873, 1874, and 1876. Playing against Kent at Gravesend in 1895, he was batting, bowling, or fielding during the whole time the game was in progress, his scores being 257 and 73 not out. He scored over 1000 runs and took over 100 wickets in seven different seasons, viz., in 1874, 1665 runs and 129 wickets; in 1875, 1498 runs, 192 wickets; in 1876, 2622 runs, 124 wickets; in 1877, 1474 runs, 179 wickets; in 1878, 1151 runs, 153 wickets; in 1885, 1688 runs, 118 wickets; in 1886, 1846 runs, 122 wickets. No one else has performed this feat more than twice, except G. Giffen, the Australian. He never captured 200 wickets in a season, though he came very near to the feat in 1875 with 192. Playing against Oxford University in 1886, he took all the wickets in the first innings, at a cost of 49 runs. In 1895 he not only made his hundredth century, but actually scored 1000 runs in the course of the month of May alone, his chief scores in that month being 103, 288, 256, 73, and 169, he being then forty-seven years old. He also made during that year scores of 125, 119, 118, 104, and 103 not out, his aggregate for the year being 2346, and his average 51; his innings of 118 was made against the Players (at Lord's), the chief bowlers being Richardson, Mold, Peel, and Attewell; he scored level with his partner, A. E. Stoddart (his junior by fifteen years), the pair making 151 before a wicket fell, Grace making in all 118 out of 241. This may fairly be considered one of his most wonderful years. In 1898 the match between Gentlemen *v.* Players was, as a special compliment, arranged by the M.C.C. committee to take place on his birthday, and he celebrated the event by scoring 43 and 31 not out, though handicapped by lameness and an injured hand. In twenty-six different seasons he scored over 1000 runs, in three of these years being the only man to do so, and five times being one out of two. His first three-figure innings was 244 not out, made at the Oval, July 30 and 31, 1866, for England *v.* Surrey; his last, 126, made at Lord's, 13th September 1900, for South *v.* North.

During the thirty-six years which may be taken as covering his cricket career he scored nearly 51,000 runs, with an average of 43; and in bowling he took more than 2800 wickets, at an average cost of about 20 runs per wicket. He made his highest aggregate (2739 runs) and had his highest average (78) in 1871; his average for the decade 1868–77 was 57 runs, a marvellously fine record for so long a period, when the bowling was splendid and grounds were often rough, while, boundaries being only occasionally used, the majority of the runs had to be run out. It may be added as a matter of interest that he has thrown the cricket ball more than 116 yards, and has hit it a measured distance of 140 yards from the pitch. This latter distance he has probably exceeded. His style as a batsman was more commanding than graceful, but as to its soundness and efficacy there were never two opinions; the severest criticism ever passed upon his powers was to the effect that he did not play slow bowling quite as well as fast.

Grafton, a town in the county of Clarence, New South Wales, Australia, on both sides of the Clarence river, at a distance of 45 miles from its mouth, 342 miles N.E. of Sydney by sea. It comprises two sections, North Grafton and South Grafton, now forming separate municipalities; communication between the two is maintained by a ferry. The river is navigable from the sea to the town for ships of moderate burden, and for small vessels to a point 35 miles beyond it. Extensive harbour works are now in progress at the river mouth. The dairy interest is of growing importance, and the agricultural prospects are good. In the district are several large sugar mills. The mean rainfall is 33·83 inches. Population (1881), 3891; (1901), 4174; South Grafton, 976.

Grafton, capital of Taylor county, West Virginia, U.S.A., on the Tygart Valley river and on two lines of the Baltimore and Ohio Railway. It has large railway shops and several iron foundries. Population (1890), 3159; (1900), 5650, of whom 226 were foreign-born.

Graham, Sir Gerald (1831–1899), English soldier, only son of Dr Robert Hay Graham of Eden Brows, Cumberland, was born on 27th June 1831 at Acton, Middlesex, educated at Dresden and Woolwich Academy, and entered the Royal Engineers in 1850. He served with distinction through the Russian war of 1854 to 1856, was present at the battles of Alma and Inkerman, was twice wounded in the trenches before Sebastopol, and was awarded the Victoria Cross for gallantry at the attack on the Redan and for devoted heroism on numerous occasions (medal with three clasps, Turkish medal, 5th class Legion of Honour, 5th class Medjidie, and brevet majority). In the China war of 1860 he took part in the actions of Sin-ho and Tang-ku, the storming of the Taku Forts, where he was severely wounded, and the entry into Peking (medal with two clasps, brevet lieutenant-colonelcy, and C.B.). Promoted colonel in 1869, he was employed in routine duties until 1877, when he was appointed assistant-director of works for barracks at the War Office, a position he held until his promotion

to major-general in 1881. In command of the advanced force in Egypt in 1882, he bore the brunt of the fighting, was present at the action of Magfar, commanded at the first battle of Kassassin, took part in the second, and led his brigade at the storming of Tel-el-Kebir (medal with clasp, bronze star, 2nd class Medjidie, K.C.B., and thanks of Parliament). In 1884 he commanded the expedition to the Eastern Sudan, and fought the successful battles of El Teb and Tamai, but was forbidden to march to General Gordon's assistance *viâ* Berber, and returned home (two clasps to medal, 1st class Medjidie, thanks of Parliament, lieutenant-general for distinguished service in the field). In 1885 he commanded the Suakin expedition, defeated the Arabs at Hashin and Tamai, and advanced the railway from Suakin to Otao, when the expedition was withdrawn (thanks of Parliament and G.C.M.G.). In 1896 he was made G.C.B., and in 1899 colonel-commandant Royal Engineers. He died on 17th December 1899. He published in 1875 a translation of Goetze's *Operations of the German Engineers in 1870–71*, and in 1887 *Last Words with Gordon.* (R. H. V.)

Graham's Town, a city of Cape Colony, the administrative centre for the Eastern Provinces. It lies 1760 feet above sea-level in a remarkably healthy district, a short distance N. by W. of Port Alfred, and N.E. of Port Elizabeth, with both of which places it is connected by rail. It is one of the earliest English settlements in the colony, dating from the year 1812, and was the chief military station towards Great Fish river during the Kaffir wars. Owing to the sour quality of the herbage in the surrounding "Zuurveld" district, stock-breeding and wool-growing, formerly the chief occupation of the settlers, have in recent years been largely replaced by ostrich-farming, for which industry Graham's Town is the most important centre. Its chief seaward outlet is PORT ALFRED, at the mouth of the little river Kowie, where extensive harbour works now give access to vessels drawing 8 or 10 feet. The great majority of the population is of British descent, and numbered 10,500 in 1891.

Grain Coast. See LIBERIA.

Grain Trade.—The complexity of the conditions of life at the opening of the 20th century may be well illustrated from the mutations of a penny roll. To think that such a common household necessary as a loaf of bread, which in a simpler state of society each family made at home from grain grown in its own patch of land, should have called into existence fleets of ocean and lake steamers, giant railway waggons, mammoth warehouses, and colossal mills, is a good illustration of the distance which we have travelled; moreover, when it is considered that all this progress has been made, say, since 1850, it may be seen what giant strides civilization is now taking. Contrast the cargo of the leviathan ocean tramp of to-day with the freight of a mediæval coaster; the one carrying in a single voyage the whole crop of an entire English county, such as Derbyshire, the other a load of perhaps a hundred tons. Or compare a modern freight car of North America, with its burden of a thousand or thirteen hundred bushels, with the farmer's waggon of 1880; or the latest American canal barge of 4000 tons capacity with its prototype drawn by a bargee or mule. Or, again, take a farmer's barn of the last generation and place it alongside the grain storage silos in Liverpool, which are capable of holding 3,000,000 bushels, the annual produce of one of the larger English counties. Last, but not least significant, is the wonderful development in the appliances for milling wheat. Think of the ancient quern or the picturesque windmill, and compare it with a modern roller flour mill, with, for instance, a stately building like the Chancellot Mills at Edinburgh, or with one of those colossal fabrics that has an endless series of machines, and miles upon miles of pipes and elevators, and is equipped with machinery of such scientific accuracy as to be capable of distinguishing between the fineness of two particles of flour, which together would be barely palpable; mills with a capacity to produce a million sacks per annum, sufficient to feed a city of 10,000 inhabitants for a hundred years.

General considerations.

The origin of wheat is shrouded in mystery. It is alleged to have been found growing wild somewhere between the Euphrates and the Tigris; but the discovery has never been authenticated, for, unless the plant be sedulously cared for, the species dies out in a surprisingly short space of time. Recent experiments in cross-fertilization in Lancashire by the Garton Brothers have evolved the most extraordinary, not to say monstrous, "sports," showing, it is claimed, that in the course of development the plant has probably passed through stages of which until the present day we have not had the slightest conception. The tales that grains of wheat found in the cerements of Egyptian mummies have been planted and come to maturity are no longer credited, for the vital principle in the wheat berry is extremely evanescent; indeed, it is doubtful whether wheat twenty years old is capable of reproduction. The Garton artificial fertilization experiments have shown that endless deviations from the ordinary type can be evolved, ranging from minute seeds with a closely adhering husk to big berries almost as large as sloes and about as worthless. The author of the experiment in question is reported to be of the opinion that the wheat plant, as we know it now, is a degenerate form of something much finer which flourished thousands of years ago, and that it is not unreasonable to look forward to a time when it will be restored to its pristine excellence, yielding an increase twice or thrice as large as that to which we are now accustomed, and thus postponing to a distant period the famine doom prophesied by Sir W. Crookes in his presidential address to the British Association in 1898 (see CROOKES). It is certainly remarkable what latent possibilities seem to lurk in this seed of the *Triticum vulgare*, and how readily it yields them as rewards to man for his research and labour. Contrast the produce of a carelessly tilled Russian or Indian field and the bountiful yield on a good Lincolnshire farm, the former with its average yield of 8 bushels, the latter with its 50 bushels per acre; or compare the quality, as regards the quantity and flavour of the flour from a fine sample of British wheat, such as is on sale at almost every agricultural show in Great Britain, with the produce of an Egyptian or Syrian field; the difference is so great as to cause one to doubt whether the berries are of the same species.

The ordinary loaf which one sees in a baker's shop in Great Britain may be said to represent the product of nearly every country in both hemispheres outside of the tropics, each of the five divisions of the world contributing its share. It may be stated roundly that an average quartern loaf in Great Britain is made from wheat grown in the following countries in the proportions named :—

U.S.A.	U.K.	Russia.	Argentina.	British India.	Canada.	Rumania-Bulgaria.	Australia.	Other Countries.
Oz. 26	Oz. 13	Oz. 9	Oz. 5	Oz. 4	Oz. 3	Oz. 2	Oz. 1	Oz. 1
Or expressed in percentages as follows :—								
40	20	14	8	6	5	3	2	2

Wheat, the great staple food of the most progressive portion of mankind, occupies of all cereals the widest region of any foodstuff. Rice, which shares with millet the distinction of being the principal foodstuff of the greatest number of human beings, is not grown nearly as widely as the white man's favourite cereal. Wheat grows as far south as Patagonia, and as far north as the edge of the Arctic Circle; it flourishes throughout Europe, and across the whole of Northern Asia and in Japan; it is cultivated in Persia, and raised largely in India, as far south as the Nizam's dominions. It is grown in almost every state of the American Union, from Southern California to the State of Washington. In the Dominion of Canada a very fine wheat crop was raised in the autumn of 1898 as far north as the mission at Fort Providence, on the Mackenzie river, in a latitude above 62°—the latitude of the Faroe Islands, or less than 200 miles south of the latitude of Dawson City—the period between seed-time and harvest having been ninety-one days. In Africa we hear of it as an article of commerce in the days of the patriarch Jacob, whose son Joseph may be said, in the parlance of the corn market, to have run the first and only successful "corner" in the staff of life. For many centuries Egypt was famous as a wheat raiser; it was a cargo of wheat from Alexandria which the Apostle St Paul helped to jettison on the occasion of one of his shipwrecks, as was also, in all probability, that of the "ship of Alexandria whose sign was Castor and Pollux," named in the same narrative. General Gordon is quoted as having stated that the Sudan when properly settled would be capable of feeding the whole of Europe. It is known that the cereal flourishes on all the high plateaux of South Africa, from Cape Town to the Zambezi. Additional land is being rapidly and extensively put under wheat in the pampas of South America and in the prairies of Siberia. There are tracts along the north coast of Africa which, if properly irrigated, as was done in the days of Carthage, and as is done in India under British rule to-day, could produce a sufficiency of wheat to feed half of the Caucasian race. For an instance, the vilayet of Tripoli, with an area of 400,000 square miles, or three times the extent of Great Britain and Ireland, according to the opinion of a British consul could raise millions of acres of wheat.

In the raising of the standard of farming to an English level the volume of the world's crop would be trebled, another fact which Sir William Crookes seems to have overlooked. Or, again, take the experiments of the late Sir J. B. Lawes in Hertfordshire, which have proved that the natural fruitfulness of the wheat plant can be increased threefold by the application of the proper fertilizer. A brief digest of the principal results of these most valuable experiments (see also under AGRICULTURE) may not be out of place here. It is taken from a compendium issued from the Rothamsted Agricultural Experimental Station.

Experiment on the growth of wheat year after year on the same land: without manure, and with different descriptions of manure.

Average 46 years. 1852 to 1897.

	Dressed Grain.		Total Straw.
	Quantity. Bushels per Acre.	Weight. Per Bushel, lb.	Per Acre. Cwts.
Unmanured continuously	12⅞	58⅝	9⅜
Farmyard manure . .	35¼	60½	33
Mixed mineral manure (most successful instance) . .	36¾	59⅞	40⅛

Experiment on wheat alternated with fallow and wheat grown continuously.

(Area under experiment 1 acre.)

Averages—Produce after fallow reckoned at the yield per acre, of the half in crop, each year.

	Yield. Bushels per Acre.	Weight per Bushel, lb.	Total Grain, lb.	Total Straw, lb.	Total Grain and Straw, lb.
Wheat after fallow each year .	17⅜	58·7	1073	1595	2668
Wheat after wheat each year .	12¾	58·8	795	1127	1921

It should be noticed that, if after fallow had been reckoned at the yield per acre of the whole area, half in crop and half fallow, the results would of course have been very different. "The conclusion to be drawn is that although there is an increase of produce after fallow compared with that of wheat grown continuously, it is obtained at the sacrifice of a crop every other year, and that a given area of land yields more when the crop is grown year after year, than when alternated with fallow. The explanation doubtless is, that much of the nitrogen brought into an available condition under the influence of the fallow is lost by drainage during the long period that the land is without a crop." This conclusion would seem to be in direct conflict with the advice given to the Israelites of old, and with the practice of many agriculturists abroad at the present time.

As far as can be traced in the report to the Lawes Agricultural Trust Committee by Sir J. H. Gilbert, F.R.S., the highest yield per acre in the twelve years 1871–82 was obtained in the year 1874 with Rivett's (red), the manures used being nitrate after mangels (with dung) were carted off, the yield per acre amounting to 67 bushels of dressed grain; the natural weight, however, was only 58⅛ lb per bushel, the same class of wheat again in 1878 giving 66⅛ bushels of 58⅞ lb natural weight. But in the wet season of 1879 the same seed gave only 16 bushels, weighing 49⅛ lb. Taken over an eight years period, 1871 to 1878, some of the best- and worst-yielding sorts were the following:—

	Total Weight, lb.	Yield per Acre. Bushels.	Weight per lb.
(1) Rivett's (red)	3189	52½	60¾
(2) Belgian (white) . . .	3150	53⅝	58¾
(3) Original red Halletts . .	2302	37⅛	62
(4) White Chiddam . . .	2167	36½	59⅜

The palm for a high natural weight must be awarded to Red Nursery, which on an eight years average scored 63⅛ lb, and for a single year as high as 66 lb (in 1876).

In these comparisons of one class of seed wheat with another, we do not purpose drawing invidious distinctions; indeed, it is by no means the wheat which yields the greatest number of bushels per acre which is the most valuable from a miller's standpoint, for in his estimation the thinness of the bran and the fineness and strength of the flour are most important considerations, too often overlooked by the farmer when buying his seed. But after all, it is the deficient quantity of the wheat raised of late years in the British Islands, and not the quality of the grain, which has been the cause of so much anxiety to economists and statesmen.

Sir J. Caird, writing as recently as in the year 1880, expressed the opinion that arable land in Great Britain would always command a substantial rent of at least 30s. per acre, for he calculated that the cost of carriage from

abroad of wheat, or the equivalent of the product of an acre of good wheat land in Great Britain, would not be less than 30s. per ton. But freights had come down by the year 1900 to half the rates predicated by that authority; indeed, during a portion of the interval they ruled very close to zero, as far as steamer freights from America were concerned. In 1900 an all-round freight rate for wheat might be taken at 15s. *per ton* (a ton representing approximately the produce of an acre of good wheat land in England), say from 10s. for Atlantic American and Russian, to 30s. for Pacific American and Australian; about midway between these two extremes we find Indian and Argentine, the greatest bulk coming at about the 15s. rate. Inferior land bearing less than 4½ quarters per acre would not of course be protected to the same extent, and moreover, seeing that a portion of the British wheat crop has to stand a charge as heavy for land carriage across a county as that borne by foreign wheat across a continent or an ocean, the protection is not nearly so substantial as Caird would make out. The compilation showing the changes in the rates of charges for the railway and other transportation services issued by the Division of Statistics, Department of Agriculture, U.S.A. (Miscellaneous Series, Bulletin No. 15, 1898), is a valuable reference book. From its pages are culled the following facts relating to the changes in the rates of freight up to the year 1900. In Table 3 the average rates per ton per mile in cents are shown since 1846. For the Fitchburg Railroad the rate for that year was 4·523 cents per ton per mile, since when a great and almost continuous fall has been taking place, until in 1897, the latest year given, the rate had declined to ·870 of a cent per ton per mile. The railway which shows the greatest fall is the Chesapeake and Ohio, for the charge has fallen from over 7 cents in 1862 and 1863 to ·419 of a cent in 1897, whereas the Erie rates have fallen only from 1·948 in 1852 to ·609 in 1897. Lumping the rates of the twelve returning railways together, we find the average freight in the two years 1859–60 was 3·006 cents per ton per mile, and that in 1896–97 the average rate had fallen to ·797 of a cent per ton per mile. This difference is very large when the smallness of the unit is borne in mind. Coming now to the *raison d'être* of this inquiry, viz., the rates on grain, we find (in Table 23) a record for the forty years 1858–97 of the charge on wheat from Chicago to New York, *vià* all rail from 1858, and *vià* lake and rail since 1868, the authority being the secretary of the Chicago Board of Trade. From 1858 to 1862 the rate varied between 42·37 and 34·80 cents per bushel for the whole trip of roundly 1000 miles, the average rate in the quinquennium being 38·43. In the five years immediately prior to the time at which Sir J. Caird expressed the opinion that the cost of carriage from abroad would always protect the British grower, the average all-rail freight from Chicago to New York was 17·76 cents, while the summer rate (partly by water) was 13·17 cents. These rates in 1897, the last year shown on the table, had fallen to 12·50 and 7·42 respectively. The rates have been as follows in quinquennial periods, *vià* all rail:—

Freight rates.

Chicago to New York in Cents per Bushel.

1858–62.	1863–67.	1868–72.	1873–77.	1878–82.	1883–87.	1888–92.	1893–97.
38·43	31·42	27·91	21·29	16·77	14·67	14·52	12·88

Calculating roundly a cent as equal to a halfpenny, and eight bushels to the quarter, the above would appear in English currency as follows:—

Chicago to New York in Shillings and Pence per Quarter.

1858–62.	1863–67.	1868–72.	1873–77.	1878–82.	1883–87.	1888–92.	1893–97.
s. d. 12 8	s. d. 10 6	s. d. 9 3	s. d. 7 1	s. d. 5 7	s. d. 4 10½	s. d. 4 10	s. d. 4 3

Another table (No. 38) is of interest, as showing the average rates from Chicago to New York by lakes, canal, and river. These in their quinquennial periods are given for the season as follows:—

In Cents per Bushel of 60 *lbs.*

1857–61.	1876–80.	1893–97.
22·15	10·47	4·92

In Shillings and Pence per Quarter of 480 *lbs.*

1857–61.	1876–80.	1893–97.

This latter mode is the cheapest by which grain can be carried to the eastern seaboard from the American prairies, and, as will be seen from the foregoing, it can now be done at a cost of 7s. 6d. per ton. The ocean freight has to be added before the grain can be delivered free on the quay at Liverpool. In December 1900 the rate from New York to Liverpool was 2½d. per bushel, or 7s. 10d. per ton, a low rate, it is true, in comparison with that which prevailed in former years, but yet sufficiently high, it was claimed, to leave a profit on a modern steamship; indeed, there have frequently been times when the rate was as low as 1d. per bushel, or 3s. 1d. per ton; and occasionally, in periods of great trade depression, wheat is carried from New York to Liverpool as ballast, actually being paid for by the shipowner. Another route which is also worked more cheaply than formerly is that by river, from the centre of the winter wheat belt, say at St Louis, to New Orleans, and thence by steamer to Liverpool. The river rate is now down below five cents per bushel, or 7s. per ton, 2240 lb. In Table No. 71 the cost of transportation is compared year by year with the export price of the two leading cereals in the States, and as we have not yet shown the annual average rates for the years severally, we reproduce the whole of this tabular statement:—

Wheat and Corn—Export Prices and Transportation Rates Compared.

Year.	Wheat. Export price per bushel.	Wheat. Rate, Chicago to New York by lake and canal, per bushel.	Wheat. Number of bushels carried for price of one bushel.	Corn. Export price per bushel.	Corn. Rate, Chicago to New York by lake and canal, per bushel.	Corn. Number of bushels carried for price of one bushel.

So much improved is the American farmer's position to-day as compared with what it was about the year 1870, that the transport companies in 1901 carried 17¼ bushels of his grain to the seaboard in exchange for the value of one bushel, whereas in 1867 he had to give up one bushel in every six in return for the service. As regards the British farmer, it does not appear as if he had improved his position at all; for, in the first place, he has to send his wheat to greater distances, owing to the collapse of so many country millers or their removal to the seaboard, while railway rates have fallen only to a very small extent; in the second place, the farmer's wheat is worth only half of what it was formerly; so in round numbers, it may be said that the British farmer has to give up one bushel in nine to the railway company for the purpose of transportation, whereas in the 'seventies he gave up one in eighteen only. Enough has been said to prove that the advantage of position claimed for the British farmer by Caird was somewhat illusory. Speaking broadly, the Kansas or Minnesota farmer's wheat does not have to pay (1902) for carriage to Liverpool more than 2s. 6d. to 7s. 6d. per ton in excess of the rate paid by a Yorkshire farmer; this, it will be admitted, does not go very far towards enabling the latter to pay rent, tithes, and rates and taxes, such as obtain in England and in nearly all old countries.

The subject of the rates of ocean carriage at different periods requires consideration if a proper understanding of the working of the foreign grain trade is to be obtained. Somewhat contrary to general expectations, it will be found that only a very small proportion of the decline in the price of wheat since 1880 is due to cheapened transport rates; for while the mileage rate has been falling, the length of haulage has been extending, until in 1900 the principal wheat fields of America were 2000 miles farther from the eastern seaboard than was the case in 1870, and consequently, notwithstanding the fall in the mileage rate of 50 to 75 per cent., it still cost the United Kingdom nearly as much to have its quota of foreign wheat fetched from abroad as it did then. The exact difference in the cost of the operation is shown in the following tabular statement, both the cost in the aggregate on a year's imports and the cost per quarter :—

Quantity of Wheat and Wheaten Flour (*as wheat*) *imported into the United Kingdom from various sources during the calendar year* 1900, *together with the average rate of freight.*

1900.

Countries of Origin.	Quantities. Qrs. 480 ℔	Ocean Freight to United Kingdom. Per 480 ℔.	Total Cost of Ocean Carriage.

Comparing the foregoing with a similar statement for the year 1872, the most remote year for which similar facts are available, it will be found that the actual total cost per quarter for ocean carriage has not much decreased.

Quantity of Wheat and Wheaten Flour (*as wheat*) *imported into the United Kingdom from various sources during the calendar year* 1872, *together with the average rate of freight.*

1872.

N.B.—There was a trifling quantity of Californian and Australian wheat imported in the period in question, but the Board of Trade records do not distinguish the quantities, therefore they cannot be given. The freight in that year from those countries averaged about 13s. per quarter.

The exact difference between the average freight for the years 1872 and 1900, it will be seen, amounts to about 2s. 11d. per quarter (480 ℔), a mere trifle in comparison with the actual fall in the price of wheat during the same years.

The following data bearing upon the subject, for selected periods, are partly taken from the *Corn Trade Year-Book* of 1896 :—

Year.	United Kingdom Annual Imports. Wheat and Flour. Qrs.	Ocean Freight to United Kingdom. Per qr.	Aggregate Cost of Carriage.
		s. d.	£
1872 .	9,469,000	6 5	3,040,000
1882 .	14,850,000	7 4	5,420,000
1894 .	16,229,000	3 9	3,041,000
1895 .	25,197,000	3 0	3,825,000
1896 .	23,431,000	2 9	3,258,000
1900 .	23,196,000	3 6	4,036,000

In passing, it may be pointed out that for a period of four years, from 1871 to 1874, the price of wheat averaged 56s. per quarter (or 7s. per bushel), with the charge for ocean carriage at 6s. 5d. per quarter, whereas in 1901 we had wheat at 28s. (or 3s. 6d. per bushel), and the

charge for ocean carriage at 3s. 6d. per quarter; the ocean transport companies carried eight bushels of wheat across the seas in 1901 for the value of one bushel, or exactly at the same ratio as in 1872. The contrast between the case of railway freight and ocean freight is striking, but is to be explained by the greater length of the present ocean voyage, which now extends to 10,000 miles in the case of Europe's importation of white wheat from the Pacific Coast of the United States and Australia, in contrast with the short voyage from the Black Sea or across the English Channel or German Ocean. It is largely due to the overlooking of this phase of the question that an American statistician has fallen into the error of stating that about 16s. per quarter of the fall in the price of wheat, which happened between 1880 and 1894, is attributable to the lessened cost of transport, he having apparently drawn his deduction from the narrow premises of the American railway and ocean freights.

It thus appears to be a fact that, whatever the cause of the decline in the price of wheat may be, it is not due solely to the fall in the rate of rail or ocean freights. Incidental charges, it is true, are lower than they were in 1870; handling charges, brokers' commissions, and insurance premiums have been in many instances reduced in recent years. Port dues and charges have occasionally been lowered by 1s. to 2s. per ton on each side of the Atlantic; commissions have been reduced by 1 per cent., or perhaps by a little more; insurance premiums are a trifle lower; but all these economies when combined will only amount to about 2s. per quarter. Now if we add together all these savings in the rate of rail and ocean freights and incidental expenses, we arrive at an aggregate economy of 8s. per quarter, or not one-third of the actual difference between the average price of wheat in 1872 and 1900. To what the remaining difference was due it is difficult to say with certitude; there are some who argue that the tendency of prices to fall is inherent, and that the constant whittling away of intermediaries' profits is sufficient explanation, while the bi-metallists maintain that the phenomenon is clearly to be traced to the action of the German Government in demonetizing silver in 1872.

Wheat Prices for 246 Years.

The following figures show the fluctuations from year to year, for 246 years, of English wheat, chiefly according to a record published by Mr T. Smith, Melford, the period covered being from 1656 to 1900:—

Price per Quarter.

	s.	d.		s.	d.		s.	d.		s.	d.		s	d.

The World's Grain Trade.

In the following statistical account of the world's grain trade, the principal details of each country's share are shown over a period of ten years or more. The accompanying diagram shows the world's crop, imports and exports, of the season 1898–99. For the chief countries, such as the United Kingdom and the United States, data for longer periods have been set down. The order in which the information is given is, as a rule, according to the importance of the country's contribution to the international trade, the United States claiming attention first of all, as it is *facile princeps* as a producer of foodstuffs.

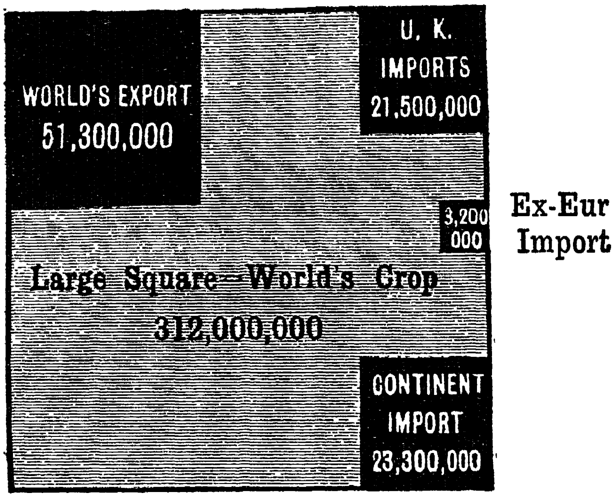

Diagram showing the World's Crop: Imports and Exports, Season 1898–99.
(The discrepancy between Exports and Imports is chiefly due to variations in quantities afloat.)
(*From a drawing by Mr Ernest Procter.*)

United States of America (population, 76,303,387: census 1900).—The record of America's development in this department of human industry is one of triumphant success. Every twenty-five years she doubles the size of her crops, partly owing to the rapid increase of population, but also largely due to improved methods of cultivation; the extent to which the latter statement is correct will be seen from the following figures:—

Per Capita Production of America during two Quinquenniums.

Years.	Wheat.	Maize.	Oats.	Barley.	Rye.
	Bushels.	Bushels.	Bushels.	Bushels.	Bushels.
1870–1874 .	6·3	24·4	6·2	0·7	0·4
1896–1900 .	7·2	27·2	9·9	0·8	0·3

The consumption per capita of wheat in the United States averages about $4\frac{2}{3}$ bushels as compared with about 6 bushels in the United Kingdom and 8 bushels in France. Of late years the discrepancy between the American and European rate has tended to become greater, and it is often doubted if the American domestic consumption now exceeds $4\frac{1}{2}$ bushels. The consumption of maize for all purposes per head of the population averages 25 bushels, and of oats $9\frac{1}{2}$ bushels.

While it will be seen that America raises enormous crops of grain, yet the rate of yield per acre is relatively very small. Of late years there has been a slight improvement in this respect, but still the average weight of wheat obtained from an American acre is only about one-half of that taken off an English, Scottish, or German area of equal size. The average yield between 1896 and 1900 was in the United States as follows:—

Wheat.	Maize.	Oats.	Rye.	Barley.
Bushels.	Bushels.	Bushels.	Bushels.	Bushels.
13·4	25·6	28 2	15·1	24·3

Production.

1899	66,300,000	2,910,020	8,953,000	96,500,000	252,000,000	5,701,000
1900	63,000,000	2,900,000	7,060,000	98,000,000	255,000,000	5,200,000

N.B.—The wheat crops of certain years were under-estimated by the Department, as indicated by subsequent distribution. They were estimated by the *Corn Trade News* to be as follows:—1900, 74,000,000 qrs.; 1899, 72,000,000 qrs.; 1898, 87,000,000 qrs.; 1897, 74,000,000 qrs.; 1896, 59,000,000 qrs.; 1895, 61,000,000 qrs.; 1894, 66,000,000 qrs.; 1893, 60,000,000 qrs.; 1892, 72,000,000 qrs.; 1891, 86,000,000 qrs.

Note.—In the reduction of the American Winchester bushel we reckon that 33 such bushels are the equivalent of 32 imperial bushels.

Wheat Crops—Acreage and Yield.

The following shows Department of Agriculture estimates of wheat production in 1900 for winter and spring wheat crops:—

States and Territories.	1900. Acreage.	1900. Bushels.
Ohio	1,420,646	8,523,876
Michigan . . .	1,219,969	9,271,764
Indiana . . .	1,209,755	6,411,702
Illinois	1,383,236	17,982,068

1889	16,331	2	1,421,051	2,788	300	..
1890	19,632	24,699	1,416,568	2,679	203	..
1891	68,246	17,592	634,841	1,211	264	4,312
1892	199,480	19	260,662	2,111	181	400
1893	138,098	1,063	158,115	2,211	275	266
1894	174,598	1,595	203,536	21,358	673	588
1895	241,142	36	153,173	19,262	1,830	1,526
1896	184,101	12	118,785	9,056	691	1,435
1897	191,700	9	158,900	5,800	785	1,575
1898	248,000	3,992	15,100	1,100	412	1,920

From the foregoing it will be observed that the States have never been importers of cereals excepting on a trifling scale, the only exception being in the case of barley, which during the 'eighties was freely imported from Canada, a trade which was cut short in the year 1891 by the imposition of prohibitive duties.

DISTRIBUTION OF WHEAT.

The following table exhibits the production of wheat, quantities required for food, seed, and exports between 1880 and 1899, on the authority of the Department of Agriculture crop returns, compiled by Mr C. B. Murray:—

Year.	Production. Bushels.	For Food. Bushels.	For Seed. Bushels.	Exportation. Bushels.	Total Distribution. Bushels.
1880	498,549,868	242,086,655	56,563,530	186,321,514	484,971 699
1881	383,280,099	243,000,000	55,215,573	121,892,389	420,107,962
1882	504,185,470	250,000,000	52,770,312	147,811,316	450,581,628
1883	421,086,160	256,000,000	54,683,389	111,534,182	422,217,571
1884	512,765,000	261,000,000	55,266,239	132,570,367	448,836,606
1885	357,112,000	267,000,000	51,474,906	94,565,794	413,040,700

The chief customer for the agricultural surplus of America is the United Kingdom, where more than half of her total exports are disposed of. The principal ports of export in the Union are New York, Baltimore, Philadelphia, New Orleans, Boston, Galveston, San Francisco, Williamette, and Puget Sound—named in the order of their importance.

Russia (population in Europe, 106,159,141; in Asia, 23,051,972: census 1897).—The Russian empire comes immediately after America as a grower of foodstuffs. As will be seen, the production of cereals (chiefly rye and oats) amounts roundly to 300,000,000 quarters.

[a] Returns for 50 governments. [b] Returns for 60 governments.
[c] Returns for 66 governments. [d] Returns for 69 governments.
[e] Returns for 71 governments.

In Russia the average yield per acre is, of winter wheat, 12·5 bushels; of spring wheat, 8 bushels; rye, 11 bushels; barley, 13 bushels; oats, 15 bushels; maize, 14 bushels.

The proportions of each sort of wheat raised in the different divisions of the empire are as follows, taking the official figures of the year 1899 as an instance:—

	Winter Wheat.	Spring Wheat.	Total.
	Qrs.	Qrs.	Qrs.
European Russia, 50 governments	12,300,000	26,960,000	39,260,000
Poland, 10 governments	2,600,000	25,000	2,625,000
Caucasia, 4 governments	5,340,000	1,800,000	7,140,000
Siberia, 4 governments	16,000	5,650,000	5,666,000
Central Asia, 4 governments	15,000	1,846,000	1,861,000
Total, 72 governments	20,271,000	36,281,000	56,552,000

During the eight years ending 1899 Russia has raised on an average 52,500,000 qrs. of wheat, and exported 13,000,000 qrs., leaving 39,500,000 qrs. for home consumption. Besides the cereal crops enumerated in the tabular statement, Russia annually produces four to five million qrs. of millet, three million qrs. of pease, and one million qrs. of spelt. In addition to the exports shown in the tabular statement, there were exported in the year 1899 556,000 cwt. of buckwheat, 271,000 cwt. of millet, 1,921,000 cwt. of pease, 1,853,357 cwt. of rye flour, and 7,292,570 cwt. of bran of all kinds. There are also certain quantities of beans and lentils grown and exported; in 1899 the quantity exported was 1,464,000. The consumption per head of wheat amounts to about 2½ bushels for the whole empire; of rye to 2·8 bushels per head for European Russia, and for the whole empire to a little over 5 bushels. The rye crop is almost entirely sown in the autumn, as is also half the wheat, but barley, oats, and maize are all spring-sown.

The chief shipping ports are Odessa, Nicolaieff, Taganrog, Rostoff, Novorossiysk for wheat, rye, and barley; but Libau, St Petersburg, Revel, and Riga ship the bulk of the oats. Odessa, Poti, and Novorossiysk are the chief shippers of maize. The chief customers for Russia's wheat exports are Germany, Italy, Belgium, Holland, France, Switzerland, and Spain. Great Britain occasionally takes considerable quantities when American wheat is relatively dear. Great Britain, Germany, and Holland are the principal buyers of Russian barley. Germany takes almost half the rye exports, and Great Britain half the oats and maize.

The effectiveness of Russia as a shipper is largely dependent upon prices, much more so than would seem to be the case with America, the explanation being, it is believed, that when prices are low only that portion of the empire immediately contiguous to the littoral remains operative as a shipper, for railway freights are not so elastic in Russia as they are in America.

EXPORTS (EXCLUSIVE OF FINNISH).

[a] From "Statistical Abstract for the Principal and other Foreign Countries."
[b] From the *Journal of Industry and Commerce of St Petersburg.*
[c] Cereal year, commercial return.

IMPORTS.

As might be expected, the imports of agricultural products are very small. In recent years they have been so insignificant that the returns have not been issued through the ordinary channels. Prior to the year 1886 certain quantities of wheat and spelt were imported, the official returns in quarters for the years named being, 160,000 in 1880, 150,000 in 1881, 452,000 in 1882, 306,000 in 1883, 302,000 in 1884, 1,394,000 in 1885, and 604,000 in 1886.

Rumania (population, 5,912,520; census 1899).—This little kingdom has always been a successful raiser of foodstuffs, for as far back as 1862 the records show that substantial crops of wheat, maize, and barley were grown, and indeed the yields of cereals in the year 1868 were as important as they are to-day. Unfortunately the agricultural data between the years 1877 and 1885 are missing, or otherwise we should have a forty years' record, or one twice as old as Great Britain possesses.

[a] Unofficial.

The average yield per acre of wheat is 14 bushels, barley $16\frac{1}{2}$ bushels, oats 19 bushels, rye 15 bushels, maize 17 bushels, and millet 12 bushels. The average rate of consumption per capita in Rumania comprises 5 bushels of wheat and 7 bushels of maize. The present area under wheat is 3,855,000 acres, under maize 5,000,000 acres, under barley 1,500,000 acres, under oats 700,000 acres, under rye 500,000.

[a] Including malt from and after 1887.

One often meets with higher estimates of Rumania's exports, but that is due to the fact that considerable quantities of Bulgarian grain coming down the Danube get mixed up with the quantities actually grown in Rumania. The chief ports of export are Braila and Galatz on the Danube in the summer, and Sulina at the mouth of the Danube and Constanza on the Black Sea in the winter. The chief customers for Rumania's wheat are Belgium, Germany, Holland, and Italy, while the United Kingdom takes the principal share of the maize.

Bulgaria (population, 3,733,189 ; census 1900).—Agricultural statistics are not so readily obtainable from this principality as from the neighbouring kingdom of Rumania, but the *Corn Trade News* has collected returns from various authorities which are believed to be trustworthy. These are given below, in which are also comprised the figures for Eastern Rumelia.

Bulgaria and Eastern Rumelia : Production.

(*From the Corn Trade Year-Book and Commercial Estimates.*)

Year.	Wheat.	Rye.	Barley.	Oats.	Maize.
	Qrs. 480.	Qrs. 480.	Qrs. 400.	Qrs. 304.	Qrs. 480.
1890	2,500,000	..	..	.	..
1891	3,700,000	1,298,000	1,463,000	840,000	..
1892	3,600,000	850,000	1,688,000	900,000	..
1893	3,600,000	700,000	2,000,000	600,000	..
1894	3,100,000	800,000	1,500,000	800,000	..
1895	3,800,000	900,000	2,000,000	800,000	..
1896	5,000,000	600,000	2,500,000	700,000	2,800,000
1897	3,400,000	1,200,000	1,400,000	500,000	3,500,000
1898	4,700,000	800,000	1,600,000	1,100,000	4,000,000
1899	2,900,000	600,000	1,250,000	620,000	2,400,000
1900	4,000,000	900,000	1,250,000	500,000	1,500,000
1901	4,100,000	1.000,000	1,600,000	800,000	3,700,000

Eastern Rumelia is credited with raising 700,000 quarters of soft wheat and 80,000 quarters of hard wheat, which are included in above. The official figures for Bulgaria alone, appearing in the *Résultats des Ensemencements et de Récolte dans la Principauté de Bulgarie,* are as follows :—

Bulgaria : Acreage under Crops in Statute Acres.

Year.	Wheat.	Rye.	Barley.	Oats.	Maize.
1897-98	1,932,753	347,000	498,900	346,000	1,221,000
1898-99	2,039,444	365,000	528,000	337,000	1,104,000

Bulgaria : Yield of Crops in Imperial Bushels.

Year.	Wheat.	Rye.	Barley.	Oats.	Maize.
1897-98	33,983,000	5,072,000	11,712,000	8,746,000	35,224,000
1898-99	21,623,000	4,343,000	6,382,000	4,731,000	19,092,000

The yield per acre for the two years averaged nearly 14 bushels of wheat, 13 bushels of rye, $17\frac{1}{2}$ bushels of barley, 20 bushels of oats, and over 23 bushels of maize.

The consumption per capita of wheat would seem to be about 5 bushels.

Bulgaria : Exports.

(*From " Statistique du Commerce de Bulgarie."*)

1894	1,292,703	135,100	126,253	31,754	982,072	35,230
1895	1,772,500	203,259	137,253	2,431	222,873	53,970
1896	2,777,700	213,738	127,342	6,240	495,713	55,923
1897	1,293,900	77,115	96,771	25,833	358,330	27,855
1898	856,423	109,440	269,072	32,082	609,501	56,280
1899	554,200	30,000	56,100	40,500	722,000	51,500
1900	585,500	112,100	220,000	9,400	186,000	70,900

The chief ports from which direct shipments are made are Varna and Baltchick in Northern Bulgaria, but a great deal of stuff is sent down the Danube and is included in the Rumanian quantities. Bourgas is the port of Southern Bulgaria or Eastern Rumelia.

The imports of agricultural products are trifling.

Servia (population, 2,493,770 ; census 1900).—Agricultural returns of this kingdom are issued only at long intervals. In 1893, 783,162 acres were credited with producing 8,700,000 bushels of wheat ; 227,540 acres with 2,412,000 bushels of barley ; 261,735 acres with 2,672,000 bushels of oats ; 147,755 acres with 1,226,000 bushels of rye ; and 1,313,562 acres with 16,882,000 bushels of maize ; the yields per acre being 11 bushels of wheat, $10\frac{1}{2}$ bushels of barley, 10 bushels of oats, $8\frac{1}{4}$ bushels of rye, and $12\frac{3}{4}$ bushels of maize. The total production of several years, as given by various authorities, is shown below :—

Production.

(*British Consular data, excepting* 1893, *which is official.*)

Year.	Wheat.	Rye.	Barley.	Oats.	Maize.	Potatoes.
	Qrs. 480.	Qrs. 480.	Qrs. 400.	Qrs. 304.	Qrs. 480.	Tons, 2240
1890	1,275,200	161,600	474,100	515,300	2,986,200	..
1891	1,331,600	170,800	491,000	525,000	3,157,100	..

1893	1,081,500	148,400	297,000	363,000	2,110,000	21,300
1894	1,284,400	190,900	512,900	551,800	3,344,300	..
1895	1,157,800	194,200	455,500	579,300	3,528,800	..
1896	1,300,300	160,900	508,600	624,400	3,606,000	..
1897	1,674,100	222,400	469,000	1,032,200	3,975,200	..
1898	1,314,200	212,400	540,400	646,100	3,743,800	..
1899	1,482,000	197,800	474,300	628,400	3,840,500	..
1900	955,285	102,657	148,234	273,559	..	..
1901	1,100,000	..	..	..	..	..

The quantities exported are not very important ; such as they are they will be found in the following tabular statement. The consumption per capita in the year 1893 was estimated as follows :—Wheat $5\frac{3}{4}$ bushels, and maize $6\frac{1}{3}$ bushels, but in subsequent years maize appears to have amounted to 11 bushels and over.

Exports.

1900	455,000	21,000	104,000	45,000	285,000	1000

Austria-Hungary is the chief customer for Servia's exports, but the suspension of the "Mahlverkehr" has seriously curtailed it. The imports, as might be expected, are, as a rule, insignificant ; the only year when they were worth reporting was in 1898, when 105,000 quarters of maize were received from neighbouring countries.

Turkey in Europe.—No official returns of production or exportation are published at Constantinople, but in

commercial circles it is known that the country grows just about what it needs for its own consumption. Constantinople imports weekly about 4000 quarters of wheat and 10,000 bags of Russian flour, but other parts of the empire export small quantities of wheat, and occasionally substantial shipments of maize, barley, and oats are made at Salonica. The crops of the province of Salonica for the year 1900 were as follows:—Wheat acreage 861,000, yield 800,000 qrs.; barley acreage 343,000, crop 460,000 qrs.; oats acreage 104,300, crop 209,000 qrs.; rye acreage 172,000, crop 117,000 qrs. The port of Dedeagatch also occasionally exports certain quantities of cereals.

Austria-Hungary (population—Austria, 26,107,304; Hungary, 19,203,531: census 1900).—The dual monarchy now plays a far less important part in the international grain trade than formerly, as will be seen from the subjoined summary of the exports and imports of the chief cereals. It is not because Hungarian wheat has deteriorated in quality, for it still holds a high place in the estimation of millers everywhere; but it would seem that it cannot compete in price with the product of the prairies of North and South America. The ordinary area under the premier cereal in Hungary is 7,500,000 acres, in Austria 2,500,000 acres, and in Croatia-Slavonia 600,000 acres; the yield per acre in Hungary averaging 17 bushels, in Austria 16, and in Croatia-Slavonia 15 bushels. The annual consumption of wheaten bread stuffs in the empire amounts roundly to 24,000,000 qrs., or 4½ bushels per caput. The chief customers for the small quantities of wheat now exported are Germany, Switzerland, and Italy; but the United Kingdom is the best customer for flour, followed at a great interval by Germany and France. The bulk of the barley exports goes to Germany. The chief ports of shipment are Fiume for Hungarian produce, and Trieste for Austrian. The imports into Austria-Hungary chiefly come from Russia, Rumania, and Servia, mainly by way of the Danube. It should be noted that for many years a large trade was carried on in manufacturing imported wheat in bond into flour, and exporting it to the United Kingdom, Germany, and other countries; but at the end of June 1900 the trade was abolished at the instance of the Austrian millers and the Hungarian agriculturists. The annual exports from bond ranged between 700,000 and 1,000,000 sacks (280 lb).

1897	129,400	400	1,974,800	11,000	86,500	82,500
1898	13,300	1,800	1,829,500	66,700	13,900	27,300
1899	3,293	2,921	2,278,386	455,532	15,947	864,500
1900	37,500	1,700	1,651,900	241,100	9,800	369,400
1901	97,600	1,100	1,787,900	27,100	59,700	664,500

N.B.—In addition to the above specified exports, the dual empire sends away annually about 400,000 quarters of beans, and formerly sent away 700,000 to 1,000,000 sacks of flour manufactured in bond. Since the year 1897, when there was a crop failure throughout the empire, the tide has turned, and large quantities of wheat, rye, and maize are being imported.

IMPORTS.

Canada (population officially estimated in 1900 at 5,522,500).—The progress of agriculture in the Dominion seems slow in comparison with that of the United States, for there are many single states in the Union which alone

produce a far greater crop than all the provinces of the Dominion combined. The climate and soil are not to be blamed for this state of things, for in many parts of Canada they are magnificent; the real cause being the lack of immigrants of the class which will endure the drudgery of raising crops of wheat and maize in a new and sparsely settled country. Such agricultural progress as is being made seems solid and safe, the cultivation is more careful, thorough, and scientific, with the result that the average product of an acre of land in Canada is at least 25 per cent. higher than in the States. The chief agricultural districts are Ontario and Manitoba. In the former the average yield of winter wheat is 20 bushels; of spring wheat 16 bushels, barley 26 bushels, oats 35 bushels. In Manitoba the average yield is 18 bushels of spring wheat, 30 bushels of barley, and 35 bushels of oats. The average per caput consumption of wheat in the Dominion on the data for 1897–1900 apparently reached 7 bushels, or a mean between the French and English rate.

Crop of 1901.

	Ontario.	Manitoba.	North-West.	Nova Scotia.
	Bushels	Bushels.	Bushels.	Bushels.
Crop.	21,500,000	50,500,000	12,500,000	180,000

The harvest of spring wheat in Canada in 1900 was very deficient, owing to a severe spring drought. The crop of wheat raised in 1901 creates a record.

The following tabular statement gives the production during a number of years :—

Production.

(*From the Statistical Year-Book.*)

Year.	Wheat.	Rye.	Barley.	Oats.	Pease.
	Qrs. 8 bush.	Qrs. 8 bush.	Qrs. 8 bush.	Qrs. 8 bush.	Qrs. 8 bush.

1898	7,986,900	334,200	2,206,000	14,387,600	1,690,200
1899	7,070,000	260,000	2,600,000	14,800,000	1,890,000
1900	4,800,000	298,000	2,510,000	13,100,000	1,710,000
1901	10,500,000	400,000	3,000,000	14,600,000	..

From 1885 to 1897 inclusive the production of provinces of Ontario and Manitoba only is given.

For a long period Canada has been a shipper of grain to the mother country, the product of the wheat fields of the North-West being held in high estimation by millers. Pease also are shipped in large quantities. The following tabular statement shows the progress of trade between 1885 and 1899 :—

Exportation (Domestic Produce).

(*From Statistical Year-Book.*)

Year ended June 30.	Wheat.	Rye.	Barley.	Oats.	Pease.	Wheat Flour.
	Qrs. 8 bush.	Qrs. 8 bush.	Qrs. 8 bush.	Qrs. 8 bush.	Qrs. 8 bush.	Sacks, 280 ℔.

1900	3,500	35,000	..	60,000	..	.

Corn imported free for ensilage not included in 1890–96.

Note.—Flour computed at $4\frac{1}{2}$ bushels of grain to the barrel 1873 to 1897, and 4 bushels and 35 ℔ in 1898.

British India (including the native states: population, 295,252,700; census 1901).—This great dependency, with an area less than half the size of the United States, raises a wheat crop of about 30,000,000 qrs.—of which 10 per cent. is available for exportation to Europe, the remaining 27,000,000 qrs. being consumed, it is estimated, by the 60,000,000 wheat-eating population, at the rate of about $3\frac{1}{2}$ bushels per head. Once in every five years since 1885 the crop has proved a failure, more or less complete. The Central Provinces and Sind usually suffer most severely in this respect. The exportation of wheat on a wholesale scale commenced in the year 1873, and by the year 1877 the shipments had assumed material proportions, being returned as 1,500,000 qrs. During the famine of 1878–79 they fell away again, but in the year 1881 they reached the big total of 4,600,000 qrs., and were the means of breaking the level of prices in Europe to the extent of something like 10s. per quarter between the years 1882 and 1884, the old minimum price of 45s. giving place to one of 35s. In 1891 India's exports reached the high-water mark, for not less than 7,000,000 qrs. were shipped to Europe to help fill the gap caused by crop failures in France and Russia. Since that time India has played a less important part in the international grain trade; but once more, namely in 1898, the year of the Leiter corner and of France's big requirements, India came opportunely to the rescue and shipped 4,500,000 qrs., the bulk of it in a surprisingly short space of time.

The following shows the normal area, product, and yield per acre of each of the chief provinces :—

	Average five years 1895–99.		Yield per acre in bushels 60 ℔.
	Area in acres.	Product in tons.	
Punjab	7,540,000	2,163,908	10·7
North-West Prov. and Oudh	4,332,252	1,418,972	12·2
Bengal	1,513,500	476,400	11·7
Central Province . . .	2,846,187	461,492	6·0
Bombay	2,175,523	575,521	9·8
Sind	503,160	148,311	11·0
Berar	669,864	52,735	2·9
Nizam's Territory . .	1,491,683	93,829	2·3
Rajputana	1,400,722	331,775	8·8
Central India . . .	1,853,789	316,517	6·3
Mysore	4,556	353	2·8
Average	24,331,236	6,039,813	9·3

Before the failure of 1899–1900 there had been a constant growth of the area under wheat in the Punjab, the average acreage of the previous five years being 7,540,000, as compared with 7,100,000 acres, the area of the decade 1890–99, and it is probable that a further growth may occur in these parts. On the other hand, it would seem as if wheat-growing were doomed in the Central Provinces, for failure after failure has happened, until we find the acreage for 1898 and 1899 only averaged 2,000,000 in comparison with a mean of 2,800,000 for the five years 1895–99, and 3,400,000 the mean of the ten years 1890–99. In Central India the situation is as bad, for the acreage of 1898 and 1899 only averaged about 1,000,000 compared with 1,850,000, the mean of the preceding five years. The most fertile land is to be found in the north-west parts of Bengal, Punjab, Sind, and Bombay, but the average yield even in these tracts only amounts to about 11 bushels per acre.

The port of Kurrachee (Karachi) is now far and away the most important wheat port of India, having wrested the palm from Bombay, which about 1880 wrested it from Calcutta, where the trade originated. The produce of the fields of Bengal, and largely of the North-West Provinces and Oudh, reaches the port of Calcutta for shipment by sea. The port of Bombay gets all the produce of the Presidency of Bombay, the Central Provinces, Berar, Rajputana, and Central India, with a share of that from the North-West Provinces and Oudh, and the Punjab. Kurrachee gets the produce of Sind and the bulk of the Punjab surplus. In the record season of 1891–92 the three ports shipped the quantities placed against their names—Bombay, 3,380,000 qrs.; Kurrachee, 2,437,000 qrs; Calcutta, 1,184,000 qrs. In addition to wheat, India ships about 30,000,000 cwt. of rice or paddy per annum, 15,000,000 cwt. of oil-seeds, and 2,000,000 cwt. of pulse, &c.

The sowing season in the Punjab may extend from September to late in January; in the North-West Provinces, Oudh, Bengal, Central Provinces, Berar, and Rajputana from September to December; in the Nizam's Territory from September to November; and in Bombay and Sind from October to December. The harvest usually takes place in the month of March, excepting in the Punjab and parts of the North-West, where it falls six or eight weeks later.

PRODUCTION (WHEAT).

(*From the Reports of the Revenue and Agriculture Department of the Government of India.*)

(Harvested March/April.)

Year.	Qrs 480.	Year.	Qrs 480.	Year.	Qrs. 480.
1885	35,900,000	1890	28,778,000	1895[d]	29,516,000
1886	36,100,000	1891[a]	32,317,000	1896	25,897,000
1887	29,800,000	1892	26,014,000	1897	22,992,400
1888	33,100,000	1893[b]	33,807,000	1898	31,424,000
1889	29,901,000	1894[c]	31,823,000	1899	29,793,000
				1900	22,983,000

[a] Believed to have been under-estimated by 2,000,000 qrs.
[b] Believed to have been over-estimated by 4,000,000 qrs.
[c] Believed to have been over-estimated by 3,000,000 qrs.
[d] Subsequently amended to 32,070,000 qrs.

Of rice India produces about 500,000,000 cwt., and of oil-seeds about 40,000,000 cwt.

In the following tabular statement will be found the annual exports of India of grain by sea between 1885 and 1901, the exports by land being inconsiderable :—

EXPORTS BY SEA.

1900–1901	12,000	31,342,000	925,551	10,997,000	199,500

The export of wheat during the season 1900–1 was practically nil.

As would be expected, India imports only trifling quantities of agricultural products; even during famines the quantities do not amount to anything material. In the year 1877, 101,000 qrs of wheat was entered, and in 1896, 140,000 qrs. of the same cereal was imported, some of which was re-exported in the succeeding season.

Australian Commonwealth, and *New Zealand* (population 4,513,399, estimated 1900).—That wheat raising should be successfully carried on in a country where the average return is so low as in the two chief states, South Australia and Victoria, where the average value per acre is valued at from 8s. to 13s. 6d., compared with 40s. in America and £6 or £7 in England (the straw being included in the latter case), is wonderful. A total area under wheat of 5,884,116 in 1899 giving a total yield of 48,580,000 bushels or 6,070,000 qrs. is from a British standpoint a very poor return for labour and capital, although the season was a highly satisfactory one. The average yield per acre works out at rather over 8 bushels per acre, ranging from under 5 bushels in South Australia to 32 bushels in New Zealand. The following shows the area, product, and average yield per acre for the year 1899, the crops being sown in June and reaped in November and December in the Australian Commonwealth, and about two months later in New Zealand.

	Acreage	Production (bushels).	Yield per acre (bushels)
New South Wales . .	1,426,166	13,604,166	9·5
Victoria	2,165,693	15,237,948	7·03
Queensland	52,527	641,314	12·2
South Australia . . .	1,821,137	8,453,135	4·6
West Australia . . .	84,516	987,329	11·6
Tasmania	64,328	1,101,303	17·1
New Zealand . . .	269,749	8,581,898	31·8
Total	5,884,116	48,607,093	8·3[a]

[a] Average.

The indicated per caput consumption of the whole of Australasia works out at about 6½ bushels for all purposes. The averages for 1890–99 were:—Wheat crop, 4,600,000 qrs.; exports, 1,550,000 qrs.; wheat and flour imports, 250,000 qrs.; net quantities consumed or seeded in the colonies 3,300,000 qrs., or 6½ bushels per head, of which one bushel is used for seeding, and the balance for human food.

Argentina (population, 4,794,149; census 1900).—This South American republic, with an area nine times that of the United Kingdom, in 1899 took second place in the international grain trade as a shipper of wheat. The wheat and linseed crops are mostly grown in the provinces of Santa Fé, Buenos Aires, Cordoba, and Entre Rios; the maize crop being raised chiefly in Buenos Aires, and moderately in Santa Fé. The wheat area now amounts to 9,000,000 acres, a growth of 3,000,000 since 1895. The area under maize is given as 2,500,000 acres, against 3,000,000 in 1895. The wheat exports commenced in 1871 with 9 tons; in 1900 they reached 8,862,300 quarters, besides 403,000 sacks of flour. Maize exports commenced in 1864 with 14 tons, and reached in 1896 a total of 7,214,000 quarters. The exportation of linseed has now reached an annual total of 200,000 tons. The area, production, and yield per acre of the chief provinces was officially estimated as follows for the year 1899:—

Wheat crop planted about June; reaped December.

PRODUCTION.

	Acres.	Bushels	Yield per Acre.
Santa Fé . .	3,991,000	45,897,000	11·5
Buenos Aires . .	1,849,000	29,581,000	16·0
Cordoba . . .	1,154,000	12,691,000	11·0
Entre Rios . .	580,000	6,612,000	11·4
Others . . .	173,000	1,903,000	11·0
	7,747 000	96,684,000	12·5

The average yield per acre for the whole country ranges from 18 bushels in a good year like 1893 to 7 bushels in a bad year like 1896, the highest yield now, as a rule, being obtained in the province of Buenos Aires off virgin soil. The average per caput consumption of wheat during the decade ending the 19th century was nearly 6 bushels for all purposes, of which about 1¼ bushel was used for seed.

The production of wheat and maize during the period 1887–1901, and of the minor crops for the year 1899, is given in the following tabular statement:—

PRODUCTION.

(From the Corn Trade Year-Book and other Sources.)

Year.	[a] Wheat.	Linseed.	[b] Maize.
	Qrs. 480.	Tons.	Qrs. 480.
1887	4,000,000	..	4,100,000
1888	3,800,000	...	3,200,000
1899	3,000,000	...	4,500,000
1890	4,100,000	...	5,500,000
1891	4,600,000	...	2,500,000
1892	6,900,000	...	4,500,000
1893	11,000,000	...	2,700,000
1894	7,500,000	...	2,000,000
1895	5,500,000	...	9,000,000
1896	3,100,000	...	10,000,000
1897	6,200,000	...	5,000,000
1898	13,600,000	200,000	7,000,000
1899	12,700,000	200,000	9,000,000
1900	9,000,000	250,000	7,000,000
1901	6,000,000		8,000,000

[a] Reaped in December. [b] Reaped in March.

The average yield per hectare of linseed is stated to be 660 kilos, of rye 790, of barley 860 kilos.

Previous to 1899 there were no statistics of the production of rye, barley, and linseed, but in that year the quantities raised were respectively 5000 qrs. (of 480 ℔), 30,000 qrs. (of 400 ℔), and 200,000 tons.

[a] Cereal year.

The imports of agricultural products are insignificant, but in the year 1897, owing to the crop failure, and for the sake of getting some new seed, a few cargoes of American and Russian grain were imported, amounting in all to 66,000 quarters.

The chief customers for Argentina's wheat are the United Kingdom, Belgium, France, and Germany; the last country getting its supply through Hamburg, Rotterdam, and Antwerp. Brazil takes annually about 300,000 qrs. of wheat, 250,000 sacks of flour, and 200,000 qrs. of maize. Uruguay and Paraguay also take certain quantities when their own crops are bad. A great deal is described in the official returns as shipped to Portugal, but this means simply that it is shipped to St Vincent for orders, as it is to Las Palmas and Falmouth. The chief wheat ports are Rosario, Buenos Aires, and Bahia Blanca. Maize is shipped chiefly from Buenos Aires and La Plata.

Uruguay (population, 930,680; census 1900).—In the early 'nineties it seemed as if this republic were going to join Argentina in supplying Europe with wheat, but the export proved to be a mere flash in the pan, and after raising 1,100,000 qrs. in 1894–95, the production fell off. In September 1900 at Montevideo there was issued an official estimate of the production, which gave it as 894,000 quarters grown on an acreage of 836,000, equalling a yield of a fraction over 8 bushels per acre—a great falling off since the previous estimates of 1893 and 1894, when the yields were 11 and 17 bushels respectively. Taken upon a ten years' average, the consumption per caput for all purposes appears to have been nearly 4½ bushels. The chief crop after wheat is maize, of which half a million to a million quarters are raised in good years, the yield per acre in a good season averaging 17 bushels; the total annual exports amounting to 300,000 or 400,000 quarters. The shipments are made from the port of Montevideo, the principal purchasers being the United Kingdom, Antwerp, and Brazil.

Paraguay (population, 635,571; census 1900).—No official statements for either acreage or production are available for this country. The trade is very small.

WHEAT IMPORTS.

1885, 6476 bushels; 1886, 77,794 bushels; 1887, 69,760 bushels

FLOUR IMPORTS.

1881, 1,290,344 ℔; 1882, 1,680,802 ℔; 1883, 2,177,016 ℔; 1884, 2,047,456 ℔; 1885, 1,908,419 ℔; 1886, 385,225 ℔; 1887, 1,338,862 ℔.

In addition, a small trade in maize and potatoes is carried on.

Chile (population, 3,110,000; census, November 1899).—This country, after being a steady exporter of a moderate quantity of wheat and barley for many years, seems as if it were being beaten out of the field by other growers. The wheat product formerly was about 2,000,000 qrs., and the annual exportation about 500,000 qrs.; but the production has now fallen off so seriously that importation of Californian and Australian wheat has commenced on a large scale. The indicated per caput consumption on a ten years' average was 5½ bushels for all purposes.

Wheat (Production) Harvested January-February.

(*From the Corn Trade Year-Book.*)

	Qrs. 480.		Qrs. 480.
1891	2,100,000	1897	1,600,000
1892	1,900,000	1898	1,500,000
1893	2,100,000	1899	1,400,000

1895	1,600,000	1901	1,000,000
1896	1,900,000		

There are no official estimates of the area or average yield issued, but there are complete returns of the exports and imports published regularly, as will be seen from the following:—

Exports.

(*From Estadistica Comercial de la Republica de Chile.*)

Year.	Wheat.	Barley.	Maize.	Flour of all kinds.
	Qrs. 8 bush.	Qrs. 8 bush.	Qrs. 480 lb.	Sacks, 280 lb.
1885	493,036	43,872	...	44,404
1886	560,808	52,921	...	54,498
1887	572,100	22,200	250	24,000
1888	427,258	133,523	200	24,908
1889	228,574	38,599	500	24,806
1890	133,032	33,891	100	17,103
1891	819,020	76,736	300	45,259
1892	670,689	73,485	1300	30,707
1893	855,429	148,967	...	17,229
1894	534,681	210,199	...	24,616
1895	361,468	309,501	...	30,407
1896	632,799	285,048	...	32,405
1897	332,500	103,985	250	42,040
1898	364,000	101,000	1000	47,800
1899	210,000	143,000	2000	53,000

The imports are only important in the case of flour and maize, and these only occasionally. The great port for wheat shipments is Talcahuano. Almost the entire exportation of wheat and barley comes to the United Kingdom.

Algeria (population, 4,824,000; census 1901).—The progress of agriculture in this part of North Africa, as well as in the neighbouring countries of Tunis and Tripoli, is kept in check by the twin evils, droughts and locusts. The following figures show the average yield per acre of wheat, barley, and oats:—

	Acreage.	Product.	Yield per Acre.
		Bushels.	Bushels.
Wheat	3,219,848	22,240,000	7
Barley	3,446,966	32,000,000	9¼
Oats	209,036	3,600,000	17¼

The general production between 1891 and 1900 was as follows:—

Year.	Wheat.	Barley.	Oats.	Maize.
	Qrs.	Qrs.	Qrs.	Qrs.
1891	3,270,000	5,009,000	360,000	46,000
1892	2,500,000	4,500,000	275,000	39,000
1893	2,510,000	3,950,000	305,000	40,000
1894	3,880,000	5,750,000	532,000	49,000
1895	3,246,000	4,630,000	533,000	60,000
1896	2,860,000	3,730,000	543,000	54,500
1897	2,470,000	3,004,000	415,000	35,000
1898	3,380,000	4,956,000	630,000	40,000
1899	2,780,000	4,000,000	450,000	40,000
1900	2,200,000	6,600,000	720,000	40,000
1901	2,900,000	4,000,000	470,000	...

The trade with Algeria in grain is of no consequence to any nation beside France. In the last two years for which official returns are obtainable we have as follows:—

	Importations.		Exportations.	
	1898.	1897.	1898.	1897.
	Quintals.	Quintals.	Quintals.	Quintals.
Cereals, grain and flour	968,575	722,067	1,558,209	2,108,411
Rice, its flour, and semolina	6,476,212	5,381,310	...	...
Bran	...	...	2,770,747	2,869,850

Tunis (population, 1,906,000; estimate 1889).—Of this country very few agricultural or trade statistics are published. The area under crops in 1898 and 1899 was believed to be as follows, in hectares:—

Year.	Wheat.	Rye.	Barley.	Maize.
1898	358,462	370,684	6933	19,738
1899	367,690	403,409	6480	6,285

For the year 1898 the following figures represent the imports and exports:—

	Wheat.	Barley.	Wheat Flour.
Imports: quintals	88,750	137,635	77,448
Exports: quintals	671,377	495,181	146

Tripoli (population, 800,000; estimate 1899).—This vilayet grows certain quantities of barley, and exports, chiefly to the United Kingdom, 20,000 qrs. and occasionally 50,000 qrs. annually. It also imports from Italy and France about 40,000 sacks of flour annually.

Egypt (population, 9,734,405; census 1897).—Notwithstanding the general prosperity of the Khedive's dominions under British protection, it cannot be said that agriculture is prospering. There are but few data obtainable as to the production, but the record of exports and imports is very complete, and these will be found annexed.

Production.

Turkey in Asia and *Syria.*—The production of cereals in this part of the Sultan's empire has shrunk into insignificance. Small quantities of barley, wheat, beans, and dari are occasionally shipped; but the only port which maintains any real importance is Smyrna, whençe a considerable quantity of excellent barley is shipped annually, mostly finding its way to the United Kingdom. In 1900 the exports amounted to 974,000 qrs. of barley, 58,000 qrs. of beans, 26,000 qrs. durra; or of all cereals, expressed in tons, to 196,756, or 110,000 tons in excess of 1899; the increase being due to the exceptionally fine barley crop. The United Kingdom received 188,626 tons, leaving 8130 tons only for all other countries.

Cyprus (population, 227,900; census 1899).—The agricultural and trade statistics are very complete and satisfactory. In the following tabular statements will be found details of exports and imports from 1890 to 1899:—

PRODUCTION.

(*From Board of Trade Returns.*)

Year.	Wheat.	Barley.	Oats.
	8 bush.	8 bush.	8 bush.

1899	269 000	305 000	33,800

EXPORTS.

(*From Statistical Abstract for the several Colonial and other Possessions of the United Kingdom.*)

Year.	Wheat.	Barley.	Oats.
	8 bush.	8 bush.	8 bush.
[a] 1890	64,600	115,200	5,800
[a] 1891	50,000	119,000	8,200
[b] 1892	17,500	41,900	9,400
[b] 1893	13,500	72,700	13,200
[b] 1894	50,600	56,800	14,100
[b] 1895	38,200	65,300	23,100
[b] 1896	16,200	55,200	14,300
[b] 1897	6,600	31,300	10,800
[b] 1898	26,250	97,100	9,700
[b] 1899	3,000	46,800	7,700

[a] Year ended 31st March. [b] Year ended 31st December.

The imports of wheat into Cyprus are unimportant, but a small amount of flour and a moderate quantity of rice are landed annually. In 1898, 16,800 cwt., and in 1899, 11,800 cwt. of rice were imported.

Malta (population, 181,648; estimated 1899).—The area under wheat in 1899 was 8308 acres, and under barley 2771 acres. The yield of wheat was 153,416 bushels, or 18 bushels per acre; and of barley 70,000 bushels, or 24 bushels per acre. The production in 1899 was 19,000 quarters of wheat and 8700 quarters of barley. The imports consist chiefly of flour from France and Italy, and certain quantities from the United Kingdom.

Persia (population estimated at 8,000,000).—This kingdom is credited with raising 2,000,000 quarters of wheat and barley, but the figures are untrustworthy. Occasionally the United Kingdom gets a few thousand quarters of wheat, and somewhat larger quantities of barley; but often enough the exportation of foodstuffs is prohibited. The ports from which they are shipped are Bushire, Lingah, Bander Abbási, Bahrein, Arab coast ports, and Mohammerah.

Japan (population, 46,540,744, including Formosa and the Pescadores; census, December 1898).—Agricultural and trade statistics are very complete for this kingdom, and go back for a number of years. The figures for the 1898 crops are as follows:—

	Acreage.	Production.	Yield. per Acre.
		Bushels.	Bushels.
Wheat .	1,140,740	20,742,164	18
Barley .	1,616,255	44,211,258	27
Rye . .	1,669,342	36,538,361	22

The production and exports and imports since 1890 are shown in the following three statements:—

PRODUCTION.

Year.	Wheat.	Rye.	Barley.	Beans and Pease.	Potatoes.	Rice.
	Qrs. 480.	Qrs. 480.	Qrs. 400.	Qrs. 8 bush.	Tons, 2240.	Cwt. 112 lb.
1890	1,503,000	1,768,000	3,354,000	..	..	106,733,000
1891	2,169,000	3,963,000	5,031,000	..	..	94,546,000
1892	1,883,000	3,755,000	4,221,000	..	149,100	102,619,000
1893	2,014,000	3,810,000	4,462,000	..	..	92,250,000
1894	2,429,000	4,467,00	5,223,000	2,200,000	183,900	102,446,000
1895	2,434,000	4,297,000	5,228,000	2,320,000	163,400	99,804,000
1896	2,175,600	3,629,000	4,808,000	1,859,000	162,900	89,337,000
1897	2,334,600	3,776,000	4,917,000	1,922,000	216,300	81,930,000
1898	2,592,000	4,567,000	5,526,000	..	..	116,102,000
1899	2,500.000	4.100,000	5,260,000	.	..	97,600,000

N.B.—The sweet potato crop is ten or fifteen times as big as the other potato crop.

EXPORTS.

1895	1,031	..	51,500	300,000	1,850,000
1896	10,700	..	113,900	435,800	2,200,000
1897	44,300	..	111,200	651,000	7,480,000
1898	13,300	..	184,500	666,800	13,850,000

The imports of oats and maize are unimportant.

On the average for the ten years ending 1898 the consumption of wheat for all purposes amounted to only 0·4 of a bushel—rice and sweet potatoes forming the chief food crops of Japan.

United Kingdom (population, 41,454,578; census 1901).—Regular official estimates of crop production in the United Kingdom were first made in 1884. The figures relating to the production of wheat between the years 1884 and 1900 inclusive are from the agricultural produce statistics of Great Britain, with additions from the returns of the registrar-general for Ireland. The statistics for years prior to 1884 are from a statement published by the late Sir J. B. Lawes. The returns of acreage are available for a much longer period from the Board of Agriculture. The trade returns are taken from the statistical abstracts (or the annual statements) for each year.

The wheat crop of the United Kingdom becomes annually smaller, and consequently of less importance as a factor in the international grain trade. The decline in production is due to the abandonment of wheat growing, and not to a falling off in the productiveness of the soil or to inferior farming. The yield per acre for the whole kingdom during the years 1896–1900 was as follows:—

Bushels per Acre.

1900.	1899.	1898.	1897.	1896.
28·61	32·76	34·75	29·07	33·63

This gives an average for the quinquennium of 31·79 compared with 29·63 bushels per acre for the first five years of the period when official returns were first collected (1884–88). The rise in the acreage yield is probably due to the fact that the less fertile wheat land is being abandoned, and only the better class kept under cultivation. The only other countries, making current returns, which come near the British average are New Zealand, with about an equal return; Belgium, 28·10; Holland, 28·08; Germany, 24·17; and Sweden, 24·03. All other countries return a yield of less than 20 bushels. Also in the cultivation of barley and oats no other nation raising these cereals on a large scale comes anywhere near the British average yield of 34 bushels of the former and 40 bushels of the latter per acre.

The consumption of wheat per head of the population for all purposes during the period 1891–1900 averaged 5 bushels and 54 ℔ (or including what has been used for seeding, 6 bushels 2 ℔). Taken on a five years' basis, the consumption works out at 5 bushels 51 ℔ per head; so that it would appear as if prosperous trade had the effect of lessening the consumption of bread-stuffs.

1896	7,281,000	6,263,235	9,728,000	20,357,000	811,000	622,000
1897	7,037,000	4,106,609	9,077,000	20,444,000	831,000	656,000
1898	9,360,600	6,224,780	9,341,000	21,572,000	908,000	607,000
1899	8,407,500	5,837,387	9,315,700	20,936,500	945,000	553,300
1900	6,790,000	4,576,812	8,570,000	20,640,000	933,000	509,000
1901	6,700,000	.	8,450,000	20,250,000	..	..

From 1870 to 1883 inclusive are unofficial estimates.

Between 1885 and 1899 the respective proportions of native and foreign bread-stuffs consumed for all purposes in Great Britain were as follows, shown in three periods of five years each:—

	English Wheat.	Foreign Wheat.	Foreign Flour.	Total Native and Foreign.
	Qrs.	Qrs.	As qrs. Wheat.	Qrs.
1885–89	9,260,000	13,100,000	5,400,000	27,760,000
1890–94	8,840,000	15,200,000	6,200,000	30,240,000
1895–99	7,360,000	16,200,000	6,800,000	30,360,000

N.B.—Allowance has not been made for re-exports, which amount to 300,000 quarters annually.

It is worthy of note that the proportion which the flour imports bear to the total quantity of wheat used is growing larger, the percentage in the first period being 24 per cent., in the second 25 per cent., and in the third 29 per cent. Divided up among the population, it appears that the per caput consumption of the manufactured article imported from abroad averaged 1·17 bushels in 1885–89; 1·29 bushels in 1890–94; and 1·35 bushels in 1895–99. This is a matter for disappointment to the British millers, who seemed for a while to have stemmed the imports of foreign-made flour; for after the great importation of the year 1891 the quantity declined steadily, until in 1897 it had fallen off to 16 per cent.; but only to rise again in 1898 and 1899 to a higher level than ever before:—

A reference to the annual statement showing the exportation of grain and flour affords little cause for gratification. There is a steady but small increase in the exports of flour, but they do not yet amount to 5 per cent. of the imports.

The chief ports which handle foreign grain are Liverpool, London, Hull, and Bristol, followed at a considerable distance by Manchester, Cardiff, Gloucester, Plymouth, Newcastle, and Southampton. Of wheat alone Liverpool is far ahead as an importer, followed by Hull and London. The five chief ports importing the largest proportion of each cereal and flour in 1900 were :—

Wheat, quarters.

Liverpool.	Hull.	London.	Bristol.	Leith.
4,776,000	2,766,700	2,200,000	909,000	645,000

Flour, sacks.

London.	Liverpool.	Glasgow.	Belfast.	Leith.
3,116,000	1,700,000	1,625,000	507,000	405,000

Maize, quarters.

Liverpool.	London.	Bristol.	Glasgow.	Belfast.
3,699,000	1,587,000	987,000	954,000	825,000

Barley, quarters.

Bristol.	London.	Hull.	Leith.	Liverpool.
988,000	655,000	654,000	472,000	346,000

Oats, quarters.

London.	Hull.	Bristol.	Liverpool.	Leith.
4,623,000	645,000	275,000	268,000	231,000

The favourite wheats imported into Great Britain are North American, Canadian, Argentine, Australian, and Indian ; Russian and Rumanian sorts being less in demand as a general rule.

ANNUAL IMPORTS IN CEREAL YEARS OF DIFFERENT SORTS.

	1899-90.	1898-99.	1897-98.	1896-97.
	Qrs.	Qrs.	Qrs.	Qrs.
North American	8,763,000	10,232,000	9,403,000	8,450,000
Argentine .	3,905,000	1,630,000	898,000	390,000
Australian .	930,000	464,000	16,000	...
Indian . .	870,000	2,069,000	1,322,000	150,000

Rumanian .	...	8,000	70,000	1,085,000
Other sorts .	294,000	201,000	649,000	1,978,000
Total .	15,197,000	15,391,000	14,834,000	15,668,000

France (population, 38,595,500 ; census 1901).—Prior to 1874 France raised the biggest crop of wheat of any country in the world, but America has now taken the lead, followed by Russia. There has been very little change in the area under wheat in France. For a long time it has stood at 17,000,000 acres, but of late years there has been a distinct improvement in the standard of farming, with the result that the yield per acre has been increased by 2 bushels. But it is still a long way below the British standard, being about one-third less. The acreage, production, and yield per acre, according to the harvest of 1899, were as follows :—

	Acreage.	Total Crop.	Yield per Acre.
		Bushels.	Bushels.
Wheat and Spelt . .	17,142,000	353,152,000	20·6
Barley	1,991,000	43,905,000	22·1
Oats	9,730,000	262,078,000	27·0
Rye	3,677,000	64,836,000	17·6
Maize	1,385,000	24,785,000	10·9
Potatoes	3,864,000	485,966,000	126·0

The production over a series of years of the chief crops was as follows :—

1901	38,000,000	7,300,000	4,700,000	26,000,000	..	..	

Average yield crops of wheat in 1898, 1899, 1900, 20 bushels per acre.

The principal wheat port of the republic is Marseilles, for there trade is always active, even when such important ports as Havre and Dunkirk are quite idle. The first mentioned port is the great entrepôt for the trade in bonded wheat milling, and all the year round, and every season alike, fifty or sixty thousand quarters per week are taken in at Marseilles and manufactured into " paste," or re-exported in the shape of flour to French colonial possessions. When there is a serious crop failure in France such ports as Havre and Dunkirk become of great importance, as it is in the north of France wheat is mainly produced :—

1901	727,000	7,500	1,043,400	3,032,700	1,353,800	147,800	61,200

N.B.—In addition to the above imports there is a substantia quantity taken surreptitiously. France also uses a good deal o foreign wheat in the manufacture in bond of flour, semolina, biscuits and bread for exportation. These figures are shown in the "*Tableau Général du Commerce.*"

The consumption of wheat for all purposes in France is very great, as will be seen from the following figures, which give th

average for the period 1885–99, divided into three equal periods of five years each :—

	1885–89.	1890–94.	1895–99.
Total quarters	41,900,000	43,400,000	[a] 44,300,000
Per caput bushels	8·9	9·0	[a] 9·1

[a] Probably an over-estimate.

The favourite foreign wheat in France is Russian, but when a crop failure occurs all sorts are imported—Australian and Californian being well liked. North African wheat is nearly all taken in at Marseilles.

Germany (population, 56,345,014 ; census 1901).—The statistics of this country both for production and for exports and imports are from *Statistisches Jahrbuch für das Deutsche Reich.* There has been a rapid growth in the production of wheat, proceeding from a higher acreage yield and an increasing area. The area under crops, the out-turn, and the yield per acre are shown in the following statement for the year 1900 :—

	Acreage.	Total Crop.	Yield.
			Bushels per Acre.
Wheat	5,061,000	17,645,000 qrs.	27·9
Rye	14,708,000	39,277,000 ,,	21·3
Barley	4,125,000	16,550,000 ,,	32·1
Oats	10,183,000	51,465,000 ,,	40·3
Potatoes	7,950,000	40,585,000 tons [a]	5·1 tons

[a] 2·205 lb.

German agriculture, it will be seen, is now of a high standard, closely resembling the British. During 1885–1900 the total production of wheat and rye in Germany increased 50 per cent.; barley and oats, 30 per cent.; and potatoes, 40 per cent. The chief breadstuff in the Fatherland is rye ; the per capita consumption for all purposes amounts to 5·6 bushels, compared with 3·1 bushels of wheat, both taken on a five years' average. Notwithstanding the increased productiveness of German farms, it is a fact that the importation of foreign grain is becoming yearly more important. During 1885–1900 wheat imports trebled ; barley also ; while at the same time enormous quantities of maize were imported. The following tabular statements show the production, imports, and exports :—

PRODUCTION.

Year.	Wheat.	Rye.	Barley.	Oats.	Spelt.	Potatoes.

1900	5,943,500	4,103,100	4,307,300	3,354,600	6,357,900	265,900
1901	9,803,100	3,967,000	4,959,900	2,993,700	5,481,500	303,000

The chief grain port of Germany is Hamburg, followed at a long interval by Bremen and Stettin. In addition to the imports of foreign grain through these seaports, there is a very large trade carried on at Mannheim—the Rotterdam imports finding their way into Germany by the Rhine and other rivers and canals. German millers are beginning to take to all kinds of foreign wheat, but the most favoured sorts are Russian and Rumanian, red American following next, and sharing third place with Argentine.

Belgium (population, 6,815,504 ; census 1900).—The acreage and yield are taken from the official annual publication, *Annuaire Statistique de la Belgique.* The import figures are from the *Tableau Général du Commerce,* &c.

The following statement shows the acreage for 1895, but the crops for 1897 :—

	Acreage.	Total Crop.	Yield per Acre.
		Bushels.	Bushels.
Wheat and Spelt	528,000	15,300,000	29·0
Rye	699,939	19,770,400	28·2
Barley	100,000	3,513,000	35·1
Oats	614,000	28,676,000	46·7
Potatoes	457,187	108,556,000	238·0

Owing to the peculiar method adopted in arriving at the foregoing results, we are inclined to doubt the accuracy of the figures as to the yield per acre. The probability is the acreage was larger upon which the crop of 1897 was grown, and the average yield per acre somewhat less. The total consumption of wheat and rye in Belgium per annum is as follows :—Wheat, 7·1 ; rye, 3·0 bushels per caput.

1898	5,874,940	386,317	1,768,826	207,429	2,110,254	70,926
1899	6,301,885	131,509	1,706,782	333,899	2,387,128	189,829
1900	5,069,500	225,400	1,328,800	525,100	2,318,300	183,000
1901	6,858,500	296,000	1,308,000	327,700	1,743,700	163,000

Antwerp is the one port of Belgium monopolizing the grain trade—Ghent alone getting a little of the oats imported from Libau and Riga. Considerable quantities of grain are exported to the north of France and Germany. Frequently Antwerp has taken the lead of all the wheat-importing centres of the world, receiving over 6,000,000 quarters of wheat in a twelvemonth, as in 1899, 1895, and 1891.

Holland (population, 5,179,138; estimate 1900).—The production of cereals in the Netherlands is on a very small scale, and the agricultural statistics are not very closely up to date. Figures for 1897:—

	Acreage.	Total Crop.	Yield per Acre.
		Bushels.	Bushels.
Wheat and Spelt . .	154,000	4,174,000	27·1
Rye	527,000	11,561,000	21·9
Barley	90,000	3,621,000	40·2
Oats	331,000	15,625,000	47·2
Potatoes	373,000	75,517,000	202·0

The consumption of wheat and rye for all purposes during the five years ending 1900 averaged about $4\frac{3}{4}$ bushels of the former and $4\frac{1}{2}$ bushels of the latter; in the five years 1885–89 the quantities averaged $3\frac{4}{5}$ bushels of wheat and $4\frac{3}{4}$ bushels of rye.

The great wheat port of Holland is Rotterdam, through which and its extensive ramifications of rivers and canals large areas of northern Europe are fed with imported grain. This port, along with Liverpool and Antwerp, disputes the claim for first place as the chief wheat-importing port of the world. Holland, as will be seen from a glance at the foregoing table, re-exported about 12,000,000 quarters of grain out of the 16,000,000 quarters which she imported in 1899. Large quantities of all sorts of grain go up the Maas to the Rhine, to supply Germany and Switzerland.

Italy (population, 32,449,754; census 1901).—The statistics as to production are taken from the *Annuario Statistico Italiano*, and those for the trade in foreign grain from the *Movimente Commerciale del Regno St Italie.*

The cultivation of wheat, in virtue of a high protective duty, is maintained, and indeed slightly enlarged, but not in proportion to the increase in the population, neither does the importation increase, so that it would appear as if the standard of living was not being raised as it is in most other countries—Germany in particular. The only article which Italy is taking more freely now than in, say, 1890 is maize, of which also more is being produced.

The total amount of wheat and maize used annually in the two periods 1885–89 and 1895–99 was as follows:—

Years.	Wheat.	Maize.	Consumption per Head of Population.	
			Wheat.	Maize.
	Qrs.	Qrs.	Bushels.	Bushels.
1885–89	17,600,000	9,300,000	4·6	2·4
1895–99	18,100,000	10,000,000	4·5	2·5

N.B.—A good deal of pulse is consumed in Italy.

The following table shows the present acreage, crop, and yield per acre:—

	Acreage.	Total Crop.	Yield per Acre.
		Bushels.	Bushels.
[a]Wheat .	11,315,000	140,752,000	12·4
[a]Maize . .	4,831,000	77,440,000	16·0
[b]Oats . .	1,171,000	18,601,000	15·9
[a]Barley .	761,000	9,744,000	12·8
[b]Pulse . .	2,097,000	11,220,000	5·3

[a] Year 1896. [b] Year 1895.

The standard of farming must be very low in Italy, judging from the poor yields per acre:—

The chief grain ports of Italy are Genoa and Venice, the former being the receiving port for much of the wheat destined for Switzerland. The wheats imported into Italy in greatest quantities are those of Russia and Rumania, the hard wheat of Taganrog being in great demand for making maccaroni.

Spain (population, 18,826,000; census 1897).—Only in 1899 for the first time were Spanish agricultural statistics issued. Foreign Office returns:—

	Acreage under Crops, year 1899.	Estimated Total Crops.	Yield per Acre.
		Bushels.	Bushels.
Wheat . . .	9,048,662	97,680,582	10·8
Barley . . .	3,463,710	51,796,024	15·0
Oats . . .	931,578	12,386,000	13·3
Rye . . .	1,848,062	19,891,000	10·8
Maize . . .	1,159,720	23,913,000	20·6
Beans . . .	633,202	7,032,000	11·1

The consumption per head of wheat in the years 1896–97 appears to have been about $5\frac{1}{2}$ bushels. During the ten years ending 1899 the gross annual supply of wheat, native and imported, was as follows, in two periods of five years each:—

Period.	Native.	Foreign.	Total.
	Qrs.	Qrs.	Qrs.
1890–94	10,200,000	1,060,000	11,260,000
1895–99	11,700,000	700,000	12,400,000

The wheats of which Spain imports most are Russian and Rumanian, the chief receiving port being Barcelona. Formerly a good trade was done by Spanish millers in exporting flour to Cuba and Costa Rica, but this has now ceased.

1892	638,493	..	..	..	39,800
1893	1,925,868	..	..	..	56,400
1894	1,954,199	..	.	..	59,300
1895	932,305	..	..	..	14,900
1896	862,288	..	..	..	2,300
1897	651,953	..	..	..	13,500
1898	273,100	13,200	11,500	459,500	22,000
1899	1,714,500	3,700	3,900	241,500	173,900
1900	1,022,400	3,500	54,500	232 400	39.300
1901	674,100	263 000	77,000	312,000	22.500

Portugal (population, 5,428,800, including the Islands; census 1900).—Agricultural statistics are not easily obtainable for this country, and we have to take an estimate of M. Louis Grandeau of the year 1892 as our authority for the acreage and the average yield per acre.

	Acreage.	Total Crop.	Yield per Acre.
		Bushels.	Bushels.
Wheat	642,000	8,512,000	13·1
Maize	1,285,000	20,225,000	15·9
Rye	667,000	6,640,000	10·0
Barley	143,000	1,986,000	13·7
Oats	30,000	425,000	14·1
Potatoes . . .	74,000	8,211,700	111·0

All these yields are meagre in comparison with those of Northern Europe, but they seem about correct in relation to Spanish and Italian. The consumption of wheat in Portugal is small, working out at only $2\frac{1}{2}$ bushels per head; the cereal constituting the people's chief food being maize, of which it is estimated that between 6 and 8 bushels per head are used annually. The following tabular statements show the production, exports, and imports of the chief

cereals for a number of years. The chief ports of entry for wheat are Oporto and Lisbon, and the principal source of supply the United States of America.

PRODUCTION.

(*From the Corn Trade News.*)

Year.	Wheat.	Year.	Wheat.
	Qrs. 480.		Qrs. 480.
1890	810,000	1896	750,000
1891	875,000	1897	1,200,000
1892	800,000	1898	1,100,000
1893	750,000	1899	800,000
1894	1,250,000	1900	1,000,000
1895	800,000		

The exports of wheat are unimportant, but some flour is shipped annually.

IMPORTS.

1896	547,400	28,900	...	...
1897	650,600	63,480	10,320	...
1898	320,620	134,320	10,150	114,000
1899	461,400	376,100	...	...
1900	628,700	328,100	...	...

Portugal imported of oleaginous seeds 322,400 cwts. in 1900, and 263,500 in 1899 ; besides rice 344,900 cwts. in 1900, and 322,300 cwts. in 1899 ; and about 40,000 to 50,000 qrs. beans on an average enter this country.

Sweden (population, 5,136,441 ; census 1900).—Very complete and up-to-date statistics are issued by the Swedish Government, as will be seen from the annexed tabular statements. The acreage under crops is for 1898, the produce statistics being for the following year :—

	Acreage.	Total Crop.	Yield per Acre.
		Bushels.	Bushels.
Wheat	182,000	4,293,000	23·6
Barley	545,000	11,329,000	20·8
Oats	2,033,000	52,038,000	25·6
Rye	1,013,000	20,773,000	20·5
Potatoes	390,000	32,877,000	84·0

The consumption per head of wheat works out at only 1¼ bushels, but of rye it amounts to almost 5 bushels. The great crop, however, is oats, of which nearly 13 bushels per head are raised. The following tabular statements show the production of native, and the trade in foreign cereals for certain years. The largest quantities of wheat come from America, Russia, and Germany. The principal ports for grain are Stockholm and Calmar.

Norway (population, 2,231,395 ; census 1901).—As would be expected, this northern kingdom plays but a small part in the international grain trade. In 1890 the areas and yields of the chief crops were as follows :—

	Acreage.	Crop.	Yield per Acre.
		Bushels.	Bushels.
Wheat . .	10,833	256,800	23·8
Rye . . .	33,985	920,800	27·3
Barley . .	127,896	4,104,800	32·0
Oats . .	256,198	9,541,000	37·5

The two years for which complete estimates of the produce are available are 1890 and 1900 :—

	Wheat and Rye combined.	Barley.	Oats.	Potatoes.	Other Corn.
	Qrs.	Qrs.	Qrs.	Bushels.	Qrs.
1890	147,000	513,100	1,192,700	23,212,800	174,600
1900	145,000	475,000	1,154,000	22,216,000	176,000

The imports comprise substantial quantities of rye, barley, wheat flour, and rye meal, and a little wheat. The exports are small, comprising about 5000 quarters of oats and 6000 sacks of rye meal. The chief ports are, Moss (for Christiania), Stavanger, and Bergen. Wheat is imported from Russia and Germany ; rye from Russia, Germany, and United States of America ; flour and rye meal from Germany.

1899	42,000	885,700	527,500	101,000	260,000	350,000
1900	32,000	836,400	543,600	120,000	340,000	427,000
1901	30,000	927,000	507,000	..	..	..

Denmark (population, 2,464,770; census 1901).—The produce statistics are from *Hosten i Danmark*, and give the yield for 1900, and acreage and yield for 1896 :—

	Acreage.	Crop.	Yield per Acre.
		Bushels.	Bushels.
Wheat . .	84,812	3,550,290	41·9
Barley . .	689,660	20,453,158	29·7
Oats . .	1,083,458	37,078,120	34·2
Rye . . .	716,648	19,328,472	27·0
Potatoes . .	129,185	20,888,942	162·0

This remarkably heavy yield per acre of wheat has always been questioned, for there is no other country in the world that has succeeded in raising its yield per acre, over a wide area, above 34 bushels; and it is thought that some mistake has crept in among the area or the produce statistics for the year 1896. The consumption of cereals per head in Denmark during recent years has averaged about $2\frac{1}{3}$ bushels of wheat and $8\frac{1}{2}$ bushels of rye.

The following tabular statement shows the production of native, and the trade in foreign, grain and flour for a number of years.

The chief port for grain is Copenhagen, and the principal sources of supply are Germany, Russia, and the United States of America, for wheat and flour; Russia and Germany for rye; Russia for barley; and America for maize, of which immense quantities are annually imported.

Switzerland (population, 3,313,817; census 1900).—There are no official returns for the areas under crops, but the trade statistics are quite complete and up to date. The consumption per head of wheat during the period 1896–1900 averaged nearly 6 bushels, and of rye rather over 6 bushels; but probably the great number of tourists who visit Switzerland in the summer disturbs these calculations slightly. The crops of Switzerland are usually estimated at between 500,000 and 600,000 qrs. of wheat, 2,500,000 qrs. of rye, 1,800,000 qrs. of barley, and 8,500,000 qrs. of oats. The exports are only trifling, but the imports are considerable, as will be seen from the following statement :—

1899	1,751,100	..	49,800	675,300	293,300	335,400
1900	1,646,200	..	49,400	650,600	230,300	234,800
[a] 1901	1,700,000	.	43,000	700,000	220,000	240,000

[a] Cereal year.

As Switzerland has no seaboard, the foreign grain is brought from the ports of other countries in bond, and received at Basel, Zürich, and other frontier towns from Rotterdam, Marseilles, Genoa, &c. The chief sources of supply are Russia for wheat and oats, and France for flour.

Greece (population, 2,433,806; census 1896).—According to the estimates of the *Corn Trade Year-Book*, the wheat crop has steadily diminished. in size, until it amounted in 1900 to only about one-third of what it was in 1890 :—

Wheat Crop in Quarters.

1890.	1891.	1892.	1893.	1894.	1895.
850,000	1,000,000	940,000	900,000	620,700	450,000
1896.	**1897.**	**1898.**	**1899.**	**1900.**	**1901.**
600,000	400,000	400.000	200,000	300,000	400,000

The imports of wheat now amount to about 700.000 quarters annually, so that the indicated per capita consumption is $3\frac{1}{3}$ bushels. The exports are insignificant.

The Piræus is the port where most of the foreign grain arrives. The plains of Thessaly are where the major part of the native wheat crop is raised.

Mexico (population, 13,545,462; census 1900).—The production is estimated as follows :—

PRODUCTION.

Year.	Wheat.	Barley.	Maize.	Year.	Wheat.	Barley.	Maize.
	Qrs. 480.	Qrs. 8 bush.	Qrs. 8 bush.		Qrs. 8 bush.	Qrs. 8 bush.	Qrs. 8 bush.
1890	1,500,000	..	..	1895	1,700,000	..	..
1891	1,500,000	..	..	1896	1,900,000	.	..
	Qrs. 8 bush.			1897	1,212,000	1,074,600	14,812,600
1892	1,705,500	631,700	9,112,600	1898	2,000,000	..	..
1893	2,100,000	..	..	1899	2,000,000	.	..
1894	2,500,000	..	..	1900	2,000,000	.	.

The imports chiefly consist of maize from America, amounting occasionally to 1,000,000 quarters. The exports are only trifling.

South Africa.—The cultivation of cereals is not carried on in any of the South African colonies with great success. The statistics for Cape Colony and Natal are as follows :—

Cape Colony (population, 2,265,556; estimated December 1899).—

[a] These figures relate to cultivation by European population only, and include sweet potatoes.

China (population, including dependencies, 400,000,000; estimate).—Very little has ever been published on the agricultural productions of this country. The cereal crops, whatever their quantity, are sufficient to provide for the populations of most of the Chinese provinces; but there are no reserves, and whenever a bad harvest occurs, famine immediately sets in. The following statistics are taken from *Returns of Trade* for 1898, printed at Shanghai:—Imports: wheat, 42,412 quarters; flour, 203,773 sacks; beans, 776,000 quarters. Exports: wheat, 40,749 quarters; flour, 22,778 sacks; beans, 1,805,781 quarters. In 1897 the imports of beans amounted to 568,611 quarters, but no figures are given for flour or wheat. Hong Kong is credited with importing about 800,000 sacks of flour per annum from America.

Korea (population, 17,000,000; census 1897).—In 1898 the exports amounted to £7000 worth of wheat, £111,000 worth of beans, and £278,000 worth of rice; the imports to £44,000 worth of millet and £39,000 worth of rice.

Gramont, Antoine Agénor Alfred, DUC DE (1819–1880), French statesman, was born at Paris on the 14th of August 1819, and came of an old aristocratic family. After the usual educational course he entered upon a diplomatic career. In 1848 he married a Scottish lady, Miss Mackinnon. After the *Coup d'état* of 2nd December 1851 he began to rise with the fortunes of Louis Napoleon, who was his personal friend, and he was employed upon various diplomatic missions. In 1857 he was sent as ambassador to Rome. The creation of the kingdom of Italy, as the result of the campaign of 1859, caused his position at the Papal court to become extremely embarrassing. He was consequently recalled to France, and from 1861 to 1870 he was ambassador at Vienna. On 16th May 1870 he was appointed minister of foreign affairs in the Ollivier cabinet. In this capacity he incurred much obloquy by forcing on the war with Germany. The duc de Gramont first announced to the king of Prussia that the candidature of Prince Leopold of Hohenzollern for the throne of Spain could not be permitted; and then, after the prince withdrew, he insisted that no member of the Prussian family should be put forward in his stead. Germany refused to give any such pledge, which she described as an utterly unnecessary and humiliating demand, and this led to the declaration of war by France in July. In the French legislative body, on 11th July, the duc de Gramont said, "Up to the present all the European cabinets appear to admit the legitimacy of our complaints." This was promptly contradicted, so far as Great Britain was concerned, by Earl Granville, who added, however, that Great Britain had exerted her influence for the preservation of peace. On 15th July M. Ollivier in the legislative body, and the duc de Gramont in the Senate, announced that France was at war. After the revolution of September the duc de Gramont fled to England. In 1872 he published a defence of his conduct under the title of *La France et la Prusse avant la Guerre*. Soon afterwards he returned to France, where he devoted himself to financial undertakings. He died in Paris on 18th January 1880. (G. B. S.)

Granada, a maritime province of Southern Spain. Its area is 4937 square miles, divided into fifteen administrative districts and 205 parishes. The province is still badly off for means of communication, having only one railway from Granada to Bobadilla, the junction with the lines to Cordoba, Malaga and Ronda, Seville and Algeciras, in all 57 miles. The roads also are in a very incomplete and unsatisfactory condition. The sugar-cane and beetroot industries have been developed with excellent results, and they have further increased since the loss of the West Indian colonies and the Philippines. The sugar factories are at Loja, Antequera, Flora, Motril, Salobreña, and the Vega of Granada. There are also tanneries, foundries, and manufactories of woollen, linen, cotton, and rough frieze stuffs, cards, soap, liqueurs, gunpowder, brandy, and machinery. Its ports on the Mediterranean are Motril, Almuñecar, Albuñol. The official records show forty-three mines productive and 758 unproductive. The former give occupation to about one thousand hands, and in 1898 turned out 49,688 tons of coal. The province is one of the richest in live stock, especially mountain sheep and goats. The figures for 1897 are 10,052 horses, 38,314 mules, 38,630 asses, 18,466 cattle, 328,180 sheep, 108,272 goats, and 51,634 pigs. At the same time 111,000 acres were devoted to wheat, 76,000 acres to barley, 75,500 acres to rye and oats, 12,000 acres to pod fruit, 35,000 acres to beans and garbanzos, 13,000 acres to vines, and 52,000 acres to olives. Population (1887), 484,341; (1897), 477,768.

Granada, the capital of the above province. Few cities in Spain have more educational establishments. Besides the university there are an institute for higher instruction, a training school for teachers, a school of fine arts, and twenty-two primary schools. The provincial library is now practically empty. There are archæological and painting museums, besides that of the Alhambra; also a royal central seminary, an ecclesiastical college, twelve hospitals and orphanages for both sexes, and in one of the convents a leper hospital. Granada has some thriving local industries—manufactures of liqueurs, paper, soap, and coarse woollen and linen stuff—and an active trade in agricultural products from the fertile Vega. Population (1887), 73,000; (1897), 75,054.

Granada, a city of Nicaragua, Central America. It is situated on the north-west shore of Lake Nicaragua, 32 miles N.W. of Managua, the capital of the republic, with which it is now connected by rail. The journey to the Pacific port of Corinto now occupies only about twelve hours—by steamer on Lake Managua to Momotombo, and thence to Corinto by rail 58 miles. From the railway station of Granada at the wharves on Lake Nicaragua there is a tramway to the market buildings one mile distant. There is an ice factory established, but the special industry of the city is the manufacture of "Panama chains," made of gold wire. In the environs are large cacao plantations. Population, 19,000.

Grand Bassa. See LIBERIA.

Grand Forks, capital of Grand Forks county, North Dakota, U.S.A., on the western bank of the Red River, and on the Northern Pacific and the Great Northern railways, at an altitude of 830 feet. It is in the midst of the great Red River valley wheat region, and much of its business consists in the handling of wheat. Population (1880), 1705; (1890), 4979; (1900), 7652, of whom 2781 were foreign-born.

Grand Island, capital of Hall county, Nebraska, U.S.A., in 40° 56′ N. and 98° 21′ W., on the broad, level bottom-lands of the Platte river, at an altitude of 1866 feet. The plan is regular, the broad streets running at angles of 45° with the compass points. It has three railways, the Union Pacific, the Burlington and Missouri River, and the St Joseph and Grand Island. It is the seat of Grand Island College, a Baptist co-educational institution, founded in 1892. This had, in 1899, 10 instructors and 125 students. The city is in a rich agricultural region, and its principal business consists in handling grain and cattle. It contains works of the Union Pacific

Railway. Population (1880), 2963; (1890), 7536; (1900), 7554, of whom 1339 were foreign-born and 38 negroes.

Grand Junction, capital of Mesa county, Colorado, U.S.A., in the broad desert valley of Grand River, at the mouth of the Gunnison, at an altitude of 4579 feet. The Grand River valley, when irrigated, is extremely fertile, and produces vast quantities of fruit, which is handled here. It is also the meeting-point of the Colorado Midland, the Rio Grande Western, and two branches of the Denver and Rio Grande Railway. Population (1880), 859; (1890), 2030; (1900), 3503, of whom 358 were foreign-born and 52 negroes.

Grand Rapids, capital of Kent county, Michigan, U.S.A., in 42° 58′ N. and 85° 40′ W., at the rapids in Grand River, at an altitude of 610 feet. The city is regularly laid out, is divided into twelve wards, is well paved, largely with asphalt and wooden blocks, and has a municipal water supply. It is entered by six railways, affording communication in all directions and giving the city a large commerce. Grand Rapids is a manufacturing city of great importance, which is due in no small part to the water power in Grand River. In 1890 there were 869 manufacturing establishments, with a capital of $15,945,947, employing 13,282 hands, and with a product valued at $19,851,181. The leading products were furniture, valued at $5,638,916; flour, $1,558,845; and lumber, $2,319,495. In the manufacture of furniture this city is one of the foremost in the United States. The assessed valuation of real and personal property in 1900 was $43,264,021, the net debt of the city $1,889,824, and the rate of taxation $20·42 per $1000. Population (1880), 32,016; (1890), 60,278; (1900), 87,565, of whom 23,896 were foreign-born and 604 negroes. The death-rate in 1900 was 14·4.

Grangemouth, a police burgh and seaport of south-east Stirlingshire, Scotland, near the confluence of the rivers Carron and Forth, 3 miles east-north-east of Falkirk. Standing at the entrance to the Forth and Clyde Canal, it is one of the most important harbours in Scotland. The docks cover an area of 28 acres, and there are timber basins covering 32 acres, the total quayage being 2290 yards. A large extension is being carried out at an estimated cost of £1,000,000. The new docks will be 200 acres in extent, with an entrance 15 feet deep in the Forth. At the end of 1898, 55 vessels of 15,589 tons were registered. In 1888, 1962 vessels of 721,724 tons entered; in 1898, 2389 vessels of 1,089,166 tons entered. Imports rose in value from £1,902,753 in 1888 to £2,416,452 in 1898; and exports from £705,740 in 1888 to £2,153,368 in 1898. Timber, pig-iron, and iron ore are the principal imports, while 662,027 tons of coal were exported in 1888, and 1,479,946 in 1898. There is a shipbuilding yard and various accompanying industries. Grangemouth has regular steamer communication with London, Christiania, Hamburg, Rotterdam, and Amsterdam. There is a "classic" town hall, a public institute, a free library, and a public park. Population (1901), 7968.

Grant, Sir Alexander, 8th Bart. (1826–1884), British scholar and educationalist, was born in New York, 13th September 1826. After an early childhood spent in the West Indies, where his father owned property, he was educated at Harrow and Oxford. He entered Oxford as scholar of Balliol, and subsequently held a Fellowship at Oriel from 1849 to 1860. He made a special study of the Aristotelian philosophy, and in 1857 published an edition of the *Ethics* (4th ed. 1885) which became a standard text-book at Oxford. In 1855 he was one of the examiners for the Indian Civil Service, and in 1856 a Public Examiner in Classics at Oxford. In the latter year he succeeded to the baronetcy. About the same time he married the daughter of Professor Ferrier of St Andrews. In 1859 he went to Madras with Sir Charles Trevelyan, and was appointed Inspector of Schools; the next year he removed to Bombay, to fill the post of Professor of History and Political Economy in the Elphinstone College. Of this he became Principal in 1862; and, a year later, Vice-Chancellor of Bombay University, a post he held from 1863 to 1865 and again from 1865 to 1868. In 1865 he took upon himself also the duties of Director of Public Instruction for Bombay Presidency. In 1868 he was appointed a member of the Legislative Council. In the same year, upon the death of Sir David Brewster, he was offered and accepted the post of Principal of Edinburgh University, which had conferred an honorary LL.D. degree upon him in 1865. From that time till his death (which occurred in Edinburgh, 30th November 1884) his energies were entirely devoted to the well-being of the University, his zeal in connexion with which was fully recognized. The institution of the Medical School in the University was almost solely due to his initiative; and the Tercentenary Festival, celebrated in 1884, was the result of his wisely directed enthusiasm. In that year he published *The Story of the University of Edinburgh during its First Three Hundred Years*. He was created Hon. D.C.L. of Oxford in 1880, and Hon. Fellow of Oriel College in 1882.

(R. F. S.)

Grant, James (1822–1887), British novelist, was born in Edinburgh, 1st August 1822, being the son of a military officer. Between 1832 and 1839 his father was quartered in Newfoundland, and James Grant was with him. In 1839, however, he returned to England and entered the 62nd Foot as an ensign, but in 1843 he resigned his commission and left the service. He then devoted himself to writing, first magazine articles, but soon a profusion of novels, full of vivacity and incident, and dealing mainly with military scenes and characters. For many years he was a favourite author in this kind. His best stories, perhaps, were *The Romance of War* (his first, 1846), *Bothwell* (1851), *Frank Hilton; or, The Queen's Own* (1855), *The Phantom Regiment* and *Harry Ogilvie* (1856), *Lucy Arden* (1858), *The White Cockade* (1867), *Only an Ensign* (1871), *Shall I Win Her?* (1874). Grant also wrote *British Battles on Land and Sea* (1873–75), and other books of general reading, of which one to which permanent value attaches was his great work, in three volumes, on *Old and New Edinburgh*. In 1875 he became a Roman Catholic. He died on 5th May 1887.

Grant, James Augustus (1827–1892), British traveller and explorer, was born at Nairn in 1827. After a course of study at Marischal College, Aberdeen, he was appointed to the Indian army in 1846, and subsequently rose to be lieutenant-colonel. He served throughout the whole of the Mutiny, and for his services received the Mutiny medal with Lucknow clasp. From 1860 to 1863 he was in Egypt with Captain Speke, exploring the sources of the Nile. On his return he was created C.B., in September 1866. Two years later he served in the Intelligence Department of Lord Napier of Magdala's Abyssinian expedition; for this he was made C.S.I., and was awarded the Abyssinian medal. Shortly after his return from Abyssinia he married. He was awarded the gold medal of the Royal Geographical Society in 1884, and, at various times, distinctions from British and foreign learned societies. He was Justice of the Peace and Deputy-Lieutenant of his native county, and the later years of his life were spent at Nairn. He died at Nairn, 11th February 1892. Besides contributions

to the journals of various learned societies, he published *A Walk across Africa* (1864) and *Khartum as I Saw it in 1863* (1885). (R. F. S.)

Grant, Sir Patrick (1804–1895), British field marshal, was the second son of Major John Grant, 97th Foot, of Auchterblair, Inverness-shire, where he was born on 11th September 1804. He entered the Bengal Native Infantry as ensign in 1820, and became captain in 1832. He served in Oude from 1834 to 1838, and raised the Hariana Light Infantry. Employed in the adjutant-general's department of the Bengal army from 1838 until 1854, he became adjutant-general in 1846. He served under Sir Hugh Gough at the battle of Maharajpur in 1843 (bronze star and a brevet majority), was adjutant-general of the army at the battles of Mudki in 1845 (twice severely wounded), and of Firozshah and Sobraon in 1846 (medal with three clasps, a brevet lieutenant-colonelcy, and a C.B.). He took part in the battles of Chilianwala and Gujarat in 1849 (medal with two clasps, colonel, and aide-de-camp to the Queen). He served also in Kohat in 1851 under Sir Charles Napier (medal with clasp). Promoted major-general in 1854, he was commander-in-chief of the Madras army from 1856 to 1861. He was made K.C.B. in 1857, and on General Anson's death was summoned to Calcutta to take supreme command of the army in India. From Calcutta he directed the operations against the mutineers, sending forces under Havelock and Outram for the relief of Cawnpore and Lucknow, until the arrival of Sir Colin Campbell from England as commander-in-chief, when he returned to Madras. On leaving India in 1861 he was decorated with the G.C.B., and made colonel of the 104th Foot and later of the Seaforth Highlanders. He was promoted lieutenant-general in 1862, was governor of Malta from 1867 to 1872, was made G.C.M.G. in 1868, promoted general in 1870, field marshal in 1883, and colonel of the Royal Horse Guards and gold-stick-in-waiting to the Queen in 1885. He married as his second wife, in 1844, Frances Maria, daughter of Lord (then Sir Hugh) Gough. He was governor of the Royal Hospital, Chelsea, from 1874 until his death there on 28th March 1895. (R. H. V.)

Grant, Robert (1814–1892), British astronomer, was born at Grantown, Scotland, on 17th June 1814. In early youth he exhibited marked ability, but at the age of thirteen the promise of a brilliant career was clouded by a prolonged illness of such a serious character as to incapacitate him from all school-work for six years. At the age of twenty, however, his health greatly improved, and he set himself resolutely, without assistance, to repair the disadvantages of his earlier years, devoting himself to the study of Greek, Latin, Italian, and mathematics. Astronomy also occupied much of his attention at this time, and he was encouraged in the study of this subject by the interest attaching to the return of Halley's comet in 1835, and the annular eclipse of the sun of 15th May 1836, which he successfully observed. After a short course at King's College, Aberdeen, he obtained employment in his brother's counting-house in London, but still devoted his leisure hours to a systematic study of astronomy and mathematics. It was during this period that the idea occurred to him of writing a history of physical astronomy. For some time he had been accumulating materials suitable for such a history, but before definitely commencing the work he had to search, amongst other records, those of the French Academy, and for that purpose took up his residence in Paris in 1845, supporting himself by giving lessons in English. Returning to London in 1847, he devoted the next five years to the preparation of his classic work, *The History of Physical Astronomy from the Earliest Ages to the Middle of the Nineteenth Century*. This was first published in parts in *The Library of Useful Knowledge*, but after the issue of the ninth part this mode of publication was discontinued, and the work appeared as a whole in 1852. The main object of the work is, as expressed by the author, "to exhibit a view of the labours of successive inquirers in establishing a knowledge of the mechanical principles which regulate the movements of the celestial bodies, and in explaining the various phenomena relative to their physical constitution which observation with the telescope has disclosed." The lucidity and completeness with which a great variety of abstruse subjects were treated, the extent of research, and the maturity of judgment it displayed, were remarkable, the more so when we consider that this was the first published work of one who enjoyed no special opportunities, either of acquiring materials or of discussing the subjects it treats of with others engaged in similar pursuits. The book at once attracted the attention of astronomers, and took a leading place in astronomical literature. In 1856 the gold medal of the Royal Astronomical Society was awarded to Grant for his work. In 1859 he succeeded Nichol as professor of astronomy in the University of Glasgow, and took up his residence at the Glasgow Observatory during the following year. From time to time he contributed astronomical papers to the *Monthly Notices*, *Astronomische Nachrichten*, *Comptes Rendus*, and other scientific serials, but his principal work after his appointment to Glasgow consisted in determining the places of a large number of stars with the Ertel transit-circle of the Glasgow Observatory. The results of these labours, extending over a period of twenty-one years, are contained in the *Glasgow Catalogue of 6415 Stars*, published in 1883. This was followed in 1892 by the *Second Glasgow Catalogue of 2156 Stars*, published a few weeks after his death, which took place on the 24th October 1892. (A. A. R*.)

Grant, Ulysses Simpson (1822–1885), American soldier, and eighteenth President of the United States, was born at Point Pleasant, Ohio, 27th April 1822. He was a descendant of Matthew Grant, a Scotsman who settled in Dorchester, Mass., in 1630. His earlier years were spent in helping his father in the work upon his farm in Ohio. In 1839 he was appointed to a place in the military academy at West Point, and it was then that his name assumed the form by which it is generally known. He was christened Hiram, after an ancestor, with Ulysses for a middle name; in those days it was fashionable to call men by Greek and Roman names. As he was usually called by his middle name, the Congressmen who recommended him for West Point supposed it to be his first name, and generously added thereto the name of his mother's family, Simpson. Grant's career at West Point was not especially brilliant; he was the best horseman of his class, and took a respectable place in mathematics, but he only ranked twenty-first in a class of thirty-nine. In September 1854 he went with his regiment to join the forces of General Taylor in Mexico; there he took part in the battles of Palo Alto, Resaca de la Palma, Monterey, Cerro Gordo, and Churubusco, and was at the storming of Chapultepec. He was breveted captain for gallantry. After the close of the war he married, and was for a while stationed in California, but in 1854 he resigned his commission. He had acquired a taste for liquor, which impaired his usefulness and injured his reputation in the army. For the next six years he lived in St Louis, earning a scanty subsistence by dealings in real estate. In 1860 he moved

to Galena, Illinois, and became a clerk in a hardware store kept by his father. At that time his earning capacity seems not to have exceeded 800 dollars a year, and he was regarded by his friends as a broken and disappointed man.

After the outbreak of the Civil War, in the following year, he offered his services to the United States Government, but no heed was paid to him. After some vexatious delay, he obtained from the governor of Illinois a commission as colonel of volunteers, and about the 1st of August he was promoted to the rank of brigadier-general and placed in command of a district of the western department under General John Pope. The Confederate General Polk had occupied the bluffs at Columbus and was threatening to seize the town of Paducah, situated at the confluence of the Tennessee river with the Ohio. It was of the utmost importance that the latter step should be prevented, and Grant, acting on his own responsibility, moved rapidly forward and seized Paducah, 6th September 1861. In November he made a demonstration in Missouri, and fought at Belmont his first battle, in which both sides claimed the victory. Three months later came his first great achievement, when he captured Fort Henry on the Tennessee river and Fort Donelson on the Cumberland. This great victory, in which 15,000 Confederates were taken prisoners, broke through the enemy's first line of defence, and compelled them to fall back upon Corinth in Mississippi. His next military operation was directed against Corinth, where General Sidney Johnston had accumulated an army of about 40,000 men. On arriving at Pittsburg Landing on the Tennessee river, some 20 miles from Corinth, Grant occupied a very strong position on the left bank, intending to hold it until the arrival of General Buell with his army from Nashville. After the junction of the two armies, amounting to more than 70,000 men, it was intended to move in overwhelming force on Corinth.

Battle of Shiloh.

When Johnston learned of Grant's presence at Pittsburg Landing with no more than 40,000 men, he decided to advance suddenly and surprise him, in the hope of winning a victory before Buell's arrival. Circumstances so delayed the operation that Buell's advance division had arrived at Savannah, only 9 miles below Pittsburg Landing, on the evening before the attack was made. There has been much discussion as to whether Grant was really surprised on the Sunday morning, 6th April 1862, when the Confederates charged upon his camp. It is perfectly clear that he was not aware of the presence of Johnston's force in his neighbourhood, and did not expect any attack to be made before the middle of the week. When the firing began on Sunday morning Grant was 9 miles distant at Savannah. The division of Lew Wallace, 7000 men, was at Crump's Landing, 5 miles below the scene of the battle. The position at Pittsburg Landing, where the principal command was exercised by Generals M'Clernand and Sherman, was a strong one, protected on three sides by creeks, which were swollen with backwater from the great river. The open front towards the south-west, marked by a rude meeting-house known as Shiloh, ought to have been protected by earthworks; this precaution, however, had been neglected. Johnston's plan was to attack by his right flank and cut off the Union army from Pittsburg Landing, which would involve its destruction or capture; but his attack was not correctly planned for that purpose. His force was not sufficiently massed upon his right, and his main blow was directed too near the Federal centre. The attack was conducted with magnificent gallantry, but the resistance of the Federal troops was very obstinate, and although their organization was much impaired, it was with great slowness that they were pushed back. About the middle of the forenoon the Union general, Benjamin Prentiss, secured a difficult position, since known as the Hornet's Nest, and maintained it until late in the afternoon despite all the efforts of the Confederates. Early in the afternoon, while assaulting this position, Johnston was killed, and the command devolved upon General Beauregard. At nightfall it was manifest that the Confederate attack had failed. Lew Wallace's division had been greatly delayed in its march by imperfect information, and Nelson's division of Buell's army had been equally delayed by the detestable spring roads, but at nightfall both these divisions arrived upon the battlefield, adding 15,000 fresh men to the Union force; and so many steamboats had now been collected at Savannah that two more of Buell's divisions were comfortably brought up the river during the night. It was evident on Monday that Beauregard's battle was fought, not so much in the hope of victory, as in order to secure an unmolested retreat. This he accomplished. In the afternoon he withdrew his army with much skill, leaving the Federals too weary to pursue. In this great battle more than 20,000 men were killed and wounded, and the Federals lost besides 3000 prisoners. It was an important victory for the Federals, inasmuch as it decided the fate of Corinth; but those who blamed Grant for the surprise were perhaps quite as many as those who praised him for the victory. His position during the summer was a trying one, since Halleck came and took command of the entire force, thus placing Grant second in command, without assigning him any important duties. The campaign was conducted by Halleck with such feebleness that the advantages hitherto gained were in great part thrown away. For the loss of Corinth the Confederates consoled themselves by fortifying Vicksburg and Port Hudson on the Mississippi river, and Chattanooga on the mountainous confines of Tennessee and Georgia. The conquest of

General U. S. Grant.
(From a photograph by F. Gutekunst, Philadelphia.)

these two strongholds employed two great armies during the whole of the year 1863.

In the midsummer of 1862 Halleck was appointed general-in-chief of the armies of the United States, and in that capacity transferred his headquarters to Washington, leaving Grant in command at Corinth. His force had been so depleted by Halleck's scattered operations that the Confederates now made an attempt to drive him down the Tennessee river. The result was seen in the battles of Iuka and Corinth early in October 1862, when the Confederates were defeated by a portion of Grant's force under Rosecrans, for whom the victory won so much reputation that he was appointed to supersede Buell in command of the army in Tennessee. It was the prelude to Grant's first movement against Vicksburg. That city had been fortified and guarded by the Confederates in such wise that it was deemed impregnable, and it might well have been thought so. The place is situated on a steep and lofty bluff at the junction of the Yazoo river with the Mississippi. The latter flows in a serpentine course through a low flat basin about 40 miles in width. It is perpetually changing its course, and the land on either side is intersected in all directions by sluggish streams and stagnant lakes, the remnants of its abandoned channels. In such a country operations with an army are impossible. At long intervals, however, the river flows entirely on one side of its basin and washes the foot of the steep hills by which it is bounded. Wherever such a cliff occurred, as at Columbus, Memphis, and other points, it was defended by the Confederates, and when they lost it they lost the river down to the next similar point. Now the combination of circumstances at Vicksburg was peculiar. Its position was too lofty to be taken by the fleet unaided, but the only direction from which it could be safely approached by an army was from the rear, that is to say, from the east; and the correct line of approach was that of the Mississippi Central Railway, with Memphis for the Federal base of supplies. For an army coming either up or down the Mississippi the problem was almost insoluble. It was impossible to get in the rear of the city by landing to the north of it, for the approaches were there guarded by batteries on Haines Bluff which could shoot down any assailing column faster than it could advance. On the other hand, an army landing to the south of Vicksburg incurred the risk of starvation, since the guns of Vicksburg prevented supplies from passing down stream, while the guns of Port Hudson 200 miles below equally prevented them from passing up. Grant's first movement against Vicksburg was the correct one, along the Mississippi Central Railway; but because of his deficiency in cavalry, his line of communications was cut and he was obliged to retreat upon Corinth. Meanwhile a separate expedition under Sherman had been sent down the Mississippi river. It landed at Chickasaw Bayou, and attempted to storm the works at Haines Bluff in order to gain a foothold to the north of Vicksburg. This enterprise met with a bloody repulse. A period of intrigue succeeded, the result of which was that Grant felt obliged to abandon his first plan and take his whole army down the river to Vicksburg. After arriving on the west bank of the Mississippi opposite the mighty stronghold, the problem before him was to get his army into its rear. Two fruitless months were spent in attempts to navigate the intricate and tortuous system of bayous, in order either to land the army northwards without encountering the guns of Haines Bluff, or to carry supply-ships southwards by routes not commanded by the batteries of Vicksburg. Meanwhile Grant's popularity greatly declined, and President Lincoln was urged to remove him from command. But Lincoln's reply was, "I rather like the man; I guess we will try him a little longer." At this crisis Grant conceived a most daring scheme; and having heard it condemned by every one of his generals, he proceeded to try it on his own responsibility. On the 16th of April Porter's fleet was taken down the river below the city, sustaining slight damage from its batteries. Feints were made to the northward, while the body of the army was rapidly marched to Bruinsburg, about 25 miles below Vicksburg. A crossing was effected near that place, and the Confederates were defeated in an obstinate battle at Port Gibson. This obliged them to evacuate Grand Gulf, the strongest of the outposts to the southward. From Port Gibson Grant then proceeded to march north-easterly upon the city of Jackson, the capital of the state of Mississippi, intending to find and defeat Joseph Johnston, who was approaching to relieve Vicksburg. Grant's object was to throw himself between Johnston's army and that of Pemberton, the commander at Vicksburg, and to defeat them in detail. In order to do this, it was necessary for him to keep his army concentrated, and he could not spare troops to guard his line of communications with the Mississippi river. He therefore cut loose from his base altogether, and conducted this marvellous campaign upon such food as his men could carry in their knapsacks or seize in the course of their march. To avert certain ruin it was necessary that he should be victorious at every point; and he was. Having defeated Johnston in two battles, at Raymond and again at Jackson, he instantly faced about to the west and marched against Pemberton, who had come out to intercept his supposed line of communications. In a bloody battle at Champion Hill Pemberton was totally defeated, and his ruin was completed the next day at the Big Black river. Pemberton then retired into Vicksburg with the remnant of his force, while Sherman approached Haines Bluff in the rear and compelled the enemy to evacuate it. The supposed insoluble problem was now virtually at an end, for Grant's line of supplies from the northward was opened and made secure. Mindful of the possibility that Johnston might sufficiently recover strength to interrupt operations, Grant tried to carry Vicksburg by storm, and two assaults were made which were repulsed with great slaughter. He then resorted to siege operations, and by the third day of July the city was starved into submission. By this brilliant campaign Grant's reputation was at once raised to a very high pitch. He was made major-general in the regular army, and henceforth was allowed to have his own way in most things.

Operations at Vicksburg.

His next field of action was at Chattanooga. The Confederate commander, Braxton Bragg, had been driven out of that place by Rosecrans in a series of skilful manœuvres; but, in attempting to pursue Bragg through the difficult mountain country to the south, Rosecrans allowed the two wings and the centre of his army to become too widely separated, thus exposing himself to swift destruction. Bragg failed to seize the opportunity offered him, but nevertheless succeeded in bringing Rosecrans to battle in the valley of Chickamauga. There, in a murderous battle, in which nearly 40,000 men were killed or wounded, the Union right wing and centre were routed; but General Thomas, with almost incredible skill and bravery, not only saved the left wing, but very nearly retrieved the situation. Rosecrans retired his army into Chattanooga, but had not sufficient force to hold the crests of Lookout Mountain and Missionary Ridge, which were forthwith occupied by the Confederate army. This operation left the Union army without any good line of communications. The only route by which food could be brought was a long and difficult waggon road over a spur

of the Cumberland Mountains known as Waldron's Ridge. Drenching rains set in, the mules died on the route and blocked up the way, and presently the Union army suffered for want of food. Indeed, something like a famine set in, and nearly all the horses perished for want of forage. At this crisis Grant was appointed to command all the armies west of the Alleghanies, increased by the transfer of two corps from the army of the Potomac to that of the Cumberland. His first proceedings were to supersede Rosecrans by Thomas, and to order up Sherman from Vicksburg. By a beautiful series of operations an excellent line of communication was opened by General William Farrar Smith, and the sufferings at Chattanooga were relieved. On the arrival of Sherman's force it was moved by a circuitous and secret route to the north end of Missionary Ridge near Chickamauga station on the Dalton Railway, by which Bragg received his supplies. At this time Longstreet, who had been sent from Virginia to Bragg's assistance, and had taken part in the battle at Chickamauga, was engaged in a subsidiary operation. He had been imprudently sent away by Bragg to lay siege to Knoxville, and his line of communications was also the railway from Dalton. Bragg's left wing occupied the summit of Lookout Mountain, while his centre and right stretched along the crest of Missionary Ridge for a space of 5 or 6 miles. Under these conditions Grant's plan of battle was simple. His reinforcements from Virginia, commanded by Joseph Hooker, were in Lookout Valley. He proposed to make a demonstration with these troops which should engross Bragg's attention, while Sherman at the opposite extremity of the field should storm the northern end of Missionary Ridge, cut off Bragg from the Dalton Railway and crush his right wing, thus wrecking his army; but the battle, as fought, proceeded upon a very different plan. The accidental breaking of a pontoon bridge left in Lookout Valley one division of men which had been destined for Sherman's part of the field. This additional force so far strengthened Hooker that in the course of the fight which ensued upon Lookout Mountain he carried the whole position by storm, driving the Confederates down upon Missionary Ridge.

Battle of Missionary Ridge.

On the other hand, Sherman's enterprise was frustrated by an unforeseen obstacle. After he had surmounted the northern extremity of Missionary Ridge he was confronted by a yawning chasm which none of the Federal glasses had been able to detect, and as there were no good topographical maps, its existence was unknown. The crests beyond were crowned with Confederate artillery, and well manned. In these circumstances, the part that Sherman played, though a very useful one, was different from what had been intended. On the second day of the battle he attacked the heights before him; he was unable to carry them, but his pressure upon that vital point was so strong that it led Bragg to keep on reinforcing it at the expense of his centre, which was confronted by the army of General Thomas. Presently Grant, fearing for Sherman and wishing to stop this northward movement of Confederates, ordered four of Thomas's divisions to make a bayonet charge in front. They were to carry the Confederate works at the foot of Missionary Ridge and then halt and await orders. At that moment Grant was building better than he knew. The line of 20,000 men swept like an avalanche over the works at the foot of the ridge, and then in an uncontrollable spirit of victory kept on without orders, making their way up the perilous height. As they reached the top they broke through the Confederate centre in at least six different places, while at the same moment Hooker, who had come down from Lookout Mountain, overwhelmed Bragg's right and sent it tumbling in upon his routed centre. In a few moments the remnant of the Confederate army was a disorderly mob fleeing for life. This great victory secured for the northern army the line of the Alleghanies, as the capture of Vicksburg had secured the line of the Mississippi.

General-in-chief.

Grant's fame was now at its zenith. The rank of lieutenant-general was revived for him, and he was made general-in-chief of the armies of the United States. This appointment gave to the military operations of 1864 a greater coherence than that of former years. The theatre of war was now practically reduced to the seaboard states, Georgia, the two Carolinas, and Virginia. The Confederacy still possessed two formidable armies, one at Dalton in Georgia, commanded by Joseph Johnston, who had superseded Bragg, the other on the river Rapidan in Virginia, commanded by Lee, who seemed unconquerable. Grant's plan was to go directly by the overland route against Lee, while Sherman should advance from Chattanooga against Johnston. In Virginia, Grant took command in person. He now found himself opposed by a general of far greater calibre than any of those against whom he had contended in the west. The events of this last year added nothing to his military reputation. While they revealed in many ways Grant's fine soldierly qualities, it was nevertheless unquestionable that upon every occasion he was out-generalled by Lee. The first period of the summer's fighting began on 5th May 1864, and lasted until 3rd June. It was marked by the terrible battles of the Wilderness, Spottsylvania, and Cold Harbor, in the course of which Grant lost more than 60,000 men killed and wounded without making any perceptible advance towards the object of the campaign. In one of his despatches in May he had said, "I propose to fight it out on this line if it takes all summer," but after his bloody repulse at Cold Harbor, 3rd June, he abandoned that line and chose a different method of circumventing Lee and approaching Richmond. He did what M'Clellan was on the point of doing two years before when he was overruled by Halleck. He crossed the James river and moved upon Petersburg, a point from which he might hope to cut Lee's communications with points to the southward. But this movement was only partially successful; the Confederates succeeded in reaching Petersburg first, and the affair settled down into a siege which lasted both summer and winter. Meanwhile the ground was being cut from under Lee's feet. In a masterly campaign Sherman pushed Johnston back upon Atlanta. Jefferson Davis superseded Johnston by Hood, a general who believed in hard blows, and soon received some at Sherman's hands. The result was the fall of Atlanta. Hood then made a dash towards Tennessee, hoping to draw Sherman after him, but the force of the latter was sufficiently large to allow of his dividing it. He took 60,000 men with him on a march to the seaboard, there to obtain a new base from which to move to the assistance of Grant. The success of this sweeping movement was entirely dependent upon the crushing of Hood when the latter should invade Tennessee. This work was entrusted to General Thomas, who was left with about 20,000 men, while as many more were summoned from different quarters to reinforce him. On the 15th and 16th of December, in a masterly battle before Nashville, perhaps the most brilliant action of the war, Thomas completely annihilated the army of Hood. A few days later Sherman reached Savannah, and began from that point his northward march against Lee. The Confederates gathered a remnant of about 20,000 men to oppose him, the command being once more entrusted to the sagacious Johnston. In an exciting display of strategy Johnston was driven north-

wards before Sherman until the northern portion of North Carolina was reached. For a moment it seemed that the armies of Johnston and Lee would coalesce, only to be crushed between Grant and Sherman as the upper and the nether millstones, but this was prevented by Sheridan's brilliant victory at Five Forks, which turned Lee's right wing and cut off his southward retreat. Weight of numbers on the northern side at length became irresistible; Grant, with 100,000 men, broke through Lee's centre at Petersburg, the Confederate Government abandoned Richmond, and in a few days Lee surrendered the remnant of his army at Appomattox Courthouse. A few days later Johnston surrendered his army to Sherman, and the great Civil War was over.

After the assassination of President Lincoln a disposition was shown by his successor, Andrew Johnson, to deal severely with the Confederate leaders, and it was understood that indictments for treason were to be brought against General Lee and others. Grant nipped these proceedings in the bud by insisting that the United States Government was bound by the terms which he had accorded to Lee and his army at Appomattox. He went so far as to threaten to resign his commission if the President disregarded his protest. This energetic action on Grant's part saved the United States from a foul stain upon its escutcheon. In the summer of 1866 the grade of general was created, and Grant was promoted to that position. In the course of the following year he became involved in the deadly quarrel between President Johnson and Congress. In order to tie the President's hands Congress had passed the Tenure of Office Act, forbidding the President to remove any cabinet officer without the consent of the Senate; but in August 1867 President Johnson suspended Secretary Stanton and appointed Grant secretary of war *ad interim* until the pleasure of the Senate should be ascertained. Grant accepted the appointment under protest, and held it until the following January, when the Senate refused to confirm the President's action, and Secretary Stanton resumed his office. President Johnson was much disgusted at the readiness with which Grant turned over the office to Stanton, and a bitter controversy ensued between Johnson and Grant. Hitherto Grant had taken but little part in politics. The only vote which he had ever cast for President was in 1856 for James Buchanan; and sundry leading Democrats, so late as the beginning of 1868, hoped to make him their candidate in the election of 1868; but the effect of the controversy with President Johnson was to bring Grant forward most conspicuously as the candidate of the Republican party. At the convention in Chicago, 20th May 1868, he was unanimously nominated on the first ballot. The Democratic party soon afterwards did all in its power to help his election by nominating as his competitor the one Democrat in the United States who had the smallest chance of beating him—Horatio Seymour, lately governor of New York, an excellent statesman, but at that time quite hopeless as a candidate because of his attitude during the war. The result of the contest was at no time in doubt; Grant received 214 electoral votes, and Seymour 80.

Presidency, 1868.

The most important domestic event of Grant's first term as President was the adoption of the fifteenth amendment to the Constitution, 30th March 1870, guaranteeing the right of suffrage throughout the United States without regard to race, colour, or previous condition of servitude. The most important event in foreign policy was the treaty with Great Britain of 8th May 1871, commonly known as the Treaty of Washington, whereby several controversies between the United States and Great Britain, including the bitter questions as to damage inflicted upon the United States by the *Alabama* and other Confederate cruisers built and equipped in England, were amicably referred to arbitration. In 1869 the Government of San Domingo expressed a wish for the annexation of that island by the United States, and such a step was favoured by Grant, but it failed to obtain the requisite two-thirds vote in the Senate. In May 1872 something was done towards alleviating the odious Reconstruction laws for dragooning the South, which had been passed by Congress in spite of the vetos of President Johnson. The Amnesty Bill restored civil rights to all persons in the South, save some 350 who had held high positions under the Confederacy. As early as 1870 President Grant recommended measures of civil service reform, and succeeded in obtaining an Act authorizing him to appoint a Civil Service Commission, and to prescribe rules for its proceedings. A commission was accordingly created, but owing to the persistent hostility of the politicians in Congress it accomplished but little. The need for such civil service reform was beginning to be sorely felt by the country. During the fifty years since Crawford's Tenure of Office Act was passed in 1820, the country had been growing more and more familiar with the spectacle of corruption in high places. The evil rose to alarming proportions during Grant's Presidency, partly because of the immense extension of the civil service, partly because of the growing tendency to alliance between spoilsmen and the persons benefited by protective tariffs, and partly because the public attention was still so much absorbed in Southern affairs that little energy was left for curbing rascality in the North. The scandals, indeed, were rife in Washington, and affected persons who were in close relations with the President, so that evil-minded persons were inclined to suspect him of complicity with the rogues. President Grant was ill fitted for coping with the difficulties of such a situation. Along with high intellectual powers in certain directions, he had a simplicity of nature quite charming in itself, but often calculated to render him the easy prey of sharpers. He found it almost impossible to believe that anything could be wrong in persons to whom he had given his friendship, and on several occasions such friends proved themselves unworthy of him. The feeling was widely prevalent in the spring of 1872 that the interests of pure government in the United States demanded that President Grant should not be elected to a second term. This feeling led a number of high-minded gentlemen to form themselves into an organization under the name of Liberal Republicans. They held a convention at Cincinnati in May with the intention of nominating for the Presidency Charles Francis Adams, who had so ably represented the United States at the Court of St James's during the Civil War. The convention, was, however, captured by politicians who converted the whole affair into a farce by nominating Horace Greeley, editor of the *New York Tribune*, who represented almost anything rather than the object for which the convention had been called together. The Democrats had been awaiting the action of this convention; they despaired of electing a candidate of their own, and hoped to achieve success by adopting the Cincinnati nominee, should he prove to be an eligible person. The event showed that while their defeat in 1868 had taught them despondency, it had not taught them wisdom; it was still in their power to make a gallant fight by nominating a person for whom Republican reformers could vote. But with almost incredible fatuity, they held a convention and adopted Greeley as their candidate. As a natural result Grant was re-elected by an overwhelming majority.

Re-elected, 1872.

The most important event of his second term was his

veto of the Inflation Bill in 1874, followed by the passage of the Resumption Act in the following year. The country was still labouring under the curse of an inconvertible paper currency created by the Legal Tender Act of 1862. There was a considerable party in favour of debasing the currency indefinitely by inflation, and a Bill with that object in view was passed by Congress in April 1874. It was promptly vetoed by President Grant, and two months later he wrote a very sensible letter to Senator Jones of Nevada advocating a speedy return to specie payments. The passage of the Resumption Act in January 1875 was largely due to his consistent advocacy, and for these measures he surely deserves as high credit as for any of his victories in the field. In spite of these great services, popular dissatisfaction with the Republican party rapidly increased during the years 1874–76. The causes were twofold: firstly, there was great dissatisfaction with the troubles in the Southern states, owing to the harsh Reconstruction laws and the robberies committed by the carpet-bag governments which those laws kept in power; secondly, the scandals at Washington, comprising wholesale frauds upon the public revenue, awakened lively disgust. In some cases the culprits were so near to President Grant that many persons found it difficult to avoid the suspicion that he was himself implicated, and never perhaps was his hold upon popular favour so slight as in the summer and autumn of 1876.

Later life.

After the close of his Presidency in the spring of 1877 Grant started on a journey round the world, accompanied by his wife and one son. He was received with distinguished honours in England and on the continent of Europe, whence he made his way to India, China, and Japan. After his return to America he went back to his old home in Galena, Illinois. A faction among the managers of the Republican party attempted to secure his nomination for a third term as President, and in the convention at Chicago in June 1880 he received a vote exceeding 300 during 36 consecutive ballots. Nevertheless, his opponents made such effective use of the popular prejudice against third terms that the scheme was defeated, and Garfield was named in his stead. In August 1881 General Grant bought a house in the city of New York. His income was insufficient for the proper support of his family, and accordingly he had become partner in a banking house in which one of his sons was interested along with other persons. The name of the firm was Grant and Ward. The ex-President invested in it all his available property, but paid no attention to the management of the business. His facility in giving his confidence to unworthy people was now to be visited with dire calamity. In 1884 the firm became bankrupt, and it was discovered that two of the partners had been perpetrating systematic and gigantic frauds. This severe blow left General Grant quite penniless, just at the time when he was beginning to suffer acutely from the disease which finally carried him off. Down to this time he had never made any pretensions to literary skill or talent, and had never regarded himself in the light of an author; but on being approached by the *Century Magazine* with a request for some articles, he undertook the work in order to keep the wolf from the door. It proved a congenial task, and led to the writing of his *Personal Memoirs*, a frank, modest, and charming book, which ranks among the best standard military biographies. The sales earned for the general and his family something like half a million dollars. The circumstances in which it was written made it an act of heroism comparable with any that Grant ever showed as a soldier. During most of the time he was suffering tortures from cancer in the throat, and it was only four days before his death that he finished the manuscript. In the spring of 1885 Congress passed a Bill creating him a general on the retired list; and in the summer he was removed to a cottage at Mount M'Gregor, near Saratoga, where he passed the last five weeks of his life, and where he died on the 23rd of July 1885. His mortal remains were deposited in a tomb in Riverside Park, in New York City, overlooking the Hudson river.

Character.

As a soldier Grant possessed very high qualities; the combination of self-reliant courage, fertility of resource, and swiftness in action was perhaps never more perfectly realized than in his wonderful campaign in the rear of Vicksburg. He was invariably patient and equable in temper in the most trying circumstances, neither elated by success nor cast down by ill-fortune. For dogged persistency he has never been surpassed. He possessed, in a high degree, that quick and subtle appreciation of topography which is essential to success in great military operations. Though he was slow and deliberate in conversation and in the ordinary movements of his body, his thoughts moved nimbly and his military actions were marked by promptness. Yet, in spite of Vicksburg, one can hardly accord him a place in the first rank of military commanders. He never rose to the grade of Napoleon or Frederick, although in some of his movements we can see Napoleonic touches. When he was pitted against Lee, in the last year of his military life, there could be no doubt as to the superior genius of the Confederate general. In character Grant showed many admirable and lovable traits. There was a charming side to that trustful simplicity, which was at times almost like that of a sailor set ashore. He abounded in kindliness and generosity, and if there was anything especially difficult for him to endure, it was the sight of human suffering, as was shown on the night at Shiloh, where he lay out of doors in an icy rain rather than stay in a comfortable room where the surgeons were at work. His good sense was strong, as well as his sense of justice, and these qualities stood him in good service as President, especially in his triumphant fight against the greenback monster. Altogether, in spite of some shortcomings, Grant was a massive, noble, and lovable personality, well fit to be remembered as one of the heroes of a great nation.

(J. Fi.)

Grantham, a municipal borough, incorporated in the 15th century (extended 1879), parliamentary borough (now returning only one member), and market-town of Lincolnshire, England, on the Witham, 105 miles north of London by rail. Area of municipal borough, 1677 acres. Population (1881), 16,886; (1901), 17,593.

Granville, a seaport and bathing resort in the arrondissement of Avranches, department of Manche, France, with terminal station on railway, 204 miles from Paris. Granville ranks next to Bordeaux as a market for cod-fish from Newfoundland. The total number of vessels (not including those engaged in coasting trade) entered and cleared in 1899 was, respectively, 252 of 43,416 tons, and 260 of 48,160 tons. Population (1881), 9693; (1891), 10,373; (1901), 11,667. In the commune are included the Chausey Islands, which lie 7 miles to the W.N.W. of Granville. They are a group of 52 islands, extending east and west for a length of 7 miles, and north and south for 5 miles,

but only Grande (100) is inhabited. It has a fort, lighthouse, and semaphore, and there are important granite quarries.

Granville, George Leveson-Gower, 2nd Earl (1815–1891), English statesman, eldest son of the 1st Earl (1773–1846), the friend of Canning and ambassador at Paris (1824–41), was born in London, 11th May 1815. After being at Eton and Christ Church, he was at Paris as attaché under his father, until, in 1836, he was returned to Parliament in the Whig interest for Morpeth. For a short time at the end of Melbourne's Ministry he was Under-Secretary for Foreign Affairs. From 1841 until his father's death in 1846 he sat for Lichfield. In the House of Lords he signalized himself as a Free Trader, but he was regarded as a courtly wit and a dandy rather than as a serious politician, and Lord John Russell made him Master of the Buckhounds (1846). He was made Vice-President of the Board of Trade in 1848, and in December 1851 succeeded Palmerston at the Foreign Office for a short time; in 1853 he became President of the Council. He took a prominent part in the promotion of the Exhibition of 1851 abroad, especially at Paris, and won golden opinions from the French. From 1855 Granville led the Liberals in the Upper House, and in June 1859 Queen Victoria, embarrassed by the rival ambitions of Palmerston and Russell, sent for him to form a Ministry, but Russell preferred to serve under Palmerston, and Granville was quite content to be President of the Council; in 1866 he retired with the Ministry, having meantime been appointed Lord Warden of the Cinque Ports. In December 1868 he became Colonial Secretary in Gladstone's first administration. His tact was invaluable to the Government in carrying the Irish Church and Land Bills through the House of Lords. On 27th June 1870, upon the death of Lord Clarendon, he was transferred to the Foreign Office. As Foreign Minister (1870–74 and 1880–85) Lord Granville was amiable but weak, and his periods of office were marked by a good deal of nerveless diplomacy, for which Great Britain both then and since had to pay dear. The Franco-German war of 1870 broke out within a few days of his pronouncement that not a cloud obscured the political horizon. Russia took advantage of the situation to denounce the Black Sea clauses of the Treaty of Paris (1856), Lord Granville's protest being entirely reasonable but quite ineffectual. In 1871 an intermediate zone was described by Granville and Gortchakoff between Russia and Afghanistan. When, however, in 1873, Russia took permanent possession of Khiva (within the neutral zone), Granville had to accept Schuvaloff's "assurances" that the advance was temporary. The Conservatives came back to power in 1874, and Granville's part for the next six years was to criticize Disraeli's "spirited" foreign policy, a task which he performed with much graceful irony, and to defend his own more pliant methods. He returned to the Foreign Office in 1880, but his policy remained an ineffectual one. In 1883–84 he was severely rebuffed by Bismarck over the Angra-Pequeña question. With a mind as open as Gladstone's to the reception, even in old age, of entirely new ideas, Granville adhered to his chief in the question of Home Rule (1886), and gave way with his accustomed grace to Lord Rosebery when the latter was preferred to the Foreign Office. He took charge of the Colonial Office (February–July 1886) for his remaining six months of office, though he was far from being *persona grata* in the colonies; and he retired from public life in the summer of 1886. He died in South Audley Street, London, on 31st March 1891. Lord Granville was an admirable after-dinner speaker and one of the most charming talkers. He spoke French like a Parisian, but with a slight Court accent recalling the *ancien régime*. He was a master of the art of diplomatic fencing and word-play, but he had no grasp of the really important problems which were gradually coming to the front in the British Empire.

Graslitz, a town in the north-west of Bohemia (Austria), near the Saxon frontier. It has a station on the Falkenau and Buschtiehrader railways. One of the most important industrial centres of Bohemia, its specialties are the manufacture of musical instruments, carried on both as a factory and domestic industry, and lace-making. Next in importance is cotton-spinning and weaving, machine embroidery, &c., and the mother-of-pearl industry. Graslitz, which is distinguished by its strong German-Nationalist sentiment, was the scene of some violent demonstrations in 1899, which were accompanied by loss of life. Population, all German (1900), 11,803.

Grasse, chief town of arrondissement, department of Alpes Maritimes, France, 30 miles W.S.W. of Nice by rail. About 2,000,000 ℔ of roses and 4,000,000 ℔ of orange flowers are annually produced for the distillation of essences. There are also important manufactures of olive and sweet almond oil. Population (1881), 7597; (1901), 15,429.

Gratz, or Graz, capital of the Austrian crownland of Styria. It possesses a number of interesting public monuments, two bridges, a new synagogue, a technical college, a new university building, a town hall (1892), a large new museum (1895), a court of justice, &c. The university is attended by about 1550 students, including Italians from the Küstenland and Dalmatia. The polytechnic is attended by nearly 400 students. There are four gymnasia, two realschule, and five other technical and special high schools. Not only trade, but also industry, has made great progress in consequence of increased railway facilities and the establishment in the town of the extensive workshops of the Southern Railway. Its manufactures now include rails, machinery, bicycles, &c., and all kinds of iron and steel goods; paper, perfumes, leather and leather goods; sugar, soap, chemicals, physical and optical instruments; and pottery, champagne, beer, flour, and artistic printing and lithography, &c. Gratz played a prominent part in the German national agitation under the Badeni and Thun ministries, and was the scene of violent demonstrations against the Government, which were repressed with loss of life. The progress of Socialism among the working classes has been as marked among the labourers as that of the Pan-Germanic sentiment among the other sections of the community. The "Emancipation from Rome" movement also aroused a strong echo in Gratz, particularly among the students. Population, almost wholly German and Roman Catholic (1890), 112,069; (1900), 138,270.

Graudenz, a town of Prussia, province of West Prussia, on the right bank of the Vistula, 37 miles by rail north by east from Thorn. It is a place of considerable manufacturing activity, especially in carriages and carpets, though there are also iron-foundries, flour-mills, breweries, and brick-works, a large trade in corn, cattle, horses, timber, and wool. The town possesses a museum, and a monument (1815) to Courbière, the defender of the town in 1807. Graudenz is an important place in the German system of fortifications, belonging to the cluster of forts on the eastern frontier. Population (1885), 17,336; (1900), 32,800.

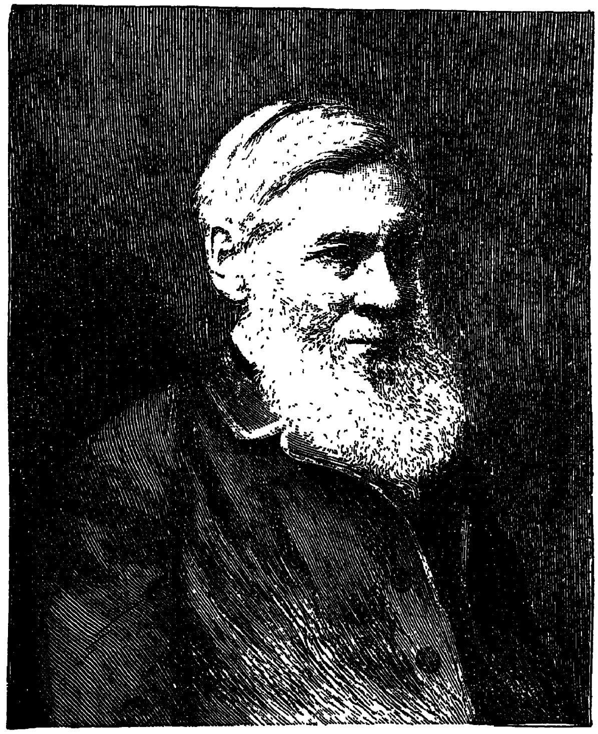
Gravelines, a town in the arrondissement of Dunkirk, department of Nord, France, 48 miles N.W. of Lille, with station on railway from Calais to Dunkirk. It is a centre for the cod and herring fisheries, and fish-salting and flax- and hemp-spinning are amongst its industries. The situation of the port is one of the best in

France on the North Sea. The harbour has an area of 75 acres; depth at entrance 18 and 16 feet, high spring and neap tides; the Government wet dock covers 6 acres, and has 1968 feet of quayage; a channel $1\frac{5}{8}$ mile long connects with the sea, and inland there is communication with the northern network of canals. In 1899, 162 vessels of 21,680 tons entered, and 164 of 21,846 tons cleared. The total tonnage of river traffic on the Aa amounted to 88,416 tons in 1900. The export trade is mainly with England. Population (1881), 3902; (1901), 6202.

Gravesend, a municipal and parliamentary borough of Kent, England, on the Thames, 22 miles east by south of London by rail. Gravesend belongs to the port of London. The hospital has been extended. There is a college for daughters of Congregational ministers, and an industrial school for boys. Recent erections are a technical school containing a public library, a public hall, and a sanatorium at Cobham. The town pier has been acquired by the Tilbury Railway Company. Area of municipal borough, 1256 acres. Population (1881), 23,302; (1901), 27,175.

Gray, Asa (1810–1888), American botanist, was born at Paris, Oneida county, N.Y., on 18th November 1810. He was the son of a farmer, and received no formal education except at a small rural academy and a provincial medical school. From the professor of chemistry and *materia medica* in the latter he obtained his first instruction in science (1825–26). In the spring of 1827 he first began to collect and identify plants. His formal education, such as it was, ended in February 1831, when he took the degree of Doctor of Medicine. His first contribution to descriptive botany appeared in 1835, and thereafter an uninterrupted series of contributions to systematic botany flowed from his pen for fifty-three years. In 1836 his first botanical text-book appeared under the title *Elements of Botany*, followed in 1839 by his *Botanical Text-Book for Colleges, Schools, and Private Students.* This text-book developed into his *Structural Botany*, written with a view to interest large numbers of readers. He published later the following smaller books: *First Lessons in Botany and Vegetable Physiology*, 1857; *How Plants Grow*, 1858; *Field, Forest, and Garden Botany*, 1869; *Botany for Young People, Part II., How Plants Behave*, 1872. These books served the purpose of developing popular interest in botanical studies. His most important contribution, however, was his *Manual of the Botany of the Northern United States*, the first edition of which appeared in 1847. This manual has passed through a large number of editions, is clear, accurate, and compact to an extraordinary degree, and within its geographical limits is an indispensable book for the student of American botany.

Throughout his life Dr Gray was a diligent writer of reviews of books on natural history subjects. Often these reviews were elaborate essays, for which the books served merely as texts; often they were clear and just summaries of extensive works; sometimes they were sharply critical, though never ill-natured or unfair; always they were interesting, lively, and of literary as well as scientific excellence. The greater part of Dr Gray's strictly scientific labour was devoted to a flora of North America, the plan of which originated with his early teacher and associate, Dr John Torrey of New York. The second volume of Torrey and Gray's *Flora* was completed in 1843; but for forty years thereafter Dr Gray gave up a large part of his time to the preparation of his *Synoptical Flora*, the first part of which did not appear till 1878. He lived at the precise period when the flora of North America was being discovered, described, and systematized; and his enthusiastic labours in this fresh field placed him at the head of American botanists and on a level with the most famous botanists of the world. In 1856 he published a paper on the distribution of plants under the title *Statistics of the Flora of the Northern United States;* and this paper was followed in 1859 by a memoir on the botany of Japan and its relations to that of North America, a paper of which Sir J. D. Hooker said that "in point of originality and far-reaching results [it] was its author's *opus magnum.*" It was Gray's study of plant



Asa Gray.

distribution which led to his intimate correspondence with Charles Darwin during the years in which Darwin was elaborating the doctrines that later became known as Darwinism. From 1855 to 1875 Dr Gray was both a keen critic and a sympathetic exponent of the Darwinian principles. His influence on this subject, both in the United States and in England, was due to the candour, clearness, and conservatism of his expositions. Dr Gray's religious views were those of the Evangelical bodies in the Protestant Church; so that, when Darwinism was attacked as equivalent to atheism, he was in position to answer effectively the unfounded allegation that it was fatal to the doctrine of Design. He taught that "the most puzzling things of all to the old-school teleologists are the *principia* of the Darwinian." He openly avowed his conviction that the present species are not special creations, but rather derived from previously existing species; and he made his avowal with frank courage, when this truth was scarcely recognized by any naturalists, and when to the clerical mind evolution meant atheism.

In 1842 Dr Gray accepted the Fisher professorship of natural history in Harvard University. On his accession to this chair the university had no herbarium, no botanical library, few plants of any value, and but a small garden, which for lack of money had never been well stocked or well arranged. Dr Gray soon brought together, chiefly by widespread exchanges, a valuable herbarium and library, and arranged the garden; and thereafter the development of these botanical resources was part of his regular labours. The herbarium soon became the largest

and most valuable in America, and on account of the numerous type specimens it contains it is likely to remain a collection of national importance. Nothing of what Dr Gray did for the botanical department of the university has been lost; on the contrary, his labours were so well directed that everything he originated and developed has been enlarged, improved, and placed on stable foundations. He himself made large contributions to the establishment by giving it all his own specimens, many books, and no little money, and by his will he gave it the royalties on his books. During his long connexion with the university he brought up two generations of botanists, who are now scattered all over the United States. The Gray Herbarium was for years the resort of nearly all the working botanists now in influential positions, and Dr Gray always took a strong personal interest in the researches and the personal prospects of the young men who studied under his eyes. His scientific life was mainly spent in the herbarium and garden in Cambridge; but his labours there were relieved by numerous journeys to different parts of the United States and to Europe, all of which contributed to his work on the Synoptical Flora. Every journey enlarged his experience, increased his resources, and added to his reputation. He lived to a good age—long enough, indeed, to receive from learned societies at home and abroad abundant evidence of their profound respect for his attainments and services. He died at Cambridge, Mass., 30th January 1888. (C. W. E.)

Grays Thurrock, a town and parish in the South-Eastern parliamentary division of Essex, England, on the Thames, 3 miles north-west of Tilbury Fort by rail. There are an endowed and two training-ship schools. Drainage works costing over £40,000 were completed in 1894. The buildings include a public hall and a free library (1894). The town does trade in bricks, lime, and cement. Area of urban district, 1382 acres. Population (1881), 5327; (1901), 13,831.

Great Barrington, a town of Berkshire county, Massachusetts, U.S.A., on the river Housatonic in the Berkshire Hills. It is traversed by a branch of the New York, New Haven, and Hartford Railway, and is well known as a summer resort. Population (1890), 4612; (1900), 5854, of whom 1187 were foreign-born and 138 negroes.

Great Britain. See BRITISH EMPIRE, ENGLAND AND WALES, ENGLISH HISTORY, SCOTLAND, UNITED KINGDOM.

Great Falls, capital of Cascade county, Montana, U.S.A., in 47° 30′ N. and 111° 17′ W., on the south bank of the Missouri river, opposite the mouth of Sun River, at an altitude of 3331 feet. It is near the great falls of the Missouri, from which it derives its name. It is on a branch line of the Great Northern Railway, and is the terminus of the Great Falls and Canada Railway, and of a branch line into the mountains to the south. It is a well-built city, founded in 1867. It has smelters for the treatment of silver, lead, and copper ores. Population (1890), 3979; (1900), 14,930, of whom 4692 were foreign-born and 128 negroes.

Great Salt Lake, a large body of water without outlet, in Utah, U.S.A. It lies at the western base of the Wasatch range, from which it receives numerous streams, the principal of which are the rivers Jordan, Weber, and Bear. The inflow to the lake is variable in amount, owing to irregularity in rainfall, and as the only means of discharge—evaporation—is quite uniform, the level of the lake has oscillated greatly in past times, while in recent years, owing to the fact that much of the water of its tributaries has been used for irrigation, the lake level has been considerably lowered. The lake being shallow and its shores quite level, especially on the west, a slight reduction in the water level causes a notable diminution in area. The lake is some 80 miles in length north and south, and on an average 40 miles in breadth. The water contains about 20 per cent. by weight of solid matter, mainly chloride of sodium. The country to the east and south of the lake is well settled by Mormons, and is highly cultivated, while that on the north and west, since it possesses no water for irrigation, is a desert.

Great Slave Lake (ATHAPUSCOW), a lake of Mackenzie district, Canada. It is situated between 60° 50′ and 62° 55′ N. lat. and 108° 40′ and 117° W. long., at an altitude of 520 feet above the sea. It is 325 miles long, from 15 to 65 miles wide, and includes an area of 9770 square miles. Its coast-line is very irregular and deeply indented by large bays, and its northern shores are rugged and mountainous. The Yellow-knife, Hoar-frost, Lockhart, discharging the waters of Clinton-Colden and Artillery lakes, the Tchzudezeth, Du Rocher, Hay, and Slave rivers—the last a continuation of the Mackenzie—empty into Great Slave Lake. It is navigable from about 1st July to the end of October. It was discovered in 1771 by Samuel Hearne.

Greathead, James Henry (1844–1896), British engineer, was born at Grahamstown, Cape Colony, on 6th August 1844. He migrated to England in 1859, and in 1864 was a pupil of P. W. Barlow, from whom he became acquainted with the shield system of tunnelling with which his name is especially associated. Barlow, indeed, had a strong belief in the shield, and was the author of a scheme for facilitating the traffic of London by the construction of underground railways running in cast-iron tubes constructed by its aid. To show what the method could do, it was resolved to make a subway under the Thames near the Tower, but the troubles encountered by Brunel in the Thames Tunnel, where also a shield was employed, made engineers hesitate to undertake the subway, even though it was of very much smaller dimensions (6 feet 7 inches internal diameter) than the tunnel. At this juncture Greathead came forward and offered to take up the contract; and he successfully carried it through in 1869 without finding any necessity to resort to the use of compressed air, which Barlow in 1867 had suggested might be employed in water-bearing strata. After this he began to practise on his own account, and mainly divided his time between railway construction and taking out patents for improvements in his shield, and for other inventions such as the "Ejector" hydrant (see POWER TRANSMISSION, HYDRAULIC). Early in the 'eighties he began to work in conjunction with a company whose aim was to introduce into London from America the Hallidie system of cable traction, and in 1884 an Act of Parliament was obtained authorizing what is now the City and South London Railway—a tube-railway to be worked by cables. This was begun in 1886, and the tunnels were driven by means of the Greathead shield, compressed air being used at those points where water-bearing gravel was encountered. During the progress of the works electrical traction became so far developed as to be superior to cables; the idea of using the latter was therefore abandoned, and when the railway was opened in 1889 it was as an electrical one. In 1888 Greathead became engineer, together with Sir Douglas Fox, to the Liverpool Overhead Electric Railway, and afterwards was engaged in two other important underground lines in London—the Waterloo and City, and the Central London. He lived to see the tunnels of the former completed under the river, but the latter was scarcely begun at the time of his death, which happened at Streatham, in the south of London, on 21st October 1896.

GREECE.

Geography and Statistics.

GREECE has undergone many vicissitudes in recent years. The natural and excusable desire of the Greeks to bring about the political union of their race has exposed the country to paroxysms of excitement at each successive crisis in the Eastern Question; a series of costly mobilizations has ruined the national finances, and repeated warlike movements have culminated in a disastrous conflict. Meanwhile the vital interests of the country have been neglected by reckless politicians, bent on acquiring popularity by flattering the national sentiment; urgent reforms have been postponed or abandoned, the administrative and judicial systems have been demoralized by party influences, and public order has not always been efficiently maintained. Notwithstanding these serious drawbacks, Greece has made sensible progress since 1870: commerce has advanced rapidly, agriculture and other industries by slow degrees, education is widely diffused, and though the State is bankrupt, the great mass of the people is well-to-do, if not rich. Owing to the tact and sagacity of King George, the country, amid all the vicissitudes of its recent history, has escaped revolution, and the dynasty may be regarded as firmly established. The acquisition of the fertile province of Thessaly will in course of time add greatly to the resources of the kingdom. The interest of Greece to the scholar, the antiquary, and the student of art has, if possible, been enhanced by recent discoveries, and the peculiar charm of its scenery has received wider appreciation. With improved communications and complete tranquillity in the interior, there will be a constant increase in the number of those who visit this beautiful and interesting country, which may derive no slight material profit from its historic and natural attractions.

No State survey of Greece has ever been undertaken. The area of the country, according to the official figures, was 47,516 square kilometres before the acquisition of the Ionian Islands in 1864, 50,211 square kil. prior to the annexation of Thessaly and part of Epirus in 1881, and 63,606 square kil. in 1896. If we deduct 395 square kil., the extent of territory ceded to Turkey after the war of 1897, the present area of Greece would be 63,211 square kil. Other authorities give 65,194 and 65,119 square kil. as the area prior to the rectification of the frontier in 1898. The population in 1889 was 2,187,208, or 34·38 to the square kil., the population of the territories annexed in 1881 being approximately 350,000; and in 1896, 2,433,806, or 38·26 to the square kil. (according to the official estimate of the area), showing an increase of 246,598, or 1·61 per cent. per annum. The population by sex in 1896 is given as 1,266,816 males and 1,166,990 females. This proportion (52 per cent. males to 48 females) corresponds to that found in Italy, Servia, and Bulgaria. The preponderance of males is most marked in the maritime districts, and in the departments of Larissa and Trikkala. Only in the department of Laconia, in the Cyclades, and in Cephalonia is the female population in excess of the male. Neither the census of 1896 nor that of 1889 gives any classification by professions, religion, or language, but the following figures are derived from unofficial sources:—agricultural and pastoral employments, 444,096; industries, 64,211; traders and their employees, 117,979; labourers and servants, 31,321; various professions, 15,735; officials, 12,109; clergy, 10,059; national defence, 34,624. In 1879, 1,635,698 of the population were returned as Orthodox Christians, 14,677 as Catholics, 2652 as Jews, and 740 as of other religions. The annexation of Thessaly and part of Epirus is stated to have added 24,165 Mahommedan subjects to the Hellenic kingdom. A considerable portion of these, however, emigrated immediately after the annexation, and although a certain number subsequently returned, the total Mahommedan population in Greece is estimated to be under 20,000. The Albanian population still probably exceeds 120,000. It is gradually being absorbed in the Hellenic population. The Vlach population was increased by the annexation of Thessaly; several thousands of these nomad shepherds are to be found in the Pindus range; the greater proportion speak Greek as well as a dialect of Rumanian. By a law of 27th November 1899 Greece, which had hitherto been divided into 16 departments (νομοί) was re-divided into 26 departments, as follows:—

Area and population.

Departments.	Population according to Census of 1896.	Departments.	Population according to Census of 1896.
1. Attica	255,978	15. Arcadia	167,092
2. Bœotia	57,091	16. Achaia	144,826
3. Phthiotis	98,764	17. Elis	91,425
4. Phocis	60,472	18. Triphylia	86,471
5. Acarnania	126,892	19. Messenia	119,327
6. Euritania	43,667	20. Laconia	62,839
7. Arta	39,144	21. Lacedæmon	84,929
8. Trikkala	96,007	22. Corfu	94,686
9. Karditsa	80,766	23. Cephalonia	70,077
10. Larissa	86,513	24. Leukas (with Ithaca)	43,173
11. Magnesia	91,828		
12. Eubœa	106,777	25. Zante	45,032
13. Argolis	80,695	26. Cyclades	134,747
14. Corinth	64,577		

The population is densest in the Ionian Islands, exceeding 286 per square mile. The departments of Acarnania, Phocis, and Eubœa are the most thinly inhabited (about 54, 57, and 62 per square mile respectively).

The movement of the population since 1881 was as follows:—

Year.	Births.	Deaths.	Marriages.	Excess of Births.
1882	43,157	32,194	11,186	10,963
1883	43,061	34,619	11,615	8,442
1884	57,995	35,899	13,657	22,096
1889	74,666	53,512	18,558	21,154
1890	78,226	55,813	19,899	22,443

Both the birth-rate and death-rate are low, being 27·6 and 20·7 per 1000 respectively. Infant mortality is slight, and in point of longevity Greece compares favourably with most other European countries. The number of illegitimate births is 12·25 per 1000. Of the total population 22·3 per cent. live in towns. The population of the principal towns is:—

	1889.	1896.		1889.	1896.
Athens	107,251	111,486	Volo	11,029	16,788
Piræus	34,327	43,848	Larissa	13,610	15,373
Patras	33,529	37,985	Zante	16,608	14,906
Trikkala	14,820	21,149	Kalamata	10,696	14,298
Hermopolis (Syra)	22,104	18,760	Pyrgos	12,647	12,708
Corfu	19,025	18,581	Tripolis	10,698	10,465

No trustworthy information is obtainable with regard to immigration and emigration. In 1889 it was computed that there were 135,466 native-born Greeks in foreign lands, but this figure is probably too low. Every year numbers of young men emigrate to the United States from Arcadia, Laconia, and Maina; there has been a considerable emigration to Egypt from the Cyclades. There is an increasing immigration into the towns from the mountainous districts.

In the higher departments of the administration no important changes have been effected in recent years. In 1898 the number of deputies in the Boulé was increased from 207 to 234. Some years previously, a law diminishing the national representation and enlarging the constituencies was passed by Trikoupis, with the object of checking the local influence of electors upon deputies, but the measure was subsequently repealed. The practice of bartering personal favours, known as συναλλαγή, still continues, to the great detriment of public morality. Local administration is in the hands of some 20,000 officials, most of them inadequately remunerated and liable to removal upon a change of Government. A proletariat of office-seekers has thus been created, and large numbers of well-educated persons spend many years in idleness or in political agitation. The administration of justice suffers under the existing system, more especially in the country districts, where the judges, most of whom are removable, must reckon with the influential politicians and their adherents. The pardon or release of a convicted criminal is not infrequently due to pressure on the part of some powerful patron. In the circumstances crime is less rife than might be expected. A serious feature is the great prevalence of homicide, due in part to the passionate character of the people, but still more to the almost universal practice of carrying weapons. The traditions of the vendetta are almost extinct in the Ionian Islands, but still linger in Maina, where family feuds are transmitted from generation to generation. The brigand of the old-fashioned type (λῃστής, κλεφτής) has almost disappeared, except in the remoter country districts, and piracy has been practically suppressed, but numbers of outlaws (φυγόδικοι) still haunt the mountains, and the efforts of the police to bring them to justice are far from successful. Their ranks were considerably increased after the war of 1897, when many deserters from the army and adventurers who came to Greece as volunteers betook themselves to a predatory life. On the other hand, there is no habitually criminal class in Greece, such as exists in the large centres of civilization. Professional mendicancy is still rare. The system of employing officers and soldiers of the regular army for police duties has proved unsatisfactory, and will soon be abolished. Prison discipline and sanitation are very deficient; conflicts among the prisoners are sometimes reported, in which knives and even revolvers are employed. A good prison has been built near Athens by Andreas Syngros, the national benefactor. The Greeks, like the other nations liberated from Turkish rule, are somewhat litigious, and numbers of lawyers find occupation even in the smaller country towns. A new civil code, based on Saxon and Italian law, has been drawn up by a commission of jurists. A court of appeal (at Larissa) has been added to the four already existing; there are now 22 courts of first instance and 237 justices of the peace.

Administration and justice.

A complete reorganization of the Greek army has been projected under the auspices of the Crown Prince. The experience of the war of 1897 proved the need of far-reaching administrative changes and disciplinary reforms. The existing organization is based on the laws of 1887 and 1896. Military service is obligatory, and liability to serve begins from the 21st year. The term of service comprises 2 years in the active army, 10 years in the active army reserve (for cavalry 8 years), 8 years in the territorial army (for cavalry 10 years), and 10 years for all branches in the territorial army reserve. As a rule, however, the period of service with the colours is considerably shortened. By a law passed in 1900 the army will consist of 3 divisions, each composed of 2 brigades, and other units to be fixed by royal decree. There are 10 regiments of infantry, each of 2 battalions, and 1 battalion-cadre, in addition to 8 battalions of Euzones or highlanders, and 3 regiments of cavalry, each of 4 squadrons. The infantry are armed with the single-loader Gras (·433″) rifle and a bayonet, the cavalry with a Gras carbine and a sword. The artillery consists of 3 regiments of field artillery of 20 batteries. Two field batteries are armed with 8·7-cm. Krupp guns, the remaining batteries with 7·5-cm. Krupp guns. There is 1 regiment of engineers composed of 2 battalions. The peace strength of the army in 1899 was as follows:—

Defence.

	Officers and Civilians.	Non-commissioned Officers and Men.	Horses and Mules.
War Office	62	...	20
Engineers	101	1,381	158
Artillery	217	2,583	1305
Cavalry	96	1,448	1269
Infantry	873	13,180	452
Ambulance	12	449	51
General services	390	8	86
Military instruction	123	10	180
Gendarmerie	139	4,108	395
Total	2013	23,167	3916

In time of war the total strength is 82,125 officers and men, 14,441 horses and mules, and 180 guns. The kingdom is divided into three military districts, Larissa, Missolonghi, and Athens.

The Greek fleet consists of 5 armour-clad vessels—3 battleships (built 1889–90) of 4885 tons each, and carrying 35 guns, 1 central battery ship (launched 1867), and 1 broadside ship (launched 1869); there are further 1 cruiser, 4 gunboats, 2 coast defence vessels, 29 torpedo boats of various types, 1 torpedo gunboat, 3 torpedo ships, 21 vessels used for various services, and 1 royal yacht. The personnel of the navy is composed of 369 officers and cadets, 917 petty officers, 2134 sailors and stokers, 45 boys, and 387 civilians. The navy is manned chiefly by conscription; the period of service is two years. The Greeks make better sailors than soldiers, and the navy, if reorganized by foreign officers, might be brought to a high state of efficiency.

The Greek branch of the Orthodox Eastern Church is practically autocephalous, like those of Servia, Montenegro, and Rumania, though nominally subject to the Patriarchate of Constantinople. The jurisdiction of the Patriarch was in fact repudiated in 1833, and the severance was completed in 1850. Ecclesiastical affairs are under the control of the Ministry of Education. Church government is vested in the Holy Synod, a council of five ecclesiastics under the presidency of the Metropolitan of Athens; its sittings are attended by a royal commissioner. There are nominally 18 archbishoprics and 22 bishoprics in Greece, but many of the sees are allowed to remain vacant. The number of priests is very large. They belong for the most part to the poorest classes, and, having no fixed stipends, often resort to agriculture or to small trading in order to supplement the scanty fees earned by their ministrations. There are 199 monasteries and 6 nunneries in Greece, with about 1650 monks and 250 nuns. The number of Roman Catholics is probably between 25,000 and 30,000; the majority are in the Cyclades. They have 3 archbishoprics (Athens, Naxos, and Corfu) and 5 bishoprics. There are about 60 Roman Catholic churches. The Greeks, an intelligent people, have always shown a remarkable zeal for learning, and popular education is making great strides. In 1898 there were 2914 "demotic" or primary schools, with 3465 teachers, attended by 129,210 boys (5·38 per cent. of the population) and 29,119 girls (1·19 per cent. of the population). The expenditure on primary schools, which in 1894 was 3,737,620 drachmæ, had risen

Religion and education.

in 1897 to 5,007,440 dr.; the attendance of pupils in the former year was 144,917, in the latter 158,349. In 1898 there were 243 "Hellenic" or secondary schools, with 647 teachers and 13,472 pupils (boys only), maintained by the State at a cost of 1,596,716 dr.; and 40 higher schools or gymnasia, with 291 masters and 3822 pupils, partly maintained by the State (expenditure, 842,640 dr.) and partly by benefactions. The Polytechnic Institute of Athens affords technical instruction in the departments of art and science to 359 students. There are 7 agricultural colleges, 5 theological seminaries, 5 nautical schools, the military college of the Euelpides at Athens, and many private schools. (For the native and foreign archæological institutions, see ATHENS.) The University of Athens in 1899 numbered 57 professors and 2802 students, of whom 815 were from abroad. Of the five faculties theology numbered 55 students, law 1147, medicine 864, arts 289, and pharmacy 121. The university receives a subvention from the State, which in 1899 amounted to 505,040 dr. Higher instruction is practically gratuitous in Greece, and there is a somewhat ominous increase in the number of educated persons who disdain agricultural pursuits and manual labour.

Commerce and industry.

Owing to the natural aptitude of the Greeks for commerce, and their predilection for a seafaring life, a great portion of the trade of the Levant has fallen into their hands. The Greek mercantile marine, which in 1888 consisted of 1352 vessels (70 steamers) with a total tonnage of 219,415 tons, numbered in 1898 1270 vessels (118 steamers) with a total tonnage of 326,041 tons. Almost the whole of the corn trade of Turkey is in Greek hands. A large number of the sailing ships, especially the smaller vessels occupied in the coasting trade, belong to the Heptanesian and Aegean islanders. A considerable portion of the shipping on the Danube and Pruth is owned by the inhabitants of Ithaca and Cephalonia. There are six principal Greek steamship companies, owning 44 steamers with a total tonnage of 27,251 tons. In 1847 there was but one lighthouse in Greek waters; in 1899 there were 110 lighthouses and port-lanterns. Hermopolis (Syra) is the chief seat of the carrying trade, but as a commercial port it yields to Piræus, which is the principal centre of distribution for imports. Other important ports are Patras, Volo, Corfu, Kalamata, and Laurion. The following table shows the total value of special Greek commerce for the given years:—

	1887.	1892.	1897.	1898.
Imports	131,849,325 fr.	119,306,007 fr.	116,363,348 fr.	152,083,634 fr.
Exports	102,652,487 ,,	82,261,464 ,,	81,708,626 ,,	89,488,100 ,,

Variations in the price and quantity of imported cereals and in the sale of currants account mainly for the marked fluctuations in the returns.

The imports and exports for 1897 were distributed as follows:—

	Imports from.	Exports to.
	Fr.	Fr.
Great Britain	29,486,910	26,763,302
Russia	29,256,722	2,434,927
Austria	11,583,956	8,085,969
Turkey	8,744,476	4,868,893
France	11,686,838	7,641,507
Italy	2,778,343	5,233,428
Germany	7,550,463	4,733,690
United States	3,890,662	3,644,286
Belgium	2,951,694	7,616,747
Rumania	568,817	841,716
Egypt	883,575	2,147,478
Holland	761,588	6,459,878
Other countries	6,219,304	1,236,805
	116,363,348	81,708,626

The principal articles of importation were:—

	1896.		1897.	
	Total Value in Francs.	Imports from the United Kingdom.	Total Value in Francs.	Imports from the United Kingdom.
Cereals	31,010,922	None.	33,118,185	None.
Textiles	22,769,703	14,259,858	21,149,714	13,236,880
Minerals, metals (raw)	13,158,009	9,123,887	12,536,251	9,404,953
Fish, caviar, &c.	3,654,307	1,677,436	4,047,410	1,528,554
Raw hides	3,333,108	369,614	3,565,454	250,311
Wood and timber	4,491,951	49,094	3,783,012	38,658
Minerals, metals (worked)	3,643,241	1,140,186	2,901,537	795,645

The chief articles of exportation were:—

	1896.		1897.	
	Total Value in Francs.	Exports to the United Kingdom.	Total Value in Francs.	Exports to the United Kingdom.
Currants	23,139,527	7,681,585	33,300,223	17,280,263
Ores	17,433,940	7,163,705	19,805,835	6,385,538
Wines	5,094.044	578,590	5,592,725	493,308
Cognac	962,157	1,179	1,081,439	43,389
Figs	3,598,068	24,862	2,553,108	16,860
Tobacco	2,582,708	117,733	1,899,407	66,861
Olive oil	3,041,161	13,848	4,645,785	549,715
Olives	1,138,462	42,527	684,374	19,223
Valonia	3,320,636	2,211,682	1,965,920	701,667
Sponges	1,240,400	173,200	1,040,260	84,820

Greece does not yet possess manufacturing industries on any large scale. In 1889 there were 145 establishments, employing steam of 5568 indicated horse-power. In 1892 the total horse-power employed in all factories was calculated to have increased to 10,000. Among the factories are flour mills, cloth and cotton mills, shipbuilding and engineering works, oil presses, tanneries, powder and dynamite mills. About 100 are established in the neighbourhood of Athens and Piræus.

Agriculture.

Greece is essentially an agricultural country; its prosperity depends on its agricultural products, and more than half the population is occupied in the cultivation of the soil. The land in the plains and valleys is exceedingly rich, and, wherever there is a sufficiency of water, produces magnificent crops. The country, especially since the acquisition of the fertile province of Thessaly, might under a well-developed agricultural system provide a food supply for all its inhabitants and an abundant surplus for exportation. Thessaly alone, indeed, could furnish cereals for the whole of Greece. Unfortunately, however, agriculture is still in a primitive state, and the condition of the rural population has received very inadequate attention from successive Governments. As a rule, countries dependent on agriculture are liable to sudden fluctuations in prosperity, but in Greece the diversity of products is so great that a failure in one class of crops is usually compensated by exceptional abundance in another. Among the causes which have hitherto retarded agricultural progress are the ignorance and conservatism of the peasantry, antiquated methods of cultivation, want of capital, absentee proprietorship, sparsity of population, bad roads, the prevalence of usury, the uncertainty of boundaries and the land tax, which, in the absence of a survey, is levied on ploughing oxen; to these may be added the growing distaste for rural life which has accompanied the spread of education. Large estates are managed under the métayer system; the landlords, who prefer to live in the larger towns, see little of their tenants, and rarely interest themselves in their welfare. A great proportion of the best arable land in Thessaly is owned by persons who reside permanently out of the country. In the Peloponnesos peasant proprietorship is almost universal; elsewhere it is gradually supplanting the métayer system; the small properties vary from 2 or 3 to 50 acres. The extensive State lands have been much encroached upon by neighbouring owners; a considerable portion has also been sold to the peasants. The rich plain of Thessaly suffers from alternate droughts and inundations, and from the ravages of field mice; with improved cultivation, drainage, and irrigation it might be rendered enormously productive. Usury is,

perhaps, a greater scourge to the rural population than any visitation of nature; the institution of agricultural banks, lending money at a fair rate of interest on the security of their land, would do much to rescue the peasants from the clutches of local Shylocks. The following table gives the approximate yield and acreage of agricultural products for 1893:—

Crop.	Acres.	Yield.
Cereals	1,111,500	20,250,000 bushels
Olives	432,000	15,000,000 ℔
Vineyards	336,000	66,000,000 gallons
Currants	168,000	350,000,000 ℔
Figs	52,000	60,000,000 ℔
Cotton	14,800	
Tobacco	12,000	16,000,000 ℔
Various	211,400	
Fallow	1,200,000	
Forest	2,025,400	
	Total, 5,563,100	

In addition to the above there are about 5,000,000 acres of pasture and 3,000,000 acres of waste land. The principal cereals are wheat, barley, maize, oats, sesame, and rye. Rice is grown in the marshy plains of Elis, Bœotia, Marathon, and Missolonghi. The cultivation of vegetables is increasing; beans, peas, and lentils are the most common. Of late years market-gardening has been taken up as a new industry in the neighbourhood of Athens. There is a great variety of fruits. Olive plantations are found everywhere; in 1860 they occupied about 90,000 acres, in 1887 433,701 acres. The annual yield of olive oil is estimated at 25,000,000 kilogrammes, and the value of the oil and fruit exported varies from five to ten million francs. Figs are also abundant, especially in Messenia and the Cyclades. Mulberry trees are planted for the purposes of sericulture. Other fruit trees are the orange, citron, lemon, pomegranate, and almond. Peaches, apricots, pears, cherries, &c. abound, but are seldom scientifically cultivated; the fruit is generally gathered while unripe. Cotton in 1887 occupied 14,984 acres, chiefly near Levadeia. Tobacco plantations in 1893 covered 16,320 acres, yielding 2,840,102 okes (1 oke=2¾ ℔); about half of the annual produce is exported, principally to Egypt, Holland, and Turkey. More important are the vineyards, which occupied in 1887 an area of 306,421 acres. The best wine is made at Patras, on the royal estate at Decelea, and on other estates in Attica; a peculiar flavour is imparted to the wine of the country by the addition of resin. The foreign demand for Greek wines is rapidly increasing; 3,770,257 gallons were exported in 1890, 4,974,196 gallons in 1894. There is also a growing demand for Greek cognac.

Currants.

The currant, by far the most important of Greek exports, is cultivated in a limited area extending along the southern shore of the Gulf of Corinth and the seaboard of the Western Peloponnesos, in Zante, Cephalonia, and Leukas, and in certain districts of Akarnania and Ætolia; attempts to cultivate it elsewhere have generally proved unsuccessful. The history of the currant industry has been a record of extraordinary vicissitudes. Prior to 1877 the currant was exported solely for eating purposes, the amounts for the years 1872 to 1877 being 70,766 tons, 71,222 tons, 76,210 tons, 72,916 tons, 86,947 tons, and 82,181 tons respectively. In 1877, however, the French vineyards began to suffer seriously from the phylloxera, and French wine producers were obliged to have recourse to dried currants, which make an excellent wine for blending purposes. The importation of currants into France at once rose from 881 tons in 1877 to 20,999 tons in 1880, and to 70,401 tons in 1889, or about 20,000 tons more than were imported into England in that year. Meanwhile the total amount of currants produced in Greece had nearly doubled in these thirteen years. The country was seized with a mania for currant planting; every other industry was neglected, and olive, orange, and lemon groves were cut down to make room for the more lucrative growth. The currant growers, in order to increase their production as rapidly as possible, had recourse to loans at a high rate of interest, and the great profits which they made were devoted to further planting, while the loans remained unpaid. A crisis followed rapidly. By 1891 the French vineyards had to a great extent recovered from the disease, and wine producers in France began to clamour against the competition of foreign wines and wine-producing raisins and currants. The import duty on these was thereupon raised from 6 francs to 15 francs per 100 kilos, and was further increased in 1894 to 25 francs. The currant trade with France was thus extinguished; of a crop averaging 160,000 tons, only some 110,000 now found a market. Although a fresh opening for exportation was found in Russia, the value of the fruit dropped from £15 to £5 per ton, a price scarcely covering the cost of cultivation. In July 1895 the Government introduced a measure, since known as the Retention (παρακράτησις) Law, by which it was enacted that every shipper should deliver into depots provided by the Government a weight of currants equivalent to 15 per cent. of the amount which he intended to export. A later law has fixed the quantity to be retained by the State at 10 per cent., which may be increased to 20 per cent., should a representative committee, meeting every summer at Athens, so advise the Government. The currants thus taken over by the Government cannot be exported unless they are reduced to pulp, syrup, or otherwise rendered unsuitable for eating purposes; they may be sold locally for wine-making or distilling, due precautions being taken that they are not used in any other way. The price of exported currants is thus maintained at an artificial figure. The Retention Law, which since 1895 has been voted annually, was passed for a period of ten years in 1899. This pernicious measure, which is in defiance of all economic laws, perpetuates a superfluous production, retards the development of other branches of agriculture, and burdens the Government with vast accumulations of an unmarketable commodity. It might excusably be adopted as a temporary expedient to meet a pressing crisis, but as a permanent system it can only prove detrimental to the country and the currant growers themselves. In 1889 an agricultural bank was established at Patras for the purpose of assisting currant growers. The following table gives the annual currant crop from 1877 to 1898, the figures for the last six years, however, being only approximate.

Year.	Total (Tons).	Exported to Great Britain.	Exported to France.	Year.	Total (Tons).	Exported to Great Britain.	Exported to France.
1877	82,181	...	881	1888	152,965	51,856	43,639
1878	100,004	...	9,086	1889	152,256	49,923	70,401
1879	92,311	...	19,087	1890	147,024	56,846	40,018
1880	92,337	...	20,999	1891	153,997	64,050	40,856
1881	121,994	...	30,315	1892	122,583	53,957	20,627
1882	109,403	51,933	26,282	1893	170,000	60,694	3,187
1883	114,980	52,099	24,815	1894	135,500	57,559	15,060
1884	129,268	59,629	39,198	1895	151,500	51,645	19,067
1885	113,287	55,765	37,730	1896	132,000	49,676	2,815
1886	127,570	48,892	45,000	1897	107,000	52,318	526
1887	127,160	55,549	37,438	1898	140,000	58,115	892

The "peronosporos," a species of white blight, first caused considerable damage in the Greek vineyards in 1892, recurring in 1897 and 1900.

Stock farming.

More than half the cultivable area of Greece is devoted to pasturage. Cattle-rearing, as a rule, is a distinct occupation from agricultural farming; the herds are sent to pasture on the mountains in the summer, and return to the plains at the beginning of winter. The larger cattle are comparatively rare, being kept almost exclusively for agricultural labour; the smaller are very abundant. The native breed of oxen is small; buffaloes are seldom seen except in north-western Thessaly; a few camels are used in the neighbourhood of Parnassos. The Thessalian breed of horses, small but sturdy and enduring, can hardly be taken to represent the celebrated chargers of antiquity. The flocks of long-horned sheep and goats add a picturesque feature to Greek rural scenery. The shepherds' dogs rival those of Bulgaria in ferocity. In 1892 the numbers of the various domestic animals were as follows:—sheep, 2,900,000; goats, 2,000,000; large cattle, 360,000; donkeys, 100,000; horses, 100,000; mules, 52,000; pigs, 25,000; and camels, 44.

Forests.

The forest area (about 2,025,400 acres) is for the most part State property. The principal trees are the oak and the various conifers. In Greece, as in other lands formerly subject to Turkish rule, the forests are not only neglected, but often deliberately destroyed; this great source of national wealth is thus continually diminishing. Every year immense forest fires may be seen raging in the mountains, and many of the most picturesque districts in the country are converted into desolate wildernesses. These conflagrations are mainly the work of shepherds eager to provide increased pasturage for their flocks; they are sometimes, however, due to the carelessness of smokers, and occasionally, it is said, to spontaneous ignition in hot weather. Great damage is also done by the goats, which browse on the young saplings; the pine trees are much injured by the practice of scoring their bark for resin. With the disappearance of the trees the soil of the mountain slopes, deprived of its natural protection, is soon washed away by the rain; the rapid descent of the water causes inundations in the plains, while the uplands become sterile and lose their vegetation. The climate has been affected by the change; rain falls less frequently but with greater violence, and the process of denudation is accelerated. The Government has from time to time made efforts for the protection of the forests, but with little success; a society for the re-afforesting of the country has been formed at Athens under royal patronage.

The chief minerals are silver, lead, zinc, copper manganese,

magnesia, iron, sulphur, and coal. Emery, salt, millstone and gypsum, which are found in considerable quantities, are worked by the Government. The important mines at Laurion, reopened in modern times by a Franco-Italian company, were declared to be State property in 1871; they are now worked by a Greek and a French company. The output of marketable ore in 1899 was as follows:—manganese iron ore, 306,625 tons; hæmatite iron ore, 134,381 tons; calamine or zinc ore, 23,710 tons; lead ore and galena, 15,749 tons; blende of zinc and lead ore, 1195 tons; arsenic lead smokes, 3000 tons, and speiss, 2100 tons: total 486,760 tons, besides 289,292 tons of dressed lead ore, producing 18,360 tons of silver pig lead with about 2000 grams of silver per ton of lead. The total value of the exports from the Laurion mines, which in 1875 amounted to only £150,513, had in 1899 increased to £827,209. The revenue accruing to the Government from all mines and quarries, including those worked by the State, was estimated in the budget for 1900 at 1,115,000 drachmæ. The great abundance of marble in Greece has latterly attracted the attention of foreign capitalists. New quarries have been opened by an English company on the north slope of Mount Pentelikon, and are now connected by rail with Athens and Piræus. The marble on this side of the mountain is harder than that on the south, which alone was worked by the ancients. The estimated output in 1900 was 10,800 tons. White marble is also found at Skyros, Tenos, and Naxos; gray at Stoura and Karystos; variegated at Valaxa and Karystos; green on Taygetos; black at Tenos, and red in Maina.

Mines.

The important drainage works at Lake Copais were taken over by an English company in 1890. The lake covered an area of 58,080 acres, the greater part of which is now rendered fit for cultivation. In 1899, 2,400,000 okes of wheat, 900,000 okes of barley, 680,000 okes of hay, and 590,000 okes of maize, besides other produce, were raised off the reclaimed lands. The drainage works consist of a canal 28 kilometres in length, and a tunnel of 600 metres descending through the mountain to a lower lake, which is connected by a second tunnel with the sea. The canal through the isthmus of Corinth was opened to navigation in November 1893. The total cost of the works, which were begun in 1882, was 70,000,000 francs. The narrowness of the canal, which is only 24 metres broad at the surface, and the strength of the current which passes through it, seriously detract from its utility. The high charges imposed on foreign vessels have proved almost prohibitive. There are reduced rates for ships flying the Greek flag. Up to February 1899, 15,272 vessels had passed through the canal. In 1898 the receipts from Greek ships were 241,921 drachmæ, from foreign ships 19,382 francs gold. The widening of the Euripus Channel at Chalcis to the extent of 21·56 metres was accomplished in 1894. The operations involved the destruction of the Venetian tower which guarded the strait.

Public works.

Internal communication by roads is improving, though much remains to be done, especially as regards the quality of the roads. A considerable impetus was given to road-making under the Trikoupis administration. In 1878 there were only 555 miles of roads; in 1898 there were 2398 miles. Railways were open to traffic in 1900 for a length of 598 miles, an increase of 29 miles since 1892; some 62 miles, which will complete the circle of the Morea railways, are in course of construction. A very important undertaking is the completion of a line from Piræus to the frontier, the contract for which was signed in 1900 between the Greek Government and the Eastern Railways Extension Syndicate. A line connecting Piræus with Larissa was begun in 1890, but in 1894 the English company which had undertaken the contract went into liquidation. The line will now be carried as far as Demerli, in the south of Thessaly, a distance of 218 miles; it will subsequently be continued to some point, not yet determined, on the Turkish frontier. There will be branch lines to Lamia and Chalcis. The establishment of a connexion with the continental railway system, by a junction with the line from Belgrade to Salonika, would be of immense advantage to Greece, and Piræus would become an important place of embarkation for Egypt, India, and the Far East. In 1898 the number of post offices was 372, with 550 employés. The receipts amounted to 1,789,236 francs, the expenditure to 1,870.963 francs. During the year there passed through the post 3,104,050 ordinary letters for the interior, 4,984,902 for foreign destinations; 225,180 registered letters; 139,450 post-cards; 75,712 samples; 5,620,730 printed papers for the interior, 2,519,067 for foreign destinations. In the same year there were 221 telegraph offices with 394 instruments and 9 telephones, employing 974 clerks, whose duties, however, were in most cases divided between the postal and telegraph services. Telegraph lines extended over 5235 miles, with 6240 miles of wires. There were despatched during the year 902,872 inland telegrams, 319,048 foreign, and 19,002 service telegrams. Receipts amounted to 1,211,669 francs, expenditure to 779,925 francs.

Communications.

The financial history of Greece has been unsatisfactory from the outset. Excessive military and naval expenditure (mainly due to repeated and hasty mobilizations), a lax and improvident system of administration, the corruption of political parties, and the instability of the Government, which has rendered impossible the continuous application of any scheme of fiscal reform —all alike have contributed to the economic ruin of the country. For a long series of years preceding the declaration of national insolvency in 1893 successive budgets presented a deficit, which in years of political excitement and military activity assumed enormous proportions: the shortcomings of the budget were supplied by the proceeds of foreign loans, or by means of advances obtained in the country at a high rate of interest. The two loans which had been contracted during the war of independence were extinguished by means of a conversion in 1889. Of the existing foreign loans the earliest is that of 60,000,000 frs., guaranteed by the three protecting Powers in 1832: owing to the payment of interest and amortization by the Powers, the capital amounted in 1871 to 100,392,833 fr.; on this Greece pays an annual sum of 900,000 fr., of which 300,000 have been granted by the Powers as a yearly subvention to King George. The only other existing foreign obligation of early date is the debt to the heirs of King Otho (4,500,000 dr.) contracted in 1868. A large amount of internal debt was incurred between 1848 and 1880, but a considerable proportion of this was redeemed with the proceeds of the foreign loans negotiated after this period. At the end of 1880 the entire national debt, external and internal, stood at 252,652,481 dr. In 1881 the era of great foreign loans began. In that year a 5 per cent. loan of 120,000,000 fr. was raised to defray the expenses of the mobilization of 1880. This was followed in 1884 by a 5 per cent. loan of 170,000,000 fr., of which 100,000,000 was actually issued. The service of these loans was guaranteed by various State revenues. A "patriotic loan" of 30,000,000 dr. without interest, issued during the war excitement of 1885, proved a failure, only 2,723,860 dr. being subscribed. In 1888 a 4 per cent. loan of 135,000,000 fr. was contracted, secured on the receipts of the five State monopolies, the management of which was entrusted to a privileged company. In the following year (1889) two 4 per cent. loans of 30,000,000 fr. and 125,000,000 fr. respectively were issued without guarantee or sinking fund: Greek credit had now apparently attained an established position in the foreign money market, but a decline of public confidence soon became evident. In 1890, of a 5 per cent. loan of 80,000,000 fr. effective, authorized for the construction of the Piræus-Larissa Railway, only 40,050,000 fr. was taken up abroad and 12,900,000 fr. at home; large portions of the proceeds were devoted to other purposes. In 1892 the Government was compelled to make large additions to the internal floating debt, and to borrow 16,500,000 fr. from the National Bank on onerous terms. In 1893 an effort to obtain a foreign loan for the reduction of the forced currency proved unsuccessful. (For the events leading up to the declaration of national bankruptcy in that year see below under *Recent History*.) A funding convention was concluded in the summer, under which the creditors accepted scrip instead of cash payments of interest. A few months later this arrangement was reversed by the Chamber, and on the 13th December a law was passed assigning provisionally to all the foreign loans alike 30 per cent. of the stipulated interest: the reduced coupons were made payable in paper instead of gold, the sinking funds were suspended, and the sums encashed by the monopoly company were confiscated. The causes of the financial catastrophe may be briefly summarized as follows:—(1) The military preparations of 1885–86, with the attendant disorganization of the country; the extraordinary expenditure of these years amounted to 130,987,772 dr. (2) Excessive borrowing abroad, involving a charge for the service of foreign loans altogether disproportionate to the revenue. (3) Remissness in the collection of taxation: the total loss through arrears in a period of ten years (1882–91) was 36,549,202 dr., being in the main attributable to non-payment of direct taxes. (4) The adverse balance of trade, largely due to the neglected condition of agriculture; in the five years preceding the crisis (1888–92) the exports were stated to amount to £19,578,973, while the imports reached £24,890,146; foreign live stock and cereals being imported to the amount of £6,193,579. The proximate cause of the crisis was the rise in the exchange owing to the excessive amount of paper money in circulation. Forced currency was first introduced in 1868, when 15,000,000 dr. in paper money was issued; it was abolished in the following year, but reintroduced in 1877 with a paper issue of 44,000,000 dr. It was abolished a second time in 1884, but again put into circulation in 1885, when paper loans to the amount of 45,000,000 dr. were authorized. In 1893 the total authorized forced currency was 146,000,000 dr., of which 88,000,000 (including 14,000,000 dr. in small notes) was on account of the Government. The rate of exchange, as a rule, varies directly with the amount of paper money in circulation, but, owing to speculation, it is liable to violent fluctuations whenever there is an exceptional demand for gold in the market. In 1893 the gold franc stood at the ratio of 1·60 to the paper drachma: the service of the foreign

Finance.

loans required upwards of 31,000,000 dr. in gold, and any attempt to realize this sum in the market would have involved an outlay equivalent to at least half the budget. With the failure of the projected loan for the withdrawal of the forced currency repudiation became inevitable. The law of the 13th December was not recognized by the national creditors: prolonged negotiations followed, but no arrangement was arrived at till 1897, when the intervention of the Powers after the war with Turkey furnished the opportunity for a definite settlement. It was stipulated that Turkey should receive an indemnity of £T4,000,000 contingent on the evacuation of Thessaly; in order to secure the payment of this sum by Greece without prejudice to the interests of her creditors, and to enable the country to recover from the economic consequences of the war, Great Britain, France, and Russia undertook to guarantee a $2\frac{1}{2}$ per cent. loan of 170,000,000 fr., of which 150,000,000 fr. has been issued. By the preliminary treaty of peace (18th September 1897) an International Financial Commission, composed of six representatives of the Powers, was charged with the payment of the indemnity to Turkey (£T4,000,000), and with "absolute control" over the collection and employment of revenues sufficient for the service of the foreign debt. A law defining the powers of the Commission was passed by the Chamber, 26th February 1898 (o.s.). The revenues assigned to its supervision were the five Government monopolies, the tobacco and stamp duties, and the import duties of Piræus (total annual value estimated at 39,600,000 dr.): the collection was entrusted to a Greek society, which is under the absolute control of the Commission. The returns of Piræus customs (estimated at 10,700,000 dr.) are regarded as an extra guarantee, and are handed over to the Greek Government; when the produce of the other revenues exceeds 28,900,000 dr. the "plus value" or surplus is divided in the proportion of 50·8 per cent. to the Greek Government and 49·2 per cent. to the creditors. The plus values amounted to 3,301,481 dr. in 1898, 3,533,755 dr. in 1899, and 3,442,713 dr. in 1900. Simultaneously with the establishment of the control the interest for the Monopoly Loan was fixed at 43 per cent., for the Funding Loan at 40 per cent., and for the other loans at 32 per cent. of the original interest. With the revenues at its disposal the International Commission has already been enabled to make certain augmentations in the service of the foreign debt; since 1900 it has begun to take measures for the reduction of the forced currency, of which 2,000,000 dr. will be annually bought up and destroyed till the amount in circulation is reduced to 40,000,000 dr. On the 1st January 1901 the authorized paper issue was 164,000,000 dr., of which 92,000,000 (including 18,000,000 in fractional currency) was on account of the Government; the amount in actual circulation was 148,619,618 dr. The financial commission retains its powers until the extinction of all the foreign loans contracted since 1881. Though its activity is mainly limited to the administration of the assigned revenues, it has exercised a beneficial influence over the whole domain of Greek finance. No change can be made in its composition or working without the consent of the six Powers, and none of the officials employed in the collection of the revenues subject to its control can be dismissed or transferred without its consent. It thus constitutes an element of stability and order which cannot fail to react on the general administration. It is unable, however, to control the expenditure or to assert any direct influence over the Government, with which the responsibility still rests for an improved system of collection, a more efficient staff of functionaries, and the repression of smuggling. The country has shown a remarkable vitality in recovering from the disasters of 1897, and should it in future obtain a respite from paroxysms of military and political excitement, its financial regeneration will be assured.

The following table gives the actual expenditure and receipts for the period 1889–99 inclusive:—

Year.	Actual Receipts.	Actual Expenditure.	Surplus or Deficit.
	Drachmæ.	Drachmæ.	Drachmæ.
1889	83,731,591	110,772,327	− 27,040,736
1890	79,931,795	125,932,579	− 46,000,784
1891	90,321,872	122,836,385	− 32,514,513
1892	95,465,569	107,283,498	− 11,817,929
1893	96,723,418	92,133,565	+ 4,589,853
1894	102,885,643	85,135,752	+ 17,749,891
1895	94,657,065	91,641,967	+ 3,015,098
1896	96,931,726	90,890,607	+ 6,041,119
1897	92,485,825	137,043,929	− 44,558,104
1898	104,949,718	110,341,431	− 5,391,713
1899	111,318,273	104,586,504	+ 6,731,769

The budget estimates for 1901 were as follows:—Civil list, 1,325,000 dr.; pensions, payment of deputies, &c., 7,433,763 dr.; public debt, 32,344,624 dr.; foreign affairs, 2,846,018 dr.; justice, 6,243,573 dr.; interior, 15,140,566 dr.; religion, 5,392,457 dr.; army, 17,393,014 dr.; navy, 7,123,947 dr.; finance, 7,129,947 dr.; collection of revenue, 9,438,235 dr.; various expenditure, 6,910,628 dr.—total, 118,721,772 dr.

Banking, &c.

The two privileged banks in Greece are the National Bank, founded in 1841; capital, 20,000,000 francs, in 20,000 shares of 1000 francs each, fully paid up; reserve fund, 13,500,000 francs; notes in circulation, 126,900,000 francs; and the Ionian Bank, incorporated in 1839; capital paid up, £315,500, in 12,620 shares of £25 each; notes in circulation, about 13,000,000 francs. The National Bank has its central establishment at Athens, with 33 branches throughout the country. The headquarters of the Ionian Bank are in London; it has 5 branches in Greece. The privileged Epiro-Thessalian Bank ceased to exist from 12th January 1900, when it was amalgamated with the National Bank. There are three other banking companies in Athens, and several private banks. Greece entered the Latin Monetary Union in 1868. The monetary unit is the new drachma, equivalent to the franc, and divided into 100 lepta or centimes. There are nickel coins of 20, 10, and 5 lepta, copper coins of 10 and 5 lepta. Gold and silver coins were minted in Paris between 1868 and 1884, but have since practically disappeared from the country. The paper currency consists of 500-dr., 100-dr., 25-dr., 10-dr., and 5-dr. notes; there are also fractional notes for 2 dr. and 1 dr. The decimal system of weights and measures was adopted in 1876, but some of the old Turkish standards are still in general use.

Ionian Islands.—Since their annexation to Greece in 1864, the history of the "Ionian Islands" (Corfu, Paxos, Cephalonia, Santa Maura, Ithaca, Zante, and Cerigo) has been uneventful. Corfu (Kerkyra) with Paxos; Cephalonia; Santa Maura (Leukas) with Ithaca (Thiaki); and Zante (Zakynthos) each form separate nomarchies or departments, the population of which in 1896 has been given above. Cerigo (Kýthera) now forms part of the nomarchy of Laconia. The beautiful island of *Corfu* has latterly suffered a decline of prosperity. Centralization at Athens has affected some of the local industries and institutions; the university, founded by Lord Guildford, has been abolished; commerce has considerably diminished, partly owing to the fact that the neighbouring coasts of Albania and Epirus now trade directly with Trieste, Fiume, and Marseilles, and the number of winter visitors has decreased owing to the growing popularity of Cairo, Algiers, and other health resorts. In recent years the stagnation of trade has been more marked owing to successive failures in the olive and wine crops, the staple products of the island. The total exports, which in 1895 were valued at £147,200 (£20,579 to the United Kingdom), were estimated in 1898 at only £87,809 (£3754 to the United Kingdom), and in 1899 at £60,815 (£6937 to the United Kingdom). The imports, which in 1896 reached £238,346 (£63,012 from the United Kingdom), were valued in 1898 at £158,426 (£21,326 from the United Kingdom), and in 1899 at £126,471 (£16,833 from the United Kingdom). Corfu and the other Ionian Islands have retained the exemption from direct taxation which they enjoyed under the British protectorate; in lieu of this there is an *ad valorem* tax of $20\frac{1}{2}$ per cent. on exported oil and a tax of 6 per cent. on wine exported to Greek ports; these commodities are further liable to an export duty of $1\frac{1}{2}$ per cent., which is levied on all agricultural produce and articles of local manufacture for the maintenance and construction of roads. The excellent roads, which date from the British administration, are kept in fair repair. Agriculture has made little progress in Corfu; many of the landed proprietors live in the town, and pay little attention to their estates, which are let out to the peasants on the *métayer* system. The unproductiveness of the olive trees in recent years is stated to be largely due to neglect. Among the principal industrial establishments of Corfu are steam oil-presses and flour mills, soap and candle factories, tanneries, and a playing-cards factory. The substantial residence of the British High Commissioners, built in the time of Sir Thomas Maitland, is now a royal palace. In the

neighbourhood of the town is the Villa Monrepos, built by Sir Frederick Adam, and now occasionally occupied by the Greek royal family. The Ionian Academy, founded by Lord Guildford, contains a library and a museum. Near the village of Gastouri is the remarkable Achilleion, once the residence of the Empress Elizabeth of Austria. The house, which is decorated in the Pompeian style, is said to have cost upwards of 5,000,000 francs; it commands a magnificent view, and is surrounded by beautiful gardens. The small rocky island of *Paxos* numbers about 5000 inhabitants. *Cephalonia*, the largest of the Ionian Islands, contains the highest mountain in the group, Mount Ænos or Monte Nero (5300 feet), the slopes of which are still partly covered with beautiful forests of pine (*abies Cephalonica*). Argostoli (population 9172) and Lixouri (population 5414), the principal towns, stand respectively on the east and west shores of the gulf of Livadi, a long inlet on the western side of the island. Currants, which are not grown in Corfu, form one of the principal products of Cephalonia, Santa Maura, and Ithaca. The total exports from these islands in 1898 were estimated at £161,008 (currants £118,958), in 1899 at £135,935 (currants £94,610). The currants are mainly exported to Holland. The total imports in 1898 were £228,705 (£35,450 from the United Kingdom); in 1899, £222,315 (£33,850 from the United Kingdom). The excess of imports over exports is covered by remittances from natives trading abroad. The island of *Ithaca* is inhabited by an industrious agricultural and seafaring population (11,409 in 1896). The ships of the enterprising islanders appear in every port of the Mediterranean, and carry on a busy traffic on the rivers Danube and Pruth. The wine of Ithaca enjoys a high reputation. In latter years the prosperity of the islands has declined, and there has been a considerable emigration to Australia. The remarkable Cyclopean fortress on Mount Ætos, commonly called the Castle of Ulysses, was excavated by Schliemann in 1878. In view of the theory latterly supported by Professor Dörpfeld, that Leukas is the Ithaca of Homer, excavations on the island were carried out by that scholar and Herr Goekup in 1900 and 1901, but without important results. *Leukas*, which owes its name to its white limestone cliffs, was formerly connected with the mainland. The intervening lagoon is shallow, but a passage is being opened which will be navigable to ships of considerable tonnage. The population of Leukas, with that of the small adjacent islands, in 1896 was 31,769. The fertile and beautiful *Zante* has not recovered its prosperity since the earthquakes of 1893, and many of the public and private buildings remain in a dilapidated condition. The island has also suffered severely from the crisis in the currant trade, hitherto its principal source of wealth. *Cerigo*, which has no geographical connexion with the other islands, is rocky, and comparatively unproductive. A large proportion of the male population goes abroad for harvest work during the summer. Quails are captured in great numbers in the spring and autumn, and are exported alive. The population in 1896 was 12,306. The small neighbouring island of *Cerigotto* or Antikýthera has latterly been brought into notice, owing to the remarkable discovery of ancient statues at the bottom of the sea near its coast (January 1901). A signal station was established here during the Cretan insurrection of 1897, by which messages were transmitted from Crete to Athens. The total population of the Ionian Islands was 265,279 in 1896.

Cyclades and Sporades.—The Cyclades, a compact group of islands in the Greek Archipelago, form a cluster around the island of *Syros*, the principal town of which, Syra, officially known as Hermopolis, is the capital of a department. Population, 134,747. The islands, though seldom visited by foreigners, are for the most part highly interesting and picturesque, notwithstanding their somewhat barren appearance when viewed from the sea; many of them bear traces of the feudal rule of Venetian families in the Middle Ages, and their inhabitants in general may be regarded as presenting the best type of the Greek race. To the student of antiquity the most interesting islands of the group are: *Delos* (*q.v.*), one of the greatest centres of ancient religious, political, and commercial life, where an important series of researches has been latterly carried out by French archæologists; *Melos*, where, in addition to various buildings of the Hellenic and Roman periods, the large prehistoric stronghold of Phylakopi has been excavated by members of the British school at Athens; and *Thera* (Santorin), the ancient capital of which has been explored by Baron Hiller von Gaertringen. Thera is also of special interest to geologists owing to its remarkable volcanic phenomena. *Naxos*, the largest and most fertile island of the group, contains the highest mountain in the Cyclades (Zia, 3290 feet); the island annually exports upwards of 2000 tons of emery, a State monopoly, the proceeds of which are now hypothecated to the foreign debt. The oak woods of *Keos* (Zeá) and *Ios* furnish considerable supplies of valonia. *Kimolos*, which is absolutely treeless, produces fuller's-earth. The famous marble quarries of *Paros* have been practically abandoned in modern times; the marble of *Tenos* is now worked by a British syndicate. The mineral wealth of the Cyclades has hitherto been much neglected; iron ore is exported from *Seriphos*, manganese and sulphur from Melos, and volcanic cement (pozzolana) from Santorin. Other articles of export are wine, brandy, hides, and tobacco. *Kythnos*, Melos, and other islands possess hot springs with therapeutic qualities. The prosperity of Syra, formerly an important distributing centre for the whole Levant, has been declining for several years.

Of the Sporades, or "scattered islands," of the Ægean, only the group known as the North Sporades belongs to Greece, Skiathos, Skopelos, and Ikos being included in the department of Magnesia, and Skyros in that of Eubœa. *Skiathos* is a beautifully wooded and picturesque island; the town stands on a declivity surrounding an excellent harbour. The larger island of *Skopelos* is also well wooded. Almost every householder in both these islands is the owner, joint owner, or skipper of a sailing ship. *Skyros* is fertile, and celebrated for its wheat. The population of the Cyclades and Greek Sporades in 1896 was as follows (the population of small adjacent islands is included in some of the figures):—

Cyclades.

Syros	27,774	Santorin	14,472
Mykonos	4,403	Anaphe	643
Zeá	5,019	Amorgos	4,286
Kythnos	4,353	Melos	5,310
Seriphos	3,851	Siphnos	4,060
Andros	18,809	Kimolos	1,655
Tenos	12,300	Pholegandros	1,000
Naxos	15,608	Sikinos	697
Paros	8,336	Ios	2,171

Sporades.

Skopelos	5,295	Skyros	3,512
Ikos	653	Skiathos	2,790

(J. D. B.)

Recent History (1862–1899).

Recent Greek history is little more than a record of successive episodes in the prolonged struggle of the race to attain national unity. The Greeks never acquiesced in the narrow limits assigned to the kingdom in 1832; the exclusion of Crete was regarded as

a special injustice, and Prince Leopold of Saxe-Coburg-Gotha, to whom the throne was then offered, declined to accept it so long as the island was not included in the new realm. At the outbreak of the Russo-Turkish war in 1854, the Greek army was mobilized, and an insurrection was fomented in Epirus, but the occupation of Piræus by French troops put an end to the dream of national aggrandizement. It was not till 1864 that an accession of territory was obtained by the acquisition of the seven Ionian Islands, which since 1815 had formed a separate commonwealth under British protection. In 1862 King Otho, the first sovereign of modern Greece, was deposed by a revolution, and next year Prince William George of Schleswig-Holstein-Sonderburg-Glucksburg, whom Great Britain had designated as a suitable candidate for the vacant throne, was elected by the National Assembly with the title of "George I., King of the Hellenes." On 29th October 1863 the new sovereign arrived in Athens, and in the following June the British authorities handed over the Ionian Islands to a Greek commissioner. King George thus began his reign under the most favourable auspices, the patriotic sentiments of the Greeks being flattered by the acquisition of new territory. He was, however, soon confronted with constitutional difficulties; party spirit ran riot at Athens, the ministries which he appointed proved short-lived, his counsellor Count Sponneck became the object of violent attacks, and at the end of 1864 he was compelled to accept an ultra-democratic constitution, drawn up by the National Assembly. This, the sixth constitution voted since the establishment of the kingdom, is that which is still in force. In the following year Count Sponneck left Greece, and the attention of the nation was concentrated on the affairs of Crete. The revolution which broke out in that island received moral and material support from the Greek Government, with the tacit approval of Russia; military preparations were pressed forward at Athens, and cruisers were purchased, but the king, aware of the inability of Greece to attain her ends by warlike means, discouraged a provocative attitude towards Turkey, and eventually dismissed the bellicose Cabinet of Koumoundouros. The removal of a powerful minister commanding a large parliamentary majority constituted an important precedent in the exercise of the royal prerogative; the king adopted a similar course with regard to Delyannis in 1892 and 1897. The relations with the Porte, however, continued to grow worse, and Hobart Pasha, with a Turkish fleet, made a demonstration off Syra. The Cretan insurrection was finally crushed in the spring of 1869, and a conference of the Powers, which assembled that year at Paris, imposed a settlement of the Turkish dispute on Greece, but took no steps on behalf of the Cretans. In 1870 the murder of several Englishmen by brigands in the neighbourhood of Athens produced an unfavourable impression in Europe; in the following year the confiscation of the Laurion mines, which had been ceded to a Franco-Italian company, provoked energetic action on the part of France and Italy. In 1875, after an acute constitutional crisis, Charilaos Trikoupis, who but ten months previously had been imprisoned for denouncing the Crown in a newspaper article, was summoned to form a Cabinet. This remarkable man, the only great statesman whom modern Greece has produced, exercised an extraordinary influence over his countrymen for the next twenty years; had he been able to maintain himself uninterruptedly in power during that period, Greece might have escaped a long succession of misfortunes. His principal opponent, Theodore Delyannis, succeeded in rallying a strong body of adherents, and political parties, hitherto divided into numerous factions, centred around these two prominent figures.

Accession of George I.

In 1877 the outbreak of the Russo-Turkish war produced a fever of excitement in Greece; it was felt that the quarrels of the party leaders compromised the interests of the country, and the populace of Athens insisted on the formation of a coalition Cabinet. The "great" or "œcumenical" ministry, as it was called, now came into existence under the presidency of the veteran Kanaris; in reality, however, it was controlled by Trikoupis, who, recognizing the unpreparedness of the country, resolved on a pacific policy. The capture of Plevna by the Russians brought about the fall of the "œcumenical" ministry, and Koumoundouros and Delyannis, who succeeded to power, ordered the invasion of Thessaly. Their warlike energies, however, were soon checked by the signing of the San Stefano Treaty, in which the claims of Greece to an extension of frontier were altogether ignored. At the Berlin Congress two Greek delegates obtained a hearing on the proposal of Lord Salisbury. The Congress decided that the rectification of the frontier should be left to Turkey and Greece, the mediation of the Powers being proposed in case of non-agreement; it was suggested, however, that the rectified frontier should extend from the valley of the Peneus on the east to the mouth of the Kalamas, opposite the southern extremity of Corfu, on the west. In 1879 a Greco-Turkish commission for the delimitation met first at Prevesa, and subsequently at Constantinople, but its conferences were without result, the Turkish commissioners declining the boundary suggested at Berlin. Greece then invoked the arbitration of the Powers, and the settlement of the question was undertaken by a conference of ambassadors at Berlin (1880). The line approved by the conference was practically that suggested by the Congress; Turkey, however, refused to accept it, and the Greek army was once more mobilized. It was evident, however, that nothing could be gained by an appeal to arms, the Powers not being prepared to apply coercion to Turkey. By a convention signed at Constantinople in July 1881, the demarcation was entrusted to a commission representing the six Powers and the two interested parties. The line drawn ran westwards from a point between the mouth of the Peneus and Platamona to the summits of Mounts Kritiri and Zygos, thence following the course of the river Arta to its mouth. An area of 13,395 square kilometres, with a population of 300,000 souls, was thus added to the kingdom, while Turkey was left in possession of Iannina, Metzovo, and most of Epirus. The ceded territory was occupied by Greek troops before the close of the year.

New frontier, 1881.

In 1882 Trikoupis came into power at the head of a strong party, over which he exercised an influence and authority hitherto unknown in Greek political life. With the exception of three brief intervals (May 1885 to May 1886, October 1890 to February 1892, and a few months in 1893), he continued in office for the next twelve years. The reforms which he introduced during this period were generally of an unpopular character, and were loudly denounced by his democratic rivals; most of them were cancelled during the intervals when his opponent Delyannis occupied the premiership. The same want of continuity proved fatal to the somewhat ambitious financial programme which he now inaugurated. While pursuing a cautious foreign policy, and keeping in control the rash impetuosity of his fellow-countrymen, he shared to the full the national desire for expansion, but he looked to the development of the material resources of the country as a necessary preliminary to the realization of the dreams of Hellenism.

Trikoupis and Delyannis.

With this view he endeavoured to attract foreign capital to the country, and the confidence which he inspired in financial circles abroad enabled him to contract a number of loans and to better the financial situation by a series of conversions. Under a stable, wise, and economical administration this far-reaching programme might perhaps have been carried out with success, but the vicissitudes of party politics and the periodical outbursts of national sentiment rendered its realization impossible. In April 1885 Trikoupis fell from power, and a few months later the indignation excited in Greece by the revolution of Philippopolis placed Delyannis once more at the head of a warlike movement. The army and fleet were again mobilized with a view to exacting territorial compensation for the aggrandizement of Bulgaria, and several conflicts with the Turkish troops took place on the frontier. The Powers, after repeatedly inviting the Delyannis Cabinet to disarm, established a blockade of Piræus and other Greek ports (8th May 1886), France alone declining to co-operate in this measure. Delyannis resigned (11th May) and Trikoupis, who succeeded to power, issued a decree of disarmament (25th May). Hostilities, however, continued on the frontier, and the blockade was not raised till 7th June. Trikoupis had now to face the serious financial situation brought about by the military activity of his predecessor. He imposed heavy taxation, which the people, for the time at least, bore without murmuring, and he continued to inspire such confidence abroad that Greek securities maintained their price in the foreign market. It was ominous, however, that a loan which he issued in 1890 was only partially covered. Meanwhile the Cretan difficulty had become once more a source of trouble to Greece. In 1889 Trikoupis was grossly deceived by the Turkish Government, which, after inducing him to dissuade the Cretans from opposing the occupation of certain fortified posts, issued a firman annulling many important provisions in the constitution of the island. The indignation in Greece was intense, and popular discontent was increased by the success of the Bulgarians in obtaining the *exequatur* of the Sultan for a number of bishops in Macedonia. In the autumn of 1890 Trikoupis was beaten at the elections, and Delyannis, who had promised the people a radical reform of the taxation, succeeded to power. He proved unequal, however, to cope with the financial difficulty, which now became urgent; and the king, perceiving that a crisis was imminent, dismissed him and recalled Trikoupis. The hope of averting national bankruptcy depended on the possibility of raising a loan by which the rapid depreciation of the paper currency might be arrested, but foreign financiers demanded guarantees which seemed likely to prove hurtful to Greek susceptibilities; an agitation was raised at Athens, and Trikoupis suddenly resigned (May 1893). His conduct at this juncture appears to have been due to some misunderstandings which had arisen between him and the king. The Sotiropoulos-Rhalles ministry which followed effected a temporary settlement with the national creditors, but Trikoupis, returning to power in the autumn, at once annulled the arrangement. He now proceeded to a series of arbitrary measures which provoked the severest criticism throughout Europe and exposed Greece to the determined hostility of Germany. A law was hastily passed which deprived the creditors of 70 per cent. of their interest, and the proceeds of the revenues conceded to the monopoly bondholders were seized (December 1893). Long negotiations followed, resulting in an arrangement which was subsequently reversed by the German bondholders. In January 1895 Trikoupis resigned office, in consequence of a disagreement with the Crown Prince on a question of military discipline. His popularity had vanished, his health was shattered, and he determined to abandon his political career. His death at Cannes (11th April 1896), on the eve of a great national convulsion, deprived Greece of his masterly guidance and sober judgment at a critical moment in her history.

Nationalist agitation, 1896.

His funeral took place at Athens on 23rd April, while the city was still decorated with flags and garlands after the celebration of the Olympic games. The revival of the ancient festival, which drew together multitudes of Greeks from abroad, led to a lively awakening of the national sentiment, hitherto depressed by the economic misfortunes of the kingdom, and a secret patriotic society, known as the *Ethniké Hetæria*, began to develop prodigious activity, enrolling members from every rank of life and establishing branches in all parts of the Hellenic world. The society had been founded in 1894, by a handful of young officers who considered that the military organization of the country was neglected by the Government; its principal aim was the preparation of an insurrectionary movement in Macedonia, which, owing to the activity of the Bulgarians and the reconciliation of Prince Ferdinand with Russia, seemed likely to be withdrawn for ever from the domain of Greek irredentism. The outbreak of another insurrection in Crete supplied the means of creating a diversion for Turkey while the movement in Macedonia was being matured; arms and volunteers were shipped to the island, but the society was as yet unable to force the hand of the Government, and Delyannis, who had succeeded Trikoupis in 1895, loyally aided the Powers in the restoration of order by advising the Cretans to accept the constitution of 1896. The appearance of strong insurgent bands in Macedonia in the summer of that year testified to the activity of the society and provoked the remonstrances of the Powers, while the spread of its propaganda in the army led to the issue of a royal rescript announcing grand military manœuvres, the formation of a standing camp, and the rearmament of the troops with a new weapon (6th December). The objects of the society were effectually furthered by the evident determination of the Porte to evade the application of the stipulated reforms in Crete; the Cretan Christians lost patience, and indignation was widespread in Greece. Emissaries of the society were despatched to the island, and affairs were brought to a climax by an outbreak at Canea on 4th February 1897. The Turkish troops fired on the Christians, thousands of whom took refuge on the warships of the Powers, and a portion of the town was consumed by fire.

Cretan crisis, 1897.

Delyannis now announced that the Government had abandoned the policy of abstention. On the 6th two warships were despatched to Canea, and on the 10th a torpedo flotilla, commanded by Prince George, left Piræus amid tumultuous demonstrations. The ostensible object of these measures was the protection of Greek subjects in Crete, and Delyannis was still anxious to avoid a definite rupture with Turkey, but the Ethniké Hetæria had found means to influence several members of the ministry and to alarm the king. Prince George, who had received orders to prevent the landing of Turkish reinforcements on the island, soon withdrew from Cretan waters owing to the decisive attitude adopted by the commanders of the international squadron. A note was now addressed by the Government to the Powers, declaring that Greece could no longer remain a passive spectator of events in Crete, and on 13th February a force of 1500 men, under Colonel Vassos, embarked at Piræus. On the same day a Greek warship fired on a Turkish steam yacht which was conveying troops from Candia to Sitia. Landing

near Canea on the night of the 14th, Colonel Vassos issued a proclamation announcing the occupation of Crete in the name of King George. He had received orders to expel the Turkish garrisons from the fortresses, but his advance on Canea was arrested by the international occupation of that town, and after a few engagements with the Turkish troops and irregulars he withdrew into the interior of the island. Proposals for the coercion of Greece were now put forward by Germany, but Great Britain declined to take action until an understanding had been arrived at with regard to the future government of Crete. Eventually (2nd March) collective notes were addressed to the Greek and Turkish Governments announcing the decision of the Powers that (1) Crete could in no case in present circumstances be annexed to Greece; (2) in view of the delays caused by Turkey in the application of the reforms, Crete should be endowed with an effective autonomous administration, calculated to ensure it a separate government, under the suzerainty of the Sultan. Greece was at the same time summoned to remove its army and fleet within the space of six days, and Turkey was warned that its troops must for the present be concentrated in the fortified towns and ultimately withdrawn from the island. The action of the Powers produced the utmost exasperation at Athens; the populace demanded war with Turkey and the annexation of Crete, and the Government drew up a reply to the Powers in which, while expressing the conviction that autonomy would prove a failure, it indicated its readiness to withdraw some of the ships, but declined to recall the army. A suggestion that the troops might receive a European mandate for the preservation of order in the island proved unacceptable to the Powers, owing to the aggressive action of Colonel Vassos after his arrival. Meanwhile troops, volunteers, and munitions of war were hurriedly despatched to the Turkish frontier in anticipation of an international blockade of the Greek ports, but the Powers contented themselves with a pacific blockade of Crete, and military preparations went on unimpeded.

War with Turkey.

While the Powers dallied, the danger of war increased; on 29th March the Crown Prince assumed command of the Greek troops in Thessaly, and a few days later hostilities were precipitated by the irregular forces of the Ethniké Hetæria, which attacked several Turkish outposts near Grevena. According to a report of its proceedings, subsequently published by the society, this invasion received the previous sanction of the prime minister. On 17th April Turkey declared war. The disastrous campaign which followed was of short duration, and it was evident from the outset that the Greeks had greatly underrated the military strength of their opponents (see below, *Greco-Turkish War*). Delyannis was invited by the king to resign, but refusing to do so was dismissed (29th April). His successor, Rhalles, after recalling the army from Crete (9th May) invoked the mediation of the Powers, and an armistice was concluded on the 19th of that month. Thus ended an unfortunate enterprise, which was undertaken in the hope that discord among the Powers would lead to a European war and the dismemberment of Turkey. Greek interference in Crete had at least the result of compelling Europe to withdraw the island for ever from Turkish rule. The conditions of peace put forward by Turkey included a war indemnity of £10,000,000 and the retention of Thessaly; the latter demand, however, was resolutely opposed by Great Britain, and the indemnity was subsequently reduced to £4,000,000. The definitive treaty of peace, which was signed at Constantinople on 6th December, contained a provision for a slight modification of the frontier, designed to afford Turkey certain strategical advantages; the delimitation was carried out by a commission composed of military delegates of the Powers and representatives of the interested parties. The evacuation of Thessaly by the Turkish troops was completed in June 1898. An immediate result of the war was the institution of an international financial commission at Athens, charged with the control of certain revenues assigned to the service of the national debt. The state of the country after the conclusion of hostilities was deplorable; the towns of Northern Greece and the islands were crowded with destitute refugees from Thessaly; violent recriminations prevailed at Athens, and the position of the dynasty seemed endangered. A reaction, however, set in, in consequence of an attempt to assassinate King George (28th February 1898), whose great services to the nation in obtaining favourable terms from the Powers began to receive general recognition. In the following summer the king made a tour through the country, and was everywhere received with enthusiasm. In the autumn the Powers, on the initiative of Russia, decided to entrust Prince George of Greece with the government of Crete; on 26th November an intimation that the prince had been appointed High Commissioner in the island was formally conveyed to the court of Athens, and on 21st December he landed in Crete amid enthusiastic demonstrations (see CRETE).

(J. D. B.)

GRECO-TURKISH WAR, 1897.

This war involved two practically distinct campaigns, in Thessaly and in Epirus. Upon the Thessalian frontier the

Turks, early in March, had concentrated six divisions (about 58,000 men), 1500 sabres, and 156 guns, under Edhem Pasha. A seventh division was rendered available a little later. The Greeks numbered about 45,000 infantry, 800 cavalry, and 96 guns, under the Crown Prince. On both sides there was a considerable dispersion of forces along the frontier. The Turkish navy, an important factor in the war of 1877–78, had become paralytic ten years later, and the Greek squadron held complete command of the sea. Expeditionary forces directed against the Turkish line of communications might have influenced the course of the campaign; but for such work the Greeks were quite unprepared, and beyond bombarding one or two insignificant ports on the coast-line, and aiding the transport of troops from Athens to Volo, the navy practically accomplished nothing. On the 9th and 10th April Greek irregulars crossed the frontier, either with a view to provoke hostilities or in the hope of fomenting a rising in Macedonia. On the 16th and 17th some fighting occurred, in which Greek regulars took part; and on the 18th Edhem Pasha, whose headquarters had for some time been established at Elassona, ordered a general advance. The Turkish plan was to turn the Greek left and to bring on a decisive action, but this was not carried out. In the centre the Turks occupied the Meluna Pass on the 19th, and the way was practically open to Larissa. The Turkish right wing, however, moving on Damani and the Reveni Pass, encountered resistance, and the left wing was temporarily checked by the Greeks among the mountains near Nezeros. At Mati, covering the road to Tyrnavo, the Greeks entrenched themselves. Here sharp fighting occurred on the 21st and 22nd, during which the Greeks sought to turn the right flank of the superior Turkish central column. On the 23rd fighting was renewed, and the advance guard of the Turkish left column, which had been reinforced, and had pressed back the Greeks, reached Deliler. The Turkish forces had now drawn together, and the Greeks were threatened on both flanks. In the evening a general retreat was ordered, and the loose discipline of the Greek army was at once manifested. Rumours of disaster spread among the ranks, and wild panic supervened. There was nothing to prevent an orderly retirement upon Larissa, which had been fortified and provisioned, and which offered a good defensive position. The general *débâcle* could not, however, be arrested, and in great disorder the mass of the Greek army fled southwards to Pharsala. There was no pursuit, and the Turkish commander-in-chief did not reach Larissa till the 27th. Thus ended the first phase of the war, in which the Greeks showed tenacity in defence, which proved fruitless by reason of initially bad strategic dispositions entailing far too great dispersion, and also because there was no plan of action beyond a general desire to avoid risking a defeat which might prevent the expected risings in Macedonia and elsewhere. The handling of the Turkish army showed little skill or enterprise; but on both sides political considerations tended to prevent the application of sound military principles.

Larissa being abandoned by the Greeks, Velestino, the junction of the Thessalian railways, where there was a strong position covering Volo, seemed to be the natural rallying point for the Greek army. Here the support of the fleet would have been secured, and a Turkish advance across the Othrys range upon Athens could not have taken place until the flanking position had been captured. Whether by direction or by natural impulse, however, the mass of the Greek troops made for Pharsala, where some order was re-established, and preparations were made to resist attack. The importance of Velestino was recognized by sending a brigade thither by railway from Pharsala, and the inferior Greek army was thus split into two portions, separated by nearly 40 miles. On 27th April a Turkish reconnaissance on Velestino was repulsed, and further fighting occurred on the 29th and 30th, in which the Greeks under Colonel Smolenski held their own. Meanwhile the Turks made preparations to attack Pharsala, and on 5th May the Greeks were driven from their positions in front of the town by three divisions. Further fighting followed on the 6th, and in the evening the Greek army retired in fair order upon Domokos. It was intended to turn the Greek left with the first division under Hairi Pasha, but the flanking force did not arrive in time to bring about a decisive result. The abandonment of Pharsala involved that of Velestino, where the Turks had obtained no advantage, and on the evening of the 5th Colonel Smolenski began a retirement upon Halmyros. Again delaying, Edhem Pasha did not attack Domokos till the 17th, giving the Greeks time to entrench their positions. The attack was delivered in three columns, of which the right was checked and the centre failed to take the Greek trenches and suffered much loss. The left column, however, menaced the line of retreat, and the Greek army abandoned the whole position during the night. No effective stand was made at the Furka Pass, which was evacuated on the following night. Colonel Smolenski, who arrived on the 18th from Halmyros, was directed to hold the pass of Thermopylæ. The Greek forces being much demoralized, the intervention of the Tsar was invoked by telegraph; and the latter sent a personal appeal to the Sultan, who directed a suspension of hostilities. On the 20th an armistice was arranged.

In Epirus at the outbreak of war about 15,000 Greeks, including a cavalry regiment and five batteries, the whole under Colonel Manos, occupied a line of defence from Arta to Peta. The Turks, about 28,000 strong, with forty-eight guns, under Achmet Hifsi Pasha, were distributed mainly at Iannina, Pentepagadia, and in front of Arta. On 18th April the Turks commenced a three days' bombardment of Arta; but successive attempts to take the bridge were repulsed, and during the night of the 21st they retired on Philippiada, 26 miles distant, which was attacked and occupied by Colonel Manos on the 23rd. The Greeks then advanced to Pentepagadia, meeting with little resistance. Their difficulties now began. After some skirmishing on the 27th, the position held by their advanced force near Homopulos was attacked on the 28th. The attack was renewed on the 29th, and no Greek reinforcements were forthcoming when needed. The Euzones made a good defence, but were driven back by superior force, and a retreat was ordered, which quickly degenerated into panic-stricken flight to and across the Arta. Reinforcements, including 2500 Epirote volunteers, were sent to Arta from Athens, and on 12th May another incursion into Turkish territory began, the apparent object being to occupy a portion of the country in view of the breakdown in Thessaly and the probability that hostilities would shortly end. The advance was made in three columns, while the Epirote volunteers were landed near the mouth of the Luro river with the idea of cutting off the Turkish garrison of Prevesa. The centre column, consisting of a brigade, three squadrons, and two batteries, which were intended to take up and hold a defensive position, attacked the Turks near Strevina on the 13th. The Greeks fought well, and being reinforced by a battalion from the left column, resumed the offensive on the following day, and fairly held their own. On the night of the 15th a retreat was ordered and well carried out. The volunteers landed at the mouth of the Luro were attacked and routed with heavy loss.

The campaign in Epirus thus failed as completely as that in Thessaly. Under the terms of the treaty of peace, signed on 20th September, and arranged by the European Powers, Turkey obtained an indemnity of £T4,000,000, and a rectification of the Thessalian frontier, carrying with it some strategic advantage. History records few more unjustifiable wars than that which Greece gratuitously provoked. The Greek troops on several occasions showed tenacity and endurance, but discipline and cohesion were manifestly wanting. Many of the officers were incapable; the campaign was gravely mismanaged; and politics, which led to the war, impeded its operations. On the other hand, the fruits of the German tuition, which began in 1880, and received a powerful stimulus by the appointment of General von der Goltz in 1883, were shown in the Turkish army. The mobilization was on the whole smoothly carried out, and the newly completed railways greatly facilitated the concentration on the frontier. The young school of officers trained by General von der Goltz displayed ability, and the artillery at Pharsala and Domokos was well handled. The superior leading was, however, not conspicuously successful; and while the rank and file again showed excellent military qualities, political conditions and the Oriental predilection for half-measures and for denying full responsibility and full powers to commanders in the field enfeebled the conduct of the campaign. On account of the total want of careful and systematic peace training on both sides, a war which presented several interesting strategic problems provided warnings in place of military lessons. (G. S. C.)

Modern Greek Literature.

The works of modern Greek poets and prose writers are usually classified according to the form of the language in which they are written. In contemporary literature two distinct forms of the modern language present themselves—the vernacular (ἡ καθομιλουμένη) and the purified (ἡ καθαρεύουσα). The former is the oral language, spoken by the whole Greek world, with local dialectic variations; the latter is based on the Greek of the Hellenistic writers, modified, but not essentially altered, in successive ages by the popular speech. At the time of the War of Independence the enthusiasm of the Greeks and the Philhellenes was fired by the memory of an illustrious past, and at its close a classical reaction followed: the ancient nomenclature was introduced in every department of the new state, towns and districts received their former names, and children were christened after Greek heroes and philosophers instead of the Christian saints. In the literary revival which attended the national movement, two schools of writers made their appearance—the purists, who, rejecting the spoken idiom as degenerate and corrupt, aimed at the restoration of the classical language, and the vulgarists, who regarded the vernacular or "Romaic" as the genuine and legitimate representative of the ancient tongue. A controversy which had existed in former times was thus revived, with the result that a state of confusion still prevails in the national literature. The classical scholar who is as yet unacquainted with modern Greek will find in the pages of an ordinary periodical or newspaper specimens of the conventional literary language which he can read with ease side by side with poems or even prose in the vernacular which he will be altogether unable to interpret.

The vernacular or oral language is never taught, but is universally spoken. It has been evolved from the ancient language by a natural and regular process, similar to that which has produced the Romance languages from the Latin, or the Russian, Bulgarian, and Servian from the old Slavonic. In the case of Greek the process has been less complete; the speech of illiterate peasants in Epirus and Asia Minor approximates more nearly to the classical tongue than Italian to Latin. If we except certain peculiar dialects, such as the Tzakonian in the south-eastern Morea, the differences of idiom prevailing among the members of a widely scattered race are surprisingly slight. This comparative uniformity may be attributed to the maritime character of the Greeks, to the intercourse between the great centres of population, such as Constantinople, Smyrna, Salonika, and Alexandria, to the influence of the Church, and still more to that of the schools, which even in the darkest period of the national history were maintained throughout the Greek world. The phonetic modifications which occur in the different dialects are also relatively insignificant. A comparative study of these can hardly fail to suggest the conclusion that the ancient pronunciation is to a large extent represented by the modern. There are, apparently, some important deviations, *e.g.*, the prevailing itacism, or use of the "i" sound for η, υ, ει, οι, υι, the converse use of the "u" sound for "i," and the pronunciation of the diphthongs αυ and ευ as "af" and "ef," are undoubted corruptions; but in these and other instances the original pronunciation has been retained in various dialects. The arbitrary systems of pronunciation adopted in England, France, and Germany differ from each other in essential particulars. Notwithstanding certain variations in the dialects, the general uniformity in the use of the accents, which rarely deviates from that denoted by the Alexandrine grammarians, shows the system of accentuation according to metrical quantity to be erroneous. The spoken Greek, like the other languages of modern Europe, has received an analytic development. The case endings show a tendency to disappear or to assimilate; the dative is totally lost, the genitive is often replaced by a preposition with the accusative. In the conjugations the perfect and future tenses are formed by the auxiliaries ἔχω and θέλω; the infinitive has ceased to exist except in a shortened form with the auxiliary. As in the Romance languages, a new nominative is often formed from the accusative: thus ὁ ἀνήρ, ἡ γυνή, ἡ νύξ become ὁ ἄνδρας, ἡ γυναῖκα, ἡ νύχτα; the nominative plural of all feminine nouns ends in -ς; the final nasal in noun and verb forms usually disappears; the final syllable, as well as the first syllable, is sometimes lost, as in φεῖδι, ξεῖδι, λᾶδι, for ὀφείδιον, ὀξείδιον, ἐλαΐδιον. The retention of the passive, which has disappeared in most languages of the Indo-European family, is a peculiar feature. The spoken language contains a large number of foreign words.

The Greek vernacular has developed on parallel lines with the modern European languages, and in obedience to the same laws; like them, it might have grown into a literary language had any great writers arisen in the Middle Ages to do for it what Dante and his successors of the *trecento* did for Italian. But the effort to adapt it to the requirements of modern literature will hardly prove successful. In the first place, the national sentiment of the Greeks will always prompt them to imitate the classical writers, and so far as possible to appropriate their diction. The beauty and dignity of the ancient tongue will always possess such an attraction for cultivated writers that they will be led insensibly to adopt its forms and borrow from its wealth of phrase and idiom. In the next place, a certain literary tradition and usage has already been formed which cannot easily be broken down. For more than half a century the generally accepted written language, half modern half ancient, has been in use in the schools, the university, the parliament, the state departments, and the pulpit, and its influence upon the speech of the more educated classes is already noticeable. It largely

owes its present form—though a fixed standard is still lacking—to the influence and teaching of Koraës (1748–1833), whose literary activity was contemporary with the national renascence. As in the time of the decadence a κοινὴ διάλεκτος stood midway between the classical language and the popular speech, so at the beginning of the 19th century there existed a common literary dialect, largely influenced by the vernacular, but retaining the characteristics of the old Hellenistic, from which it was derived by an unbroken literary tradition. This written language Koraës took as the basis of his reforms, purging it of foreign elements, preserving its classical remnants and enlarging its vocabulary with words borrowed from the ancient lexicon or, in case of need, invented in accordance with a fixed principle. He thus adopted a middle course, discountenancing alike the pedantry of the purists and the over-confident optimism of the vulgarists, who found in the uncouth popular speech all the material for a *langue savante*. The language which he thus endeavoured to shape and reconstruct is, of course, conventional and artificial. In course of time it will probably tend to approach the vernacular, while the latter will gradually be modified by the spread of education. The spoken and written languages, however, will always be separated by a wide interval.

Many of the best poets of modern Greece have written in the vernacular, which is best adapted for the natural and spontaneous expression of the feelings. Dionysios Solomos (1798–1857), the greatest of them all, employed the dialect of the Ionian Islands. Of his lyrics, which are full of poetic fire and inspiration, the most celebrated is his "Ode to Liberty." Other poets, of what may be described as the Ionic school, such as Andreas Kalvos (1796–1869), Julius Typaldos (1814–83), John Zampelios (1787–1856), and Gerasimos Markoras (born 1826), followed his example in using the Heptanesian dialect. On the other hand, Georgios Terzetes (1806–74), Aristotle Valaorites (1824–79) and Gerasimos Mavrogiannes, though natives of the Ionian Islands, adopted in their lyrics the language of the Klephtic ballads—in other words, the vernacular of the Pindus range and the mountainous district of Epirus. This dialect had at least the advantage of being generally current throughout the mainland, while it derived distinction from the heroic exploits of the champions of Greek liberty. The poems of Valaorites, which are characterized by vivid imagination and grace of style, have made a deep impression on the nation. Other poets who largely employed the Epirotic dialect and drew their inspiration from the Klephtic songs were John Vilaras (1771–1823), George Zalokostas (1805–1857) in his lyric pieces, and Theodore Aphentoules, a Cretan (died 1893). With the poems of this group may be classed those of Demetrius Bikelas (born 1835). The popular language has been generally adopted by the younger generation of poets, among whom may be mentioned Aristomenes Probelegios (born 1850), George Bizyenos (1853–96), George Drosines, Kostes Palamas (born 1859), John Polémes, Argyres Ephthaliotes, and Jacob Polylas (died 1896).

Contemporary with the first-mentioned or Ionic group, there existed at Constantinople a school of poets who wrote in the accepted literary language, and whose writings served as models for the later group which gathered at Athens after the emancipation of Greece. The literary traditions founded by Alexander Rizos Rhangabés (1810–1892) and the brothers Alexander and Panagiotis Soutzos (1803–63 and 1800–68), who belonged to Phanariot families, were maintained in Athens by Spiridion Basiliades (1843–74), Angelos Vlachos (born 1838), John Karasoutzas (1824–73), Demetrios Paparrhegopoulos (1843–1873), and Achilles Paraschos (born 1838). The last, a poet of fine feeling, has also employed the popular language. In general the practice of versification in the literary language has declined, though sedulously encouraged by the university of Athens, and fostered by annual poetic competitions with prizes provided by patriotic citizens. Greek lyric poetry during the first half of the century was mainly inspired by the patriotic sentiment aroused by the struggle for independence, but in the present generation it often shows a tendency towards the philosophic and contemplative mood under the influence of Western models. Among recent satirists, George Soures (born 1853) occupies a unique position. He reviews social and political events in the Ῥωμῃός, a witty little newspaper written entirely in verse, which is read with delight by all classes of the population.

There has been an abundant production of dramatic literature in recent years. In addition to Alexander Rhangabés, John Zampelios, and the two Soutzos, who belong to the past generation, Kleon Rhangabes, Angelos Vlachos, Demetrios Koromelas, Basiliades and Bernadakes are the most prominent among modern dramatic writers. Numerous translations of foreign masterpieces have appeared, among which the metrical versions of *Romeo and Juliet*, *Othello*, *King Lear*, *Hamlet*, *Macbeth*, and *The Merchant of Venice*, by Demetrios Bikelas, deserve mention as examples of artistic excellence. Goethe's *Faust* has been rendered into verse by Probelegios, and *Hamlet*, *Antony and Cleopatra*, *Coriolanus* and *Julius Cæsar*, into prose by Damiralis.

Almost all the prose writers have employed the literary language. In historical research the Greeks continue to display much activity and erudition, but no great work comparable to Spiridion Trikoupis's *History of the Revolution* has appeared in the present generation. A history of the Greek nation from the earliest times to the present day, by Spiridion Lampros, and a general history of the 19th century by Karolides, have recently been published. The valuable Μνημεῖα of Sathas, the μελέται Βυζαντινῆς ἱστορίας of Spiridion Zampelios, and Mavrogiannes's *History of the Ionian Islands* deserve special mention, as well as the essays of Bikelas, which treat of the Byzantine and modern epochs of Greek history. Some of the last-named were translated into English by the late marquis of Bute. Among the writers on jurisprudence are Peter Paparrhegopoulos, Kalligas, Basileios Œkonomedes, and Nikolaos Saripolos. Brailas-Armenes and John Skaltzounes, the latter an opponent of Darwin, have written philosophical works. The *Ecclesiastical History* of Diomedes Kyriakos and the *Theological Treatises* of Archbishop Latas should be noted. The best-known writers of philological works are Constantine Kontos, a strong advocate of literary purism, George Hatzidakes, Theodore Papademetrakopoulos, and John Psichari; in archæology, Stephen Koumanoudes, Panagiotes Kavvadias, and Christos Tsountas have won a recognized position among scholars. John Svoronos is a high authority on numismatics. The works of John Hatzidakis on mathematics, Anast. Christomanos on chemistry, and Demetrios Aeginetes on astronomy are well known.

The earlier works of fiction, written in the period succeeding the emancipation of Greece, were much affected by foreign influence. Modern Greece has not produced any great novelist. The Κρητικοὶ γάμοι of Spiridion Zampelios, the scene of which is laid in Crete, and the *Thanos Blechas* of Kalligas are interesting, the former for accuracy of historical detail, the latter as a picture of peasant life in the mountains of Greece. Original novel writing has not been much cultivated, but translations of foreign romances abound. In later times the short story

has come into vogue through the example of D. Bikelas, whose tales have acquired great popularity; one of them, *Loukis Laras*, has been translated into many languages. The example of Bikelas has been followed by Drosinis Karkavitzas, Ephthaliotis, Xenopoulos, and many others. The most distinguished of the writers who adhere to the vernacular in prose is John Psichari, professor of the École des Hautes Études in Paris. He is the recognized leader of the vulgarists. Among the best-known of his works are Τὸ *ταξεῖδί μου*, a narrative of a journey in Greek lands, Τὄνειρο *τοῦ Γιαννίρη*, Ἡ *Ζούλεα*, and ὁ Μάγος. The tales of Karkavitzas and Ephthaliotis are also in the vernacular. Among the younger of M. Psichari's followers is M. Pallis, who has recently published a translation of the *Iliad*. Owing to the limited resources of the popular language, the writers of this school are sometimes compelled to employ strange and little-known words borrowed from the various dialects. The vernacular has never been adopted by writers on scientific subjects, owing to its inherent unsuitability and the incongruity arising from the introduction of technical terms derived from the ancient language. Notwithstanding the zeal of its adherents, it seems unlikely to maintain its place in literature outside the domain of poetry; nor can any other result be expected, unless its advocates succeed in reforming the system of public instruction in Greece.

Many periodicals are published at Athens, among which may be mentioned the *Athena*, edited by Constantine Kontos, the *Ethniké Agogí*, a continuation of the old *Hestia*, the *Harmonia*, and the *Διάπλασις τῶν παίδων*, an educational review. The Parnassos, the Archæological Society, and other learned bodies issue annual or quarterly reports. The Greek journals are both numerous and widely read. They contain much clever writing, which is often marred by inaccuracy and a deficient sense of responsibility. For many years the *Nea Heméra* of Trieste exerted a considerable influence over the Greek world, owing to the able political reviews of its editor, Anastasios Byzantios (died 1898), a publicist of remarkable insight and judgment.

Greek Church. See ORTHODOX EASTERN CHURCH.

Green, John Richard (1837–1883), English historian, was born at Oxford on 12th December 1837, and educated at Magdalen College School and at Jesus College, where he obtained an open scholarship. On leaving Oxford he took orders and became the incumbent of St Philip's, Stepney. His preaching was eloquent and able; he worked diligently among his poor parishioners, and won their affection by his ready sympathy. Meanwhile he studied history in a scholarly fashion, and wrote much for the *Saturday Review*. Partly because his health was weak and partly because he ceased to agree with the teaching of the Church of England, he abandoned clerical life and devoted himself to history; in 1868 he took the post of librarian at Lambeth, but his health was already breaking down, and he was attacked by consumption. His *Short History of the English People* (1874) at once attained extraordinary popularity, and was afterwards expanded in a work of four volumes (1877–80). Green is pre-eminently a picturesque historian; he had a vivid imagination and a keen eye for colour. His chief aim was to depict the progressive life of the English people rather than to write a political history of the English state. In accomplishing this aim he worked up the results of wide reading into a series of brilliant pictures. While generally accurate in his statement of facts, and showing a firm grasp of the main tendency of a period, he often builds more on his authorities than is warranted by their words, and is apt to overlook points which would have forced him to modify his representations and lower the tone of his colours. From his animated pages thousands have learnt to take pleasure in the history of their own people, but could scarcely learn to appreciate the complexity inherent in all historical movement. His style is extremely bright, but it lacks sobriety and presents some affectations. His later histories, *The Making of England* (1882) and *The Conquest of England* (1883), are more soberly written than his earlier books, and are valuable contributions to historical knowledge. Green died at Mentone on 7th March 1883. He was a singularly attractive man, of wide intellectual sympathies and an enthusiastic temperament; his good-humour was unfailing and he was a brilliant talker; and his work was done with admirable courage in spite of ill-health. It is an open secret that Mrs Humphry Ward's *Robert Elsmere* was largely a portrait of him. In 1877 J. R. Green married Miss Alice Stopford; and Mrs Green, besides writing a memoir of her husband, prefixed to the 1888 edition of his *Short History*, has herself done valuable work as a historian, particularly in her *Henry II.* in the "English Statesmen" series (1888) and her *Town Life in the 15th Century* (1894). (W. HU.)

See also the *Letters of J. R. Green* (1901), edited by Leslie Stephen.

Green, Thomas Hill (1836–1882), English philosopher, the most typical English representative of the school of thought called *Neo-Kantian*, or *Neo-Hegelian*, was born on 7th April 1836 at Birkin, a village in the West Riding of Yorkshire, of which his father was rector. On the paternal side he was descended from Oliver Cromwell, whose honest, sturdy independence of character he seemed to have inherited. His education was conducted entirely at home until, at the age of four-

teen, he entered Rugby, where he remained five years. In 1855 he became an undergraduate member of Balliol College, Oxford, of which society he was, in 1860, elected Fellow. His life, henceforth, was devoted to teaching (mainly philosophical) in the university—first as college tutor, afterwards, from 1878 until his death (at Oxford on the 26th of March 1882), as Whyte's Professor of Moral Philosophy. The lectures he delivered as professor form the substance of his two most important works, viz., the *Prolegomena to Ethics*, and the *Lectures on the Principles of Political Obligation*, which contain the whole of his positive constructive teaching. These works were not published until after his death, but Green's views were previously known to the outside world indirectly through the *Introduction* to the standard edition of Hume's works (by Green and Grose), in which the doctrine of the "English" or "Empirical" Philosophy was exhaustively examined.

Hume's Empiricism, combined with a belief in biological evolution (derived from Herbert Spencer), was the chief feature in English thought during the third quarter of the 19th century. Green represents primarily the reaction against doctrines which, when carried out to their logical conclusion, not only "rendered all philosophy futile," but were fatal to practical life. By reducing the human mind to a series of unrelated atomic sensations, this teaching destroyed the possibility of knowledge, and, further, by representing man as a "being who is simply the result of natural forces," it made conduct, or any theory of conduct, unmeaning; for life in any human, intelligible sense implies a personal self which (1) *knows* what to do, (2) has *power* to do it. Green was thus driven, not theoretically, but as a practical necessity, to raise again the whole question of Man in relation to Nature. When (he held) we have discovered what Man in himself is, and what his relation to his environment, we shall then know his function—what he is fitted to do. In the light of this knowledge we shall be able to formulate the Moral Code, which, in turn, will serve as a criterion of actual civic and social institutions. These form, naturally and necessarily, the objective expression of moral ideas, and it is in some civic or social whole that the Moral Ideal must finally take concrete shape.

To ask "What is Man?" is to ask "What is Experience?" for Experience means that of which I am conscious. The facts of consciousness are the only facts which, to begin with, we are justified in asserting to exist. On the other hand, they are valid evidence for whatever is necessary to their own explanation, *i.e.*, for whatever is logically involved in them. Now the most striking characteristic of man, that in fact which marks him specially, as contrasted with other animals, is *self*-consciousness. The simplest mental act into which we can analyse the operations of the human mind—the act of sense-perception—is never merely a *change*, physical or psychical, but is the *consciousness* of a change. Human experience consists, not of processes in an animal organism, but of these processes recognized as such. That which we perceive is from the outset an apprehended fact—that is to say, it cannot be analysed into isolated elements (so-called sensations) which, as such, are not constituents of consciousness at all, but exists from the first as a synthesis of relations in a consciousness which keeps distinct the "self" and the various elements of the "object," though holding all together in the unity of the act of perception. In other words, the whole mental structure we call knowledge consists, in its simplest equally with its most complex constituents, of the "work of the mind." Locke and Hume held that the work of the mind was *eo ipso* unreal because it was "made by" man and not "given to" man. It thus represented a subjective creation, not an objective fact. But this consequence follows only upon the assumption that the work of the mind is arbitrary, an assumption shown to be unjustified by the results of exact science, with the distinction, universally recognized, which such science draws between truth and falsehood, between the real and "mere ideas." This (obviously valid) distinction logically involves the consequence that the object, or content, of knowledge, viz., reality, is an intelligible ideal reality, a system of thought relations, a spiritual cosmos. How is the existence of this ideal whole to be accounted for? Only by the existence of some "principle which renders all relations possible and is itself determined by none of them"; an eternal self-consciousness which knows in whole what we know in part. To God the world *is*, to man the world *becomes*. Human experience is God gradually made manifest.

Carrying on the same analytical method into the special department of Moral Philosophy, Green held that Ethics applies to the peculiar conditions of Social life that investigation into man's nature which Metaphysics began. The Faculty employed in this further investigation is no "separate moral Faculty," but that same Reason which is the source of all our knowledge—Ethical and other. Self-reflexion gradually reveals to us human capacity, human function, with, consequently, human responsibility. It brings out into clear consciousness certain potentialities in the realization of which man's true good must consist. As the result of this analysis, combined with an investigation into the surroundings man lives in, a "content"—a Moral Code—becomes gradually evolved. Personal good is perceived to be realizable only by making actual the conceptions thus arrived at. So long as these remain potential, or ideal, they form the motive of action; motive consisting always in the idea of some "end" or "good" which man presents to himself as an end in the attainment of which he would be satisfied, that is, in the realization of which he would find his true self. The determination to realize the self in some definite way constitutes an "act of Will," which, as thus constituted, is neither arbitrary nor externally determined. For the motive which may be said to be its cause lies *in* the man himself, and the identification of the Self with such a motive is a *Self*-determination, which is at once both rational and free. The "Freedom of Man" is constituted, not by a supposed ability to do anything he may choose, but in the power to identify himself with that true good which reason reveals to him as *his* true good. This good consists in the realization of personal character; hence the final good, *i.e.*, the Moral Ideal, as a whole, can be realized only in some Society of persons who, while remaining ends to themselves in the sense that their individuality is not lost but rendered more perfect, find this perfection attainable only when the separate individualities are integrated as parts of a social whole. Society is as necessary to form persons as persons are to constitute Society. Social union is the indispensable condition of the development of the special capacities of the individual members. Human self-perfection cannot be gained in isolation; it is attainable only in interrelation with fellow-citizens in the Social Community.

The law of our being, so revealed, involves in its turn civic or political duties. Moral goodness cannot be limited to, still less constituted by, the cultivation of self-regarding virtues, but consists in the attempt to realize in practice that moral ideal which self-analysis has revealed to us as *our* ideal. From this fact arises the ground of political obligation, for the institutions of political or civic life are the concrete embodiment of moral ideas in terms of our day and generation. But, as Society exists only for the proper development of persons, we have a criterion by which to test these institutions, viz., do they, or do they not, contribute to the development of moral character in the individual citizens? It is obvious that the final Moral

Ideal is not realized in any body of civic institutions actually existing, but the same analysis which demonstrates this deficiency points out the direction which a true development will take. Hence arises the conception of rights and duties which *should be* maintained by Law, as opposed to those actually maintained; with the further consequence that it may become occasionally a moral duty to rebel against the State in the interest of the State itself, that is, in order better to subserve that end or function which constitutes the *raison d'être* of the State. The State does not consist in any definite concrete organization formed once for all. It represents a "general will" which is a desire for a common good. Its basis is not a coercive authority imposed upon the citizens from without, but consists in the spiritual recognition, on the part of the citizens, of that which constitutes their true nature. "Will, not force, is the basis of the State."

Green's teaching was, directly and indirectly, the most potent philosophical influence in England during the last quarter of the 19th century, while his enthusiasm for a common citizenship, and his personal example in practical municipal life, inspired much of the effort made, in the years succeeding his death, to bring the universities more into touch with the people and to break down the rigour of class distinctions.

Of his philosophical doctrine proper, the most striking characteristic is Integration, as opposed to Disintegration, both in Thought and in Reality. "That which is" is a *whole*, not an *aggregate*; an organic complex of parts, not a mechanical mass; a "whole" too not material but spiritual, a "world of Thought-relations." On the critical side this teaching is now admittedly valid against the older Empiricism, and the cogency of the reasoning by which his constructive theory is supported is generally recognized. Nevertheless, Green's statement of his conclusions presents important difficulties. Even apart from the impossibility of conceiving a whole of relations which are relations and nothing else (this objection is perhaps largely verbal), no explanation is given of the fact (obvious in experience) that the spiritual entities of which the Universe is composed *appear* material. Certain elements present themselves in Feeling which seem stubbornly to resist any attempt to explain them in terms of Thought. While, again, legitimately insisting upon Personality as a fundamental constituent in any true theory of Reality, the relation between human individualities and the divine Person is left vague and obscure; nor is it easy to see how the existence of several individualities—human or divine—in *one* cosmos is theoretically possible. It is at the solution of these two questions that Philosophy in the immediate future may be expected to work.

Green's most important treatise—the *Prolegomena to Ethics*—practically complete in manuscript at his death—was published in the year following. Shortly afterwards Nettleship's standard edition of his *Works* (exclusive of the *Prolegomena*) appeared in three volumes: vol. i. containing reprints of Green's criticism of Hume, Spencer, Lewes; vol. ii. Lectures on Kant, on Logic, on the Principles of Political Obligation; vol. iii. Miscellanies, preceded by a full *Memoir* by the Editor. The *Principles of Political Obligation* was afterwards published in separate form. A criticism of *Neo-Hegelianism* will be found in Professor Seth's *Hegelianism and Personality*, to which may be added articles in *Mind* (January and April 1884) by Mr A. J. Balfour and Professor Henry Sidgwick. (W. H. F*.)

Greenaway, Kate (1846–1901), English artist and book illustrator, was the daughter of John Greenaway, a well-known draughtsman and engraver on wood, and was born in London on the 17th of March 1846. After a course of study at South Kensington, at "Heatherley's" life classes, and at the Slade School, Kate Greenaway began, in 1868, to exhibit water-colour drawings at the Dudley Gallery, London. Her more remarkable early work, however, consisted of Christmas cards, which, by reason of their quaint beauty of design and charm of draughtsmanship, enjoyed an extraordinary vogue. Her subjects were, in the main, young girls, children, flowers, and landscape; and the air of artless simplicity, freshness, humour, and purity of these little works so appealed to public and artists alike, that the enthusiastic welcome habitually accorded to them is to be attributed to something more than love of novelty. In the line she had struck out Kate Greenaway was encouraged by H. Stacy Marks, R.A., and she refused to listen to those friends who urged her to return to a more conventional manner. Thenceforward her illustrations for children (such as for *Little Folks*, 1873, *et seq.*) attracted much attention. In 1877 her drawings at the Dudley Gallery were sold for £54, and her Royal Academy picture for eighteen guineas; and in the same year she began to draw for the *Illustrated London News*. In the year 1879 she produced *Under the Window*, of which 150,000 copies are said to have been sold, and of which French and German editions were also issued. Then followed *The Birthday Book*, *Mother Goose*, *Little Ann*, and other books for children, which were appreciated not less by adults, and were to be found on sale in the bookshops of every capital in Europe and in the cities of America. The extraordinary success achieved by the young girl may be estimated by the amounts paid to her as her share of the profits: for *Under the Window* she received £1130; for *The Birthday Book*, £1250; for *Mother Goose*, £905; and for *Little Ann*, £567. These four books alone produced a clear return of £8000. "Toy-books" though they were, these little works created a revolution in illustration, and so were of real importance; they were loudly applauded by John Ruskin (*Art of England* and *Fors Clavigera*), by Ernest Chesneau and Arsène Alexandre in France, by Dr Muther in Germany, and by leading art-critics throughout the world. In 1890 Kate Greenaway was elected a member of the Royal Institute of Painters in Water Colours, and in 1891, 1894, and 1898 she exhibited water-colour drawings (including illustrations for her books) at the gallery of the Fine Art Society (by which a representative selection was exhibited in 1902), where they surprised the world by the infinite delicacy, tenderness, and grace which they displayed. A leading feature in Miss Greenaway's work was her revival of the delightfully quaint costume of the beginning of the 19th century; this lent humour to her fancy, and so captivated the public taste that it has been said, with poetic exaggeration, that "Kate Greenaway dressed the children of two continents." Her drawings of children have been compared with Stothard's for grace and with Reynolds's for naturalness, and those of flowers with the work of even Van Huysum and Botticelli. From 1883 to 1897, with a break only in 1896, she issued a series of *Kate Greenaway's Almanacs*. Although she illustrated *The Pied Piper of Hamelin* and other works, the artist preferred to provide her own text; the numerous verses which were found among her papers after her death prove that she might have added to her reputation with her pen. She was possessed of great charm of character. Extremely shy of public notice, she was not less modest in private life; her friendships, though few, were very cordial. She died at Hampstead on 6th November 1901. (M. H. S.)

Greenbacks, a form of paper currency in the United States, so named from the green colour used on the backs of the notes. They are Treasury notes, and were first issued by the Government in 1862, "as a question of hard necessity," to provide for the expenses of the Civil War. The Government, following the example of the banks, had suspended specie payment. The new notes were therefore for the time being an inconvertible paper currency, and, since they were made legal tender, were really a form of fiat money. The first Act, providing for the issue of notes to the amount of $150,000,000, was passed on the 25th February 1862; the Acts of 11th July 1862 and 3rd March 1863 each authorized further issues of $150,000,000. The notes soon depreciated in value, and at the lowest were worth only 35 cents on the dollar. The Act of 12th April 1866 authorized the retirement of $4,000,000 of notes per month, but was repealed two years later. On 1st

January 1879 specie payment was resumed, and the amount of notes then nominally remaining ($346,681,016) was still outstanding on 1st January 1902.

The so-called *Greenback party*, which first came into definite political existence in 1874, was in favour of further increasing the volume of greenbacks. Their candidate for the presidency in 1876 was Peter Cooper, who received 81,740 votes. In 1880 the party, enlarged by fusion with labour reformers, nominated James B. Weaver, and not only polled 307,306 votes, but elected eight representatives to Congress. In 1884 their candidate was General Benjamin F. Butler (also the candidate of the Anti-Monopoly party), who received 133,825 votes. Since then the party has been merged in the Populists.

Green Bay, capital town of Brown county, Wisconsin, U.S.A., in 44° 31′ N. and 88° 00′ W., at the head of Green Bay, at an altitude of 591 feet. It has four railways, the Chicago and North-Western, the Chicago, Milwaukee, and St Paul, the Green Bay and Western, and the Kewaunee, Green Bay, and Western. Its excellent harbour and ample railway facilities give it a large commerce. Its manufactures are chiefly of lumber; the city contains many saw and shingle mills. Population (1880), 7464; (1890), 9069; (1900), 18,684.

Greenbush. See RENSSELAER, N.Y.

Greencastle, capital of Putnam county, Indiana, U.S.A., at an altitude of 762 feet. It is on the Vandalia, the Chicago, Indianapolis, and Louisville, and the Cleveland, Cincinnati, Chicago, and St Louis railways. It is the seat of De Pauw University, a co-educational Methodist-Episcopal institution, founded in 1832. In 1899 this had 22 professors and instructors and 475 students, about one-third of whom were women. Its property exceeded $500,000, and its income for the year was $31,848. Population (1880), 3644; (1890), 4390 (1900), 3661, of whom 143 were foreign-born and 155 negroes.

Greenfield, capital of Franklin county, Massachusetts, U.S.A., including an area of 20 square miles of hill country. The principal village, of the same name as the town, is situated on the northern bank of the Deerfield river, and on the Fitchburg and the Boston and Maine railways, at an altitude of 200 feet. Population of the town (1880), 3903; (1890), 5252; (1900), 7927, of whom 1431 were foreign-born.

GREENLAND.

SINCE 1880 the unknown parts of the coasts of Greenland have been explored by several expeditions. In 1882 Lieutenant Lockwood and Sergeant (afterwards Captain) Brainard, of the United States expedition to Lady Franklin Bay,[1] explored the north-west coast beyond Cape Britannia to a promontory in 83° 24′ N. lat. and 40° 46′ E. long., and they saw to the north-east Cape Washington, in about 83° 38′ N. lat. and 39° 30′ E. long., the most northerly point of land hitherto observed. In July 1892 Lieutenant R. E. Peary and E. Astrup discovered Independence Bay, on the north-east coast, in 81° 37′ N. lat. and 34° 5′ W. long.[2] In May 1895 it was revisited by Peary, who supposed this bay to be a sound communicating with Victoria Inlet on the north-west coast. To the north Heilprin Land and Melville Land were seen stretching northwards, but the probability seemed to be that the coast soon trended north-west. In 1901 Lieutenant Peary rounded the north point, and penetrated as far north as 83° 50′ N. The previously little-known east coast has to a great extent been well explored since 1880. The Danes G. Holm and V. Garde have carefully explored and mapped the coast from Cape Farewell to Angmagssalik, in 66° N. lat.[3] Nansen and his companions also travelled along a part of this coast in 1888.[4] Nordenskiöld visited in the *Sophia* Angmagssalik, in 65° 36′ N. lat., in 1883.[5] Captain C. Ryder, in 1891–92, explored and mapped the large Scoresby Sound, or, more correctly, Scoresby Fjord.[6] Lieutenant G. Amdrup, in 1899, explored the coast from Angmagssalik north to 67° 22′ N. lat.[7] A part of this coast, about 67° N. lat., had also been seen by Nansen in 1882.[8] In 1899 Professor Nathorst explored the land between Franz Josef Fjord and Scoresby Fjord, where the large King Oscar Fjord, connecting Davy's Sound with Franz Joseph Fjord, was discovered.[9] In 1900 Lieutenant Amdrup explored the still unknown east coast from 69° 10′ N. south to 67° N. Only the following portions of the coasts of Greenland still remain unexplored: the east coast between Cape Bismarck in 77° N. lat. and Independence Bay, and the north-east and north coast between this and Cape Washington.

Character of the East Coast.—Our ideas of the east coast of Greenland have been somewhat changed by recent explorations. It is an unusually glaciated coast, evidently owing to the north polar current carrying the ice masses from the north polar basin south-westwards along the land, and giving it an entirely Arctic climate down to Cape Farewell. In some parts the interior ice-covering extends down to the outer coast, while in other parts its margin is situated more inland, and the ice-bare coast-land is deeply intersected by fjords extending far into the interior, where they are blocked by enormous glaciers or "ice-currents" from the interior ice-covering, which discharge masses of icebergs into them. The east coast of Greenland is in this respect highly interesting. All coasts in the world which are much intersected by deep fjords have with very few exceptions a western exposure, *e.g.*, Norway, Scotland, British Columbia and Alaska, Patagonia and Chile, and even Spitsbergen and Novaya Zemlya, whose west coasts are far more intersected than their east ones. Greenland forms the most prominent exception, its eastern coast being quite as much intersected as its western. The reason is to be found in its geographical position, a cold ice-covered polar current running south along the land, while not far outside there is an open warmer sea, a circumstance which, while producing a cold climate, must also give rise to much precipitation, the land being thus exposed to the alternate erosion of a rough atmosphere and large glaciers. On the east coast of Baffin Land and Labrador there are similar conditions. The fact is, that

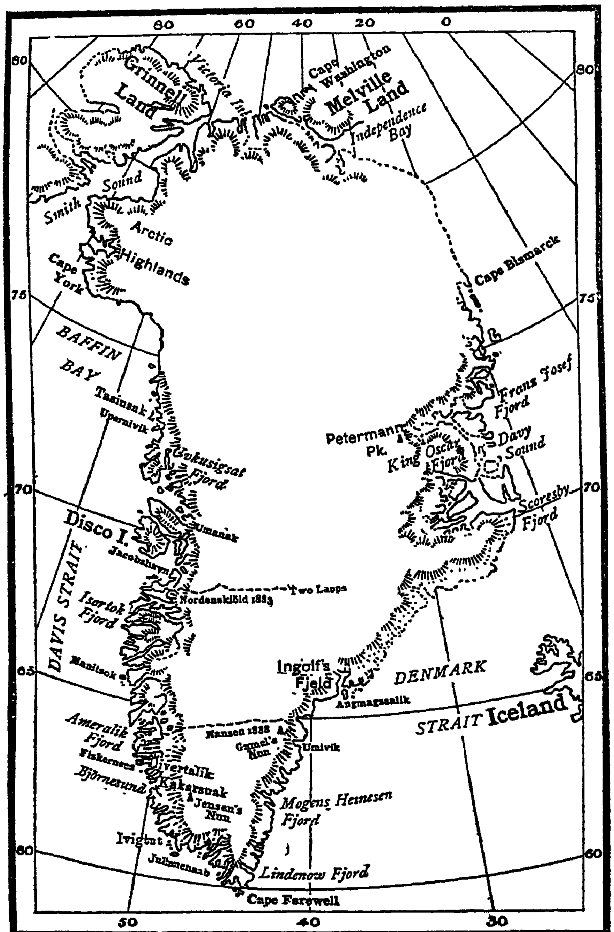
the east coast of Greenland has the largest system of fjords known on the Earth's surface. The Scoresby Fjord has a length of about 180 miles from the outer coast to the point where it is blocked by the glaciers, and with its numerous branches covers an enormous area. Franz Josef Fjord, with its branch King Oscar Fjord, communicating with Davy Sound, seems to form a system of fjords on a similar scale. These fjords are very deep; the greatest depth found by Ryder in Scoresby Sound was 300 fathoms, but there are certainly still greater depths. Assuming that the fjords are submerged or drowned valleys, which is most likely, this indicates that the land was once at



B. V. Darbishire & O. J. R. Howarth, Engl Miles 100 50 0 100 200 300 Oxford, 1901.

SKETCH MAP OF GREENLAND.

least 2000 feet higher, or the sea-level was 2000 feet lower, and probably more. A few soundings made outside this coast seem to indicate that the fjords continue as deep submarine valleys far out into the sea. Along the east coast there are also many high mountains, exceeding 6000 and 7000 feet in height. One of the highest peaks hitherto measured is at Tiningnertok, on the Lindenow Fjord, in 60° 35′ N. lat., which is 7340 feet high. At the bottom of Mogens Heinesen Fjord, 62° 30′ N. lat., the peaks are 6300 feet, and in the region of Umanak, 63° N. lat., they even exceed 6600 feet. At Umivik, where Nansen began his journey across the "inland ice," the highest peak projecting through the ice-covering was Gamél's Nunatak, 6440 feet, in 64° 34′ N. lat. In the region of Angmagssalik, which is very mountainous, the mountains rise to 6500 feet, the most prominent peak being Ingolf's Fjeld, in 66° 20′ N. lat., about 6000 feet, which is seen far off in the sea, and forms an excellent landmark. This is evidently the Blaaserk (*i.e.*, Blue Sark or blue coat) of the old Norsemen, their first landmark on their way from Iceland to the Öster Bygel, the present Julianehaab district, on the south-west coast of Greenland.[1] A little farther north the coast is much lower, rising only to heights of 2000 feet, and just north of 67° 10′ N. lat. only to 500 feet or less.[2] The highest mountains near the inner branches of Scoresby Fjord are about 7000 feet. The Petermann Spitze, near the shore of Franz Josef Fjord, measured by Payer and found to be 11,000 feet, has hitherto been considered to be the highest mountain in Greenland, but according to Nathorst it "is probably only two-thirds as high as Payer supposed," perhaps between 8000 or 9000 feet.

Along the west coast of Greenland the mountains are generally not quite so high, but even there peaks of 5000 and 6000 feet are not uncommon. As a whole the coasts are unusually mountainous, and Greenland forms in this respect an interesting exception, as there is no other known land of such a size so filled along its coasts on all sides with high mountains and deep fjords and valleys.

The "Inland Ice."—The whole interior of Greenland is completely covered by the so-called "inland ice," an enormous glacier forming a regular shield-shaped expanse of snow and glacier ice, and burying all valleys and mountains far below its surface. It rises in the interior to a level of 9000 feet, and in places perhaps 10,000 feet or more, and descends gradually by extremely gentle slopes towards the coasts or the bottom of the fjords on all sides, discharging a great part of its yearly drainage or surplus of precipitation in the form of icebergs in the fjords, the so-called ice-fjords, which are numerous both on the west and the east coast. These icebergs float away, and are gradually melted in the sea, the temperature of which is thus lowered by cold stored up in the interior of Greenland. The last remains of these icebergs are met with in the Atlantic south of Newfoundland. The interior of the inland ice has been explored by several expeditions since 1875. Captain J. A. D. Jensen reached, in 1878, the Jensen Nunataks (5400 feet above the sea), about 45 miles from the western margin, in 62° 50′ N. lat.[3] Nordenskiöld penetrated, in 1883, about 70 miles inland from its western margin in 68° 20′ N. lat., and two Lapps of his expedition went still farther on skis. Peary and Maigaard reached, in 1886, about 100 miles inland from the western margin a height of 7500 feet, in 69° 30′ N. lat. Nansen with five companions crossed, in 1888, the inland ice from the east coast to the west, in about 64° 25′ N. lat., and reached a height of 8922 feet. Peary and Astrup crossed, in 1892, the northern part of the inland ice between 78° and 82° N. lat., reaching a height of about 8000 feet, and determined the northern termination of the ice-covering. Peary made very nearly the same journey again in 1895. Captain V. Garde explored, in 1893, the interior of the inland ice between 61° and 62° N. lat., near its southern termination, and he reached a height of 7080 feet about 60 miles from the margin.[4]

The surface of the inland ice forms in a transverse section from the west to the east coast an extremely

[1] Their second or third landmark was Hvidserk (*i.e.*, white sark or coat), near Hvarf, in the region of Cape Farewell. Hvidserk is one of the most prominent snow-covered mountains on the east or south coast near Cape Farewell. It is difficult, however, for one who has not seen this part of the coast to decide which mountain it may be.

regular curve, almost approaching an arc of a wide circle, which along Nansen's route has its highest ridge somewhat nearer the east than the west coast. The same also seems to be the case farther south. The curve shows, however, slight irregularities in the shape of undulations. The angle of the slope decreases gradually from the margin of the inland ice, where it may be 1° or more, towards the interior, where it is 0°. In the interior the surface of the inland ice is composed of dry snow which never melts, and which is constantly packed and worked smooth by the winds. It extends as a completely even plain of snow, with long, almost imperceptible, undulations or waves, at a height of 8000 to 10,000 feet, obliterating the features of the underlying land, the mountains and valleys of which are completely interred. Over the deepest valleys of the land in the interior this ice-cap must be at least 6000 or 7000 feet thick or more. Approaching the coasts from the interior, the snow of the surface gradually changes its structure. At first it becomes more coarse-grained, like the *Firn Schnee* of the Alps, and is moist by melting during the summer. Nearer the coast, where the melting on the surface is more considerable, the wet snow freezes hard during the winter and is more or less transformed into ice, on the surface of which rivers and lakes are formed, the water of which, however, soon finds its way through crevasses and holes in the ice down to its under surface, and reaches the sea as a sub-glacial river. Near its margin the surface of the inland ice is broken up by numerous large crevasses, formed by the outward motion of the glacier covering the underlying land. The steep ice-walls at the margin of the inland ice show, especially where the motion of the ice is slow, a distinct striation, which indicates the strata of annual precipitation with the intervening thin seams of dust (Nordenskiöld's kryokonite). This is partly dust blown on to the surface of the ice from the ice-bare coast-land and partly the dust of the atmosphere brought down by the falling snow and accumulated on the surface of the glacier's covering by the melting during the summer. In the rapidly moving glaciers of the ice-fjords this striation is not distinctly visible, being evidently obliterated by the strong motion of the ice masses.

The ice-cap of Greenland must to some extent be considered as a viscous mass, which, by the vertical pressure in its interior, is pressed outwards and slowly flows towards the coasts, just as a mass of pitch placed on a table and left to itself will in the course of time flow outwards towards all sides. The motion of the outwards-creeping inland ice will naturally be more independent of the configurations of the underlying land in the interior, where its thickness is so enormous, than near the margin where it is thinner. Here the ice converges into the valleys and moves with increasing velocity in the form of glaciers into the fjords, where they break off as icebergs. The drainage of the interior of Greenland is thus partly given off in the solid form of icebergs, partly by the melting of the snow and ice on the surface of the ice-cap, especially near its western margin, and to some slight extent also by the melting produced on its under side by the interior heat of the Earth.

Glaciers.—After Professor Amund Helland had, in July 1875, discovered the amazingly great velocity, up to 64¾ feet (19·77 m.) in twenty-four hours, with which the glaciers of Greenland move into the sea, the margin of the inland ice and its glaciers was studied by several expeditions. K. J. V. Steenstrup during several years, Captain Hammer in 1879–80, Captain Ryder in 1886–87, Dr Drygalski in 1891–93,[1] and several American expeditions in later years, all examined the question closely. The highest known velocities of glaciers was measured by Ryder in the Upernivik glacier (in 73° N. lat.), where, between the 13th and 14th August of 1886, he found a velocity of 121 feet in twenty-four hours, and an average velocity during several days of 99 feet (Danish).[2] It was, however, ascertained that there is a great difference between the velocities of the glaciers in winter and in summer. For instance, Ryder found that the Upernivik glacier had an average velocity of only 33 feet in April 1887. There seem to be periodical oscillations in the extension of the glaciers and the inland ice similar to those that have been observed on the glaciers of the Alps and elsewhere. But these interesting phenomena have not hitherto been subject to systematic observation, and our knowledge of them is therefore uncertain. Numerous glacial marks, however, such as polished striated rocks, moraines, erratic blocks, &c., prove that the whole of Greenland, even the small islands and skerries outside the coast, has once been covered by the inland ice.

Geology.—It is unnecessary to discuss in detail all the researches into the geology of Greenland during the last quarter of the 19th century: the reader is referred to the excellent series of publications, *Meddelelser om Grönland*, published in Copenhagen, where much valuable information in this respect may be found. The highly interesting Cretaceous and Tertiary strata with plant fossils at Atanikerdluk and other places on the west coast between 69° 25′ and 72° N. lat. have been carefully investigated by K. J. V. Steenstrup, Nordenskiold, and Nathorst, and valuable memoirs on them have been published by Oswald Heer, Nathorst, and Steenstrup. In the southern part of the explored east coast, south of Angmagssalik, no sedimentary rocks with fossils have been found; they are all crystalline schists. In Scoresby Fjord the Ryder expedition found Jurassic deposits, besides basalts and crystalline schists. In the Franz Josef Fjord region Nathorst discovered also deposits of the Silurian and Devonian systems. Numerous raised beaches and terraces, containing shells of marine Mollusca, &c., occur along the whole coast of Greenland, and indicate that the whole of this large island has been raised, or the sea has sunk, in post-Tertiary times, after the inland ice covered its now ice-bare outskirts. In the north along the shores of Smith Sound these traces of the gradual upheaval of the land, or sinking of the sea, are very marked; but they are also very distinct in the south, although not found so high above sea-level, which seems to show that the upheaval has been greater in the north. In Uvkusigsat Fjord (72° 20′ N. lat.) the highest terrace is 480 feet (150 m.) above the sea.[3] On Manitsok (67° 50′ N. lat.) the highest raised beach was 360 feet (108 m.) above the sea.[4] In the Isortok Fjord (67° 11′ N. lat.) the highest raised beach is 380 feet (119·2 m.) above sea-level.[5] In the Ameralik Fjord (64° 14′ N. lat.) the highest marine terrace is about 340 feet (106 m.) above sea-level, and at Ilivertalik (63° 14′ N. lat.), north of Fiskernees, the highest terrace is about 325 feet (101 m.) above the sea. At Kakarsuak, near the Björnesund (62° 50′ N. lat.), a terrace is found at 615 feet (192 m.) above the sea, but it is doubtful whether this is of marine origin.[6] In the Julianehaab district, between 60° and 61° N. lat., the highest marine terraces are found at about 160 feet (50 m.) above the sea.[7] The highest marine terrace

observed in Scoresby Fjord, on the east coast, was 240 feet above sea-level.[1] There is a common belief that during quite recent time the west and south-west coast, within the Danish possessions, has been sinking. Although there are many indications which may make this probable, none of them can be said to be quite decisive.[2]

Native iron has been found by K. J. V. Steenstrup in several places on the west coast enclosed as smaller or larger nodules in the basalt. This iron has very often beautiful Widmannstätten figures like those of iron meteorites.[3] In 1895 Peary found native iron at Cape York; since John Ross's voyage in 1818 it had been known to exist there, and from it the Eskimo got iron for their weapons. In 1897 Peary brought the largest nodule to New York; it was estimated to weigh nearly 100 tons. This iron is considered by several of the first authorities on the subject to be of meteoric origin,[4] but no evidence hitherto given seems to prove decisively that it cannot be telluric. That the nodules found were lying on gneissic rock, with no basaltic rocks in the neighbourhood, does not prove that the iron may not originate from basalt, for the nodules may have been transported by the glaciers, like other erratic blocks, and will stand erosion much longer than the basalt, which may long ago have disappeared. This iron seems, however, in several respects to be unlike the celebrated large nodules of iron found by Nordenskiöld at Uifak on Disco Island, but appears to resemble much more closely the softer kind of iron nodules found by Steenstrup in the basalt;[5] it stands exposure to the air equally well, and has similar Widmannstätten figures very sharp, as is to be expected in such a large mass. It contains, however, more nickel and also phosphorus.

Climate.—The climate of the interior has been found to be of a continental character, with large ranges of temperature, and with an almost permanent anti-cyclonic region over the interior of the inland ice, from which the prevailing winds radiate towards the coasts. On the 64th parallel the mean annual temperature at an elevation of 6560 feet is supposed to be −13° F., or reduced to sea-level 5° F. The mean annual temperature in the interior farther north is supposed to be −10° F. reduced to sea-level. The mean temperature of the warmest month, July, in the interior should be, reduced to sea-level, on the 64th parallel 32° F., and that of the coldest month, January, about −22° F., while in North Greenland it is probably −40° reduced to sea-level. Here we may probably find the lowest temperatures of the northern hemisphere. The interior of Greenland contains both summer and winter a pole of cold, situated in the opposite longitude to that of Siberia, with which it is well able to compete in extreme severity. On Nansen's expedition temperatures of about −49° F. were experienced during the nights in the beginning of September, and the minimum during the winter may probably sink to −90° F. in the interior of the inland ice. These low temperatures are evidently caused by the radiation of heat from the snow-surface in the rarefied air in the interior. The daily range of temperature is therefore very considerable, sometimes amounting to 40°. Such a range is elsewhere found only in deserts, but the surface of the inland ice may be considered to be an elevated desert of snow.[6] The climate of the east coast is on the whole considerably more Arctic than that of the west coast on corresponding latitudes; the land is much more snow-covered, and the snow-line goes considerably lower. The probability also is that there is more precipitation, and that the mean temperatures are lower.[7] The well-known strangely warm and dry *föhn*-winds of Greenland occur both on the west and the east coast; they are more local phenomena than was previously believed, and are formed by cyclonic winds passing over local mountains or also passing down the outer slope of the inland ice.[8]

Fauna and Flora.—It has been a common belief that the fauna and flora of Greenland are essentially European, a circumstance which would make it probable that Greenland has been separated by sea from America during a longer period of time than from Europe. The correctness of this hypothesis may, however, be doubted. The land mammals of Greenland are decidedly more American than European: the musk-ox, the banded lemming (*Cuniculus torquatus*), the white polar wolf, of which there seems to have been an invasion recently round the northern part of the country to the east coast, the Eskimo and the dog,—probably also the reindeer,—have all of them come from America, while the other land mammals, the polar bear, the polar fox, the Arctic hare, the stoat (*Mustela erminea*), are perfectly circumpolar forms. The species of seals and whales are, if anything, more American than European, and so to some extent are the fishes. The bladder-nose seal (*Cystophora cristata*), for instance, may be said to be a Greenland-American species, while a Scandinavian species, such as the grey seal (*Halichœrus grypus*), appears to be very rare both in Greenland and America. Of the sixty-one species of birds breeding in Greenland, eight are European-Asiatic, four are American, and the rest circumpolar or North Atlantic and North Pacific in their distribution.[9] About 310 species of vascular plants are found, of which about forty species are American, forty-four European-Asiatic, fifteen endemic, and the rest common both to America and Europe or Asia. We thus see that the American and the European-Asiatic elements of the flora are nearly equivalent; and if the flora of Arctic North America were better known, the number of plants common to America might be still more enlarged.[10]

At Tasiusak (73° 22′ N. lat.), the most northern civilized settlement in the world, gardening has been attempted without success, but several plants do well in forcing frames. At Umanak (70° 40′ N. lat.) is the most northern garden in the world. Broccoli and radishes grow well, turnips (but not every year), lettuce, and chervil succeed sometimes, but parsley cannot be reared. At Jacobshavn (69° 12′ N. lat.), only some 15 miles from the inland ice, gardening succeeds very well; broccoli and lettuce grow willingly; the spinach produces large leaves; chervil, pepper-grass, leeks, parsley, and turnips grow very well; the radishes are sown and gathered twice during

the summer (June to August). In the south, in the Julianehaab district, even flowering plants, such as aster, nemophilia, and mignonette, are cultivated, and broccoli, spinach, sorrel, chervil, parsley, rhubarb, turnips, lettuce, radishes grow very well. Potatoes give fair results when they are taken good care of, carrots grow to a thickness of one inch and a half, while cabbage does poorly. Strawberries and cucumbers have been ripened in a forcing frame. In the "Kongespeil" (King's mirror) from the 13th century it is stated that the old Norsemen tried in vain to raise barley.

Population.—The Eskimo population of Danish Greenland (west coast) seems to have decreased since the Norwegians came to the country a century and a half ago. Hans Egede estimated the population then at 30,000, but this is probably a large over-estimate. The decrease may chiefly have been due to infectious diseases, especially a very severe epidemic of smallpox. During the last half of the 19th century there was on the whole a slight increase of the native population: in 1855 it was 9648; in 1870, 9615; in 1881, 9701; in 1883, 9844; in 1885, 9914; in 1888, 10,221; in 1890, 10,254; in 1895, 10,639; and in 1899, 10,974. The population fluctuates a good deal owing, to some extent, to an emigration of natives from the east to the west coast.[1] The population of the east coast seems on the whole to be decreasing. In the north part of the east coast, in the region of Scoresby Fjord and Franz Josef Fjord, numerous ruins of Eskimo settlements are found, and in 1823 Sabine met Eskimo there, but now they have either completely died out or have wandered south. In the district of Angmagssalik the population in 1884 was 413 natives, and on the east coast between Angmagssalik and Cape Farewell there were 135, the population of the east coast being altogether 548 in 1884.[2] In 1892 the population of the Angmagssalik district was only 293, a decrease of 120 since 1884, which is chiefly owing to the fact that a great number of natives (118) had travelled farther south. In 1894[3] the number had decreased to 247, this decrease being chiefly due to an epidemic of influenza. In 1895 also the population numbered 247, while in 1896 it increased to 372, chiefly owing to 118 individuals having come from the south.[4] On 31st December 1899 the population numbered 403. The little tribe of Eskimo living in the region of Cape York near Smith Sound—the so-called "Arctic Highlanders" or Smith Sound Eskimo—numbered in 1895, 253. In 1896 this number was reduced to 229 by an epidemic of influenza. In 1897 the number was 234.[5]

Trade.—The chief addition to trading districts since 1880 was made in 1894, when a new trading and missionary station or "coloni" was established in Angmagssalik on the east coast, where a missionary and a "colonibestyrer," or superintendent of the district, with their families reside. The trade of Greenland has on the whole much decreased during late years, and trading and missions now cost the Danish State a comparatively large sum (about £11,000 every year), although this is partly covered by the income from the cryolite royalty of the mines at Ivigtut. The Danish Mission[6] in Greenland has a yearly grant from the Greenland trade of 36,000 kroner (£2000), besides a contribution of 16,000 kroner (£880) from the Danish State. If these sums be considered, the results of the Greenland trade and missions of late years are the following, according to Mr C. Ryberg, of the Greenland directorate: 1895–96, *deficiency* 183,699 kroner; 1896–97, *deficiency* 284,024 kroner; 1897–98, *deficiency* 92,420 kroner; 1898–99, *deficiency* 40,430 kroner; 1899–1900, *profit* 20,839 kroner; 1900–1, *deficiency* 106,091 kroner. The mean result of this term of six years is consequently a yearly deficiency of 114,304 kroner (£6350). The decline in the value of the trade, which some years ago was very profitable, has to a great extent been brought about by the fall in the price of seal-oil. The exceptional profit in the year 1899–1900 was chiefly due to the extraordinarily high prices of the skins of the blue fox and polar bear, on account of the Paris Exhibition. It might be expected that there should be a decrease in the Greenland seal fisheries, caused by the European and American sealers catching larger quantities every year, especially along the coasts of Newfoundland and Labrador, and so actually diminishing the number of the animals in the Greenland seas. The statistics of South Greenland, however, do not seem to demonstrate any such decrease. For North Greenland there is no information at hand for the later years. According to Mr C. Ryberg, there were, in the seventeen years from 1874 to 1890, 32,826 seals caught yearly in South Greenland. In the following years there were caught in the same district: 1891–92, 24,583 seals; 1892–93, 33,338 seals; 1893–94, 29,726 seals; 1894–95, 38,075 seals; 1895–96, 29,964 seals; and in 1896–97, 41,912. The mean number of seals caught yearly during this period was consequently 32,933 seals, or very nearly the same as during the previous seventeen years.

For further information about Greenland see especially *Meddelelser om Grönland*, Parts i.–xxiii. (Copenhagen, 1879–99); it is chiefly written in Danish, but each part has a summary in French. In Part xiii. there is a complete list of literature about Greenland up to 1880. The more important literature of later years has already been cited in the footnotes. As to the discovery of Greenland by the Norsemen and its early history see KONRAD MAURER'S excellent paper in the report of *Die zweite Deutsche Nordpol Expedition*, 1869–70, vol. ii.—G. STORM. *Studies on the "Vineland" Voyages.* Christiania and Copenhagen, 1889 (see also *Aarbog for Nordisk Oldkyndighed og Historie.* Copenhagen, 1888).—K. J. V. STEENSTRUP. Greenock, a seaport town and parliamentary burgh of Renfrewshire, Scotland, on the south bank of the river Clyde, 21½ miles west-north-west of Glasgow by water, 23 miles by rail. Public erections since 1880 are the municipal chambers, in the Renaissance style, completed in 1886 at a cost of £225,000; Established, Roman Catholic (1900), Reformed Presbyterian, and two United Free churches, a technical college (1900), an eye infirmary, a new post office (1899), a masonic temple, and electric lighting works. Smithston poorhouse and lunatic asylum, which cost £100,000, was erected in 1879. Street tramways connect the town with both Gourock and Port Glasgow. Shipbuilding alone now stands out prominently above other industries; 43,358 tons were launched in 1889, and 41,654 in 1899. Sugar-refining has declined, and in 1900 there were only four refineries at work. Among other industries are boiler and engine making, and an aluminium factory was established in 1898. The dock and quay accommodation now covers 100 acres, and £1,500,000 has been spent on the harbour from first to last. The James Watt dock cost £650,000 in 1886; it is 2000 by 400 feet, and has a depth of 32 feet at low water. Two large tidal harbours cost £500,000. Indeed, the harbour had been improved more

[6] The Moravian Mission, which had worked in Greenland a century and a half, finally retired from the country in 1900.

rapidly and more expensively than the trade of the port warranted, and in 1887 the trustees found themselves unable to pay the interest on the mortgage bonds. At the end of 1898 there were 267 vessels of 273,954 tons on the register of the port. In 1888, 6630 vessels of 1,379,616 tons entered, and 6903 vessels of 1,528,164 tons cleared. In 1898, 9533 vessels of 1,685,235 tons entered, and 9627 vessels of 1,887,565 tons cleared. The value of the foreign and colonial imports was £3,170,328 in 1888, and £1,341,908 in 1898; of the exports, £225,747 in 1888, and £191,261 in 1898. Fort Matilda, with submarine mines, protects the river at Greenock. The School Board manages an academy. Other educational institutions are a school of art and a school of navigation and engineering. Population (1881), 66,704; (1901), 67,645.

Greensboro, capital of Guilford county, North Carolina, U.S.A., at an altitude of 837 feet. It is on the Southern and the Cape Fear and Yadkin Valley railways. It has cotton and flour mills and blast furnaces. Several minor educational institutions are situated here. The name comes from General Greene, who in 1781 defeated the British under Cornwallis at Guilford Court House, near this place. Population (1880), 2105; (1890), 3317; (1900), 10,035, of whom 90 were foreign-born and 4086 negroes.

Greensburg, capital of Westmoreland county, Pennsylvania, U.S.A., at an altitude of 1091 feet, on the Pennsylvania Railway. It has manufactures of iron and glass. Population (1890), 4202; (1900), 6508, of whom 484 were foreign-born and 128 negroes.

Greenville, capital of Washington county, Mississippi, U.S.A., on the eastern bank of the Mississippi river, in the Yazoo Bottom, at an altitude of 125 feet, on the Southern and Yazoo and Mississippi Valley railways. It is in one of the richest cotton regions of the South, and has a large cotton trade. Population (1880), 2191; (1890), 6658; (1900), 7642, of whom 249 were foreign-born and 4987 negroes.

Greenville, capital of Greenville county, South Carolina, U.S.A., at an altitude of 976 feet, on the Southern and the Charleston and Western Carolina railways. It is in the cotton belt, and handles the crop of an extensive surrounding country. It has some manufactures, especially of cotton goods. It is the seat of Furman University and two colleges for women. Population (1880), 6160; (1890), 8607; (1900), 11,860, of whom 119 were foreign-born and 5414 negroes.

Greenville, capital of Hunt county, Texas, U.S.A., at an altitude of 552 feet. It is at the intersection of the Missouri, Kansas, and Texas, the Houston and South-Western, the Sherman, Shreveport, and Southern, and the Texas Midland railways. It is an important shipping point for cotton, and the seat of Burleson College, a Baptist institution, opened in 1893. Population (1890), 4330; (1900), 6860, of whom 114 were foreign-born and 1751 negroes.

Greenwich, a municipal and parliamentary borough of England, on the south bank of the Thames, 4 miles E.S.E. of St Paul's, London, on the South-Eastern and Chatham Railway. A new building for the Royal Observatory was completed in 1899. About a quarter of a mile to the east is the magnetic pavilion, placed thus far away to avoid the disturbance which would be occasioned by the iron used in the principal building. The Government whitebait dinner was resumed in 1895, after an interval of fifteen years. A stained glass window to the memory of General Wolfe was placed in the parish church in 1896. By the London Government Act of 1899 the borough of Greenwich was taken out of the county of Kent and made one of the twenty-eight metropolitan boroughs of the county of London. Population of the metropolitan borough (1891), 78,514; (1901), 95,770.

Greenwich, a town of Fairfield county, Connecticut, U.S.A., with an area of 49 square miles of hill country, and containing a borough of the same name. Greenwich borough is on Long Island Sound, and on the New York, New Haven, and Hartford Railway. It is a popular summer resort, especially for New York business men. Population of the town (1880), 7892; (1890), 10,131; (1900), 12,172, of whom 3271 were foreign-born and 356 negroes.

Greg, William Rathbone (1809–1881), English essayist, the son of a merchant, was born at Manchester in 1809. He became a manufacturer, and entering with ardour into the struggle for free trade, obtained in 1842 the Anti-Corn Law League's prize for the best essay on "Agriculture and the Corn Laws." He was too much occupied with political, economical, and theological speculations to give undivided attention to his business, which became unprosperous, and was relinquished in 1850. Greg turned vigorously to authorship; his *Creed of Christendom* was published in 1851, and in 1852 he contributed no fewer than twelve articles to four leading quarterlies. Disraeli spoke of him eulogistically; Sir George Cornewall Lewis bestowed a Commissionership of Customs upon him in 1856; and in 1864 he was made Comptroller of the Stationery Office. He continued to write, and besides contributions to periodicals produced several volumes of essays on political and social philosophy. The general spirit of these is indicated by the titles of two of the most celebrated, *The Enigmas of Life* (1872) and *Rocks Ahead* (1874). They represent a reaction from the high hopes of the author's youth, when wise legislation was assumed to be a remedy for every public ill. Greg in old age went into the opposite extreme; but his accuracy of thought and deep moral earnestness were always valuable. He died at Wimbledon on the 15th of November 1881.

Gregorovius, Ferdinand (1821 - 1891), German historian and miscellaneous writer, was born at Neidenburg, East Prussia, on the 19th of January 1821. He studied theology and philosophy at Königsberg University, being intended for the priesthood, but relinquished that project and devoted himself to literary work, his first important publication being a study of Goethe's *Wilhelm Meister*. In 1852 he travelled, by way of Corsica, to Italy, and the result was a brilliant book (1857) entitled *Wanderjahre in Italien*, besides a volume on Corsica. He settled at Rome, and between 1859 and 1872 produced his *magnum opus*, the *History of Rome in the Middle Ages*, a work steeped in mediæval learning. Gregorovius was a voluminous writer, and his list of publications is a long one, including a tragedy, *The Death of Tiberias*, an epic, *Euphorion* (1858), and *Athens in the Middle Ages*, the last a historical work which resulted from his travels in Greece and the East in 1880. He died at Munich, 1st May 1891.

Greifswald, a town of Prussia, province of Pomerania, near the head of Greifswald Bay on the Baltic, on which, 2½ miles distant, are the little seaside resorts of Wieck (population 800), which is also the port for Greifswald, and Eldena (1050). In front of the university, which had 808 students and 95 professors in 1900, stands a monument commemorative of its four hundredth anniversary. The university institutions embrace a zoological museum, a gynæcological institute, an ophthalmological school, a psychological school, physical, physiological, and

pharmaceutical institutes, a botanical garden, and (at Eldena) an agricultural school. Population (1885), 20,345; (1900), 22,940.

Greiz, a town of Germany, capital of the principality of Reuss the Elder, on the White Elster, 66 miles by rail south from Leipzig. It consists of two parts, the old town on the right bank, and the new town on the left bank, rapidly growing and regularly laid out. There are monuments to the Emperor William I. (1888), Bismarck (1895), and the war of 1870–71. Population (1885), 17,288; (1900), 22,345.

Grenada, since 1885 the seat of government of the Windward Islands, and the most southerly of the group, situated about 90° N. of Trinidad, between 11° 58′ and 12° 30′ N. lat. and 61° 20′ and 61° 35′ W. long. It is about 21 miles long by 12 miles broad, with an area of 133 square miles. The island is very mountainous, and the hills (the highest of which, Mount Catherine, is 2749 feet), running off in spurs from the centre, form valleys of great beauty and fertility. Included in the government of the Windward Islands are also a number of small islands called GRENADINES, some of which are attached to the local government of St Vincent and some to that of Grenada. Of the latter the chief is Carriacou, with an area of nearly 7000 acres and a population of over 6000. Population of Grenada (1877), 41,355; (1899), 64,098. The birth-rate per 1000 of the mean estimated population was 42·17, and the death-rate 20·85. The climate is very healthy, epidemic diseases are rare, and the temperature is equable. The hottest months are August, September, and October. The mean temperature of 1898 at 500 feet above the sea was 79·0° at 9 A.M. The rainfall is very heavy, amounting in some parts to 200 inches a year. During 1898 it was 162·45 inches in the centre of Grenada and 80·28 at Carriacou. The rain lasts, on and off, from May to the end of the year, September and November being especially wet. The island is singularly free from the visitations of hurricanes. It is a favourite health resort for the neighbouring colony of Trinidad. A new sanatorium was opened at Grand Etang (1800 feet) in 1899. There are practically no Crown lands for disposal. Good roads and by-ways intersect the island in every direction. The value of imports in 1877 was £127,204; in 1899 it was £226,828. The value of exports in 1877 was £145,906; in 1899 it was £267,738. The imports were derived as follows:—United Kingdom, £101,921; British colonies, £64,603; foreign countries (mainly United States), £60,303. The exports go in the following proportions:—To the United Kingdom, 94 per cent.; to the British colonies, 1 per cent.; to foreign countries (principally the United States), 4 per cent. The chief articles of export in 1898 were cacao (£234,610) and spices (£21,761), with smaller values of cotton, live stock, kola nuts, coffee, and logwood, the sugar-cane being now chiefly prepared for local consumption as sugar, molasses, or rum. An excellent oyster is obtained at Carriacou, and turtle and fresh fish are plentiful. The revenue in 1877 was £29,084; in 1899 it was £68,757. The expenditure in 1877 was £29,581; in 1899 it was £59,358. The tonnage of vessels entered in 1898 was 216,192, of which 209,455 was British and 6737 foreign. There is no military force, but there is a police force of sixty-five officers and men. The elementary schools were in 1899 partly Government (9) and partly grant-in-aid schools (32) under the management of the ministers of the different religious denominations (Roman Catholics, 19; Anglican, 7; Wesleyan, 4; Church of Scotland, 2), the whole being under a Board of Education nominated by the governor. The 41 schools had 9240 pupils on the roll, with an average daily attendance of about 52 per cent. There are a grammar-school for boys and two high schools for girls in St George (the capital) receiving grants-in-aid. The bishopric of the Windward Islands forms part of the West Indian province of the Church of England. English is universally spoken, but the peasantry speak amongst themselves a French patois, a legacy of French occupation. The Legislative Council consists of the governor with six official and seven unofficial members, all nominated by the crown. (F. CU.)

Grenadier.—Grenadiers were soldiers, part of whose duty it was to throw hand-grenades. Du Bellay says grenades were made in large numbers at Arles in 1536. The Comte de Rendan was killed by one at the siege of Rouen, 1562. They were used at the siege of Famagusta in Cyprus, 1571. Four or five grenadiers were attached to each French company in 1667, and in 1670 they were increased and formed in companies. Evelyn tells us in his *Diary* that, on 29th June 1678, he saw at the Hounslow camp certain soldiers "called granadiers, who were dexterous in flinging hand-granades." Eventually each English battalion had a company.

Two excellent plates of grenadiers of the 2nd Regiment of Foot (Royal West Surrey), 1714–27, taken from picture-board dummies in the County Hotel, Carlisle, will be found in the *Archæological Journal*, xlvii. 321, 324. The same journal, xxiii. 222, gives a plate, "Blow your Match," after a sketch by Lens, "limner to His Majesty" George II., which represents a grenadier of the 1st Regiment of the Guards in 1735, grenade in hand.

Grenoble, chief town of department Isère, France, 393 miles south-east of Paris, on the railway from Paris to Marseilles, at the confluence of the Drac with the Isère. The city is extending in the direction of the Drac, and in the north-east, enclosed by a bend of the Isère, is the peninsula of Île Verte, a rapidly growing suburb. The lycée was opened in 1886. There are several monuments, among them one (1890) commemorating the commencement of the Revolution in Dauphiné. Grenoble is the head-quarters of the 14th Army Corps, is the seat of a Court of Appeal, and has a chamber and a tribunal of commerce, and an assay office. Notwithstanding the application of machinery to many of the processes employed in the glove manufacture, and the consequent reduction of manual labour, the number of the persons engaged in the trade has been more than maintained. Some 4000 men and 21,000 women and children produce annually about 1,200,000 dozen pairs of gloves, valued at from £1,400,000 to £1,440,000. There is a large establishment employing about 360 workpeople in the manufacture of metal buttons, &c. As much as 1,540,000 ℔ of copper are used in a year, yielding daily about 1,500,000 button pieces, the finished product being 8000 buttons daily. This factory not only supplies buttons for the Grenoble industry, and for export to other glove manufacturing centres, but also the principal machines required in the making of gloves. Other manufactures are silk and linen, hosiery, heavy iron goods, alimentary paste, artificial flowers, and mosaics, and there are coal mines and quarries. Population (1881), 41,154; (1901), 68,052.

Grévy, François Paul Jules (1807–1891), third President of the French Republic, was born at Mont-sous-Vaudrey in the Jura, on 15th August 1807. He became an advocate in 1837, and, having steadily maintained republican principles under the Orleans monarchy, was elected by his native department to the Constituent Assembly of 1848. Foreseeing that Louis Bonaparte would be elected president by the people, he proposed to vest the chief authority in a president of the Council elected and removable by the Assembly. After the *coup d'état* this proposition gained M. Grévy a reputation for sagacity,

and upon his return to public life in 1869 he took a prominent place. After the fall of the Empire he was chosen president of the Assembly on the 16th of February 1871, and occupied this position till the 2nd of April 1876, when he resigned on a question of discipline. On the 8th of March 1876 he was elected president of the Chamber of Deputies, a post which he filled with such efficiency that upon the resignation of Marshal MacMahon he seemed to step naturally into the Presidency of the Republic (30th January 1879). Quiet, shrewd, attentive to the public interest and his own, but without any particular distinction, he would have left an unblemished reputation if he had not unfortunately accepted a second term (18th December 1885). Shortly afterwards the traffic of his son-in-law (M. Wilson) in the decorations of the Legion of Honour came to light. M. Grévy was not accused of personal participation in these scandals, but he was somewhat obstinate in refusing to realize that he was responsible indirectly for the use which his relative had made of the Elysée, and it had to be unpleasantly impressed upon him that his resignation was inevitable (2nd December 1887). He died at Mont-sous-Vaudrey, 9th September 1891. He owed both his success and his failure to the completeness with which he represented the particular type of the thrifty, generally sensible and patriotic, but narrow-minded and frequently egoistic bourgeois. (See also FRANCE, *History*.)

Grey, Sir George (1812–1898), British colonial governor and statesman, only son of Lieutenant-Colonel Grey of the 30th Foot, was born in Lisbon on 14th April 1812, eight days after the death of his father at the storming of Badajoz. He passed through Sandhurst with credit, and received his commission in 1829. His lieutenancy was dated 1833, and his captaincy 1839, in which year he sold out and left the army. In the early 'thirties he was quartered in Ireland, where the wretchedness of the poorer classes left a deep impression on his mind. In 1836 the Royal Geographical Society accepted his offer to explore the north-west region of West Australia, and accordingly he landed at Hanover Bay at the end of 1837. The surrounding country he found broken and difficult, and his hardships were aggravated by the tropical heat and his ignorance of the continent. In a skirmish with the natives, in which he was speared near the hip, he showed great courage, and put the assailants to flight, shooting the chief, who had wounded him. After a brave endeavour to continue his journey his wound forced him to retreat to the coast, whence he sailed to Mauritius to recruit. Next year he again essayed exploration, this time on the coast to the north and south of Shark's Bay. He had three whale-boats and an ample supply of provisions, but by a series of disasters his stores were spoilt by storms, his boats wrecked in the surf, and the party had to tramp on foot from Gantheaume Bay to Perth, where Grey, in the end, walked in alone, so changed by suffering that friends did not know him. In 1839 he was appointed Governor-Resident at Albany, and during his stay there married Harriett, daughter of Admiral Spencer, and also prepared for publication an account, in two volumes, of his expeditions. In 1840 he returned to England, to be immediately appointed by Lord John Russell to succeed Colonel Gawler as Governor of South Australia. Reaching the colony in May 1841, he found it in the depths of a depression caused by mismanagement and insane land speculation. By rigorously reducing public expenditure, and forcing the settlers to quit the town and betake themselves to tilling their lands, and with the opportune help of valuable copper discoveries, Grey was able to aid the infant colony to emerge from the slough. So striking were his energy and determination that when, in 1845, the little settlements in New Zealand were found to be involved in a native war, and on the verge of ruin, he was sent to save them. The Maori chiefs in open rebellion were defeated, and made their submission. Another powerful leader suspected of fomenting discontent was arrested, and friendly chieftains were subsidized and honoured. Bands of the natives were employed in making government roads, and were paid good wages. The governor gained the veneration of the Maori tribes, in whose welfare he took a close personal interest, and of whose legends and myths he made a valuable and scholarly collection, published in New Zealand in 1855 and reprinted thirty years afterwards. With peace prosperity came to New Zealand, and the Colonial Office desired to give the growing settlements full self-government. Grey, arguing that this would renew war with the Maori, returned the constitution to Downing Street. But though the Colonial Office sustained him, he became involved in harassing disputes with the colonists, who organized an active agitation for autonomy. In the end a second constitution, partly framed by Grey himself, was granted them, and Grey, after eight years of despotic but successful rule, was transferred to Cape Colony. He had been knighted for his services, and had undoubtedly shown strength, dexterity, and humanity in dealing with the whites and natives. In South Africa his success continued. He thwarted a formidable Kaffir rebellion in the East Provinces, and pushed on the work of settlement by bringing out men from the German Legion and providing them with homes. He gained the respect of the British, the confidence of the Boers, the admiration and the trust of the natives. The Dutch of the Free State and the Basutos chose him as arbitrator of their quarrels. When the news of the Indian Mutiny reached Cape Town he strained every nerve to help Lord Canning, despatching men, horses, stores, and £60,000 in specie to Bombay. He persuaded a detachment, then on its way round the Cape as a reinforcement for Lord Elgin in China, to divert its voyage to Calcutta. Finally, in 1859, Grey almost reached what would have been the culminating point of his career by federating South Africa. Persuaded by him, the Orange Free State passed resolutions in favour of this great step, and their action was welcomed by Cape Town. But the Colonial Office disapproved of the change, and when Grey attempted to persevere with it Sir Edward Bulwer Lytton recalled him. A change of Ministry during his voyage to England displaced Sir Edward Bulwer Lytton. But though the Duke of Newcastle reinstated Grey, it was with instructions to let federation drop. In 1861 the Colonial Office sent him, for the fourth time in succession, to take up a post of exceptional difficulty by again entrusting him with the governorship of New Zealand, where an inglorious native war in Taranaki had just been succeeded by an armed truce. Grey did his best to make terms with the rebels and to re-establish friendship with the Maori king and the land league of tribes formed to stop further sales of land to the whites. But the Maori had got guns and powder, and were suspicious and truculent. In vain Grey, supported by Bishop Selwyn and by Fox and the peace party among the settlers, strove to avert war. It came in 1863, and spread from province to province. Ten thousand regulars and as many colonial riflemen were employed to put it down. The imperial troops were badly handled, and Grey, losing patience, became involved in bitter disputes with their commanders, Generals Cameron and Tuke. As an example to the former he himself attacked and captured Weraroa, the strongest of the Maori stockades, with a handful of militia,

a feat which delighted the colonists, but made him as much disliked at the War Office as he now was at Downing Street. Moreover, Grey had no longer real control over the islands. New Zealand had become a self-governing colony, and though he vindicated the colonists generally when libellous imputations of cruelty and land-grabbing were freely made against them in London, he crossed swords with his ministers when the latter confiscated three million acres of tribal land belonging to the insurgent Maori. Yet through all these troubles progress was made; many successes were gained in 1866, chiefly by the colonial militia, and a condition of something like tranquillity had been reached in 1867, when he received a curt intimation from the Duke of Buckingham that he was about to be superseded. The colonists, who believed he was sacrificed for upholding their interests and good name, bade farewell to him in 1868 in an outburst of gratitude and sympathy; but his career as a servant of the empire was at an end. Returning to England, he tried to enter public life, delivered many able speeches advocating what later came to be termed Imperialism, and stood for Newark. Discouraged, however, by the official Liberals, he withdrew and turned again to New Zealand. In 1872 he was given a pension of £1000 a year, and settled down on the island of Kawau, not far from Auckland, which he bought, and where he passed his leisure in planting, gardening, and collecting books. In 1875, on the invitation of the Auckland settlers, he became superintendent of their province, and entered the New Zealand House of Representatives to resist the abolition of the provincial councils of the colony, a change then being urged on by Sir Julius Vogel in alliance with the Centralist Party. In this he failed, but his eloquence and courage drew round him a strong Radical following, and gave him the Premiership in 1877. Manhood suffrage, triennial parliaments, a land-tax, the purchase of large estates, and the popular election of the governor, were leading points of his policy. All these reforms, except the last, he lived to see carried; none of them were passed by him. A commercial depression in 1879 shook his popularity, and on the fall of his Ministry in 1879 he was deposed, and for the next fifteen years remained a solitary and pathetic figure in the New Zealand Parliament, respectfully treated, courteously listened to, but never again invited to lead. In 1891 he came before Australia as one of the New Zealand delegates to the Federal Convention at Sydney, and characteristically made his mark by standing out almost alone for "one man one vote" as the Federal franchise. This point he carried, and the Australians thronged to hear him, so that his visits to Victoria and South Australia were personal triumphs. When, too, in 1894, he quitted New Zealand for London, some reparation was at last made him by the Imperial Government; he was called to the Privy Council, and graciously received by Queen Victoria on his visit to Windsor. Thereafter he lived in London, and died on the 20th of September 1898. He was given a public funeral at St Paul's. Grey was all his life a collector of books and manuscripts. After leaving Cape Colony, he gave his library to Cape Town in 1862; his subsequent collection, which numbered 12,000 volumes, he presented to the citizens of Auckland in 1887. In gratitude, the people of Cape Town erected a statue of him opposite their library building. (W. P. R.)

Grey, Henry Grey, 3rd Earl (1802–1894), English statesman, born 28th December 1802, was the fifth son of the Earl Grey who was prime minister at the time of the Reform Bill of 1832. He entered Parliament in 1826 under the title of Viscount Howick as member for Winchilsea, which constituency he left in 1831 for Northumberland. On the accession of the Whigs to power in 1830 he was made Under-Secretary for the Colonies, and laid the foundation of his intimate acquaintance with colonial questions. He belonged at the time to the more advanced party of colonial reformers, sharing the views of Edward Gibbon Wakefield on questions of land and emigration, and resigned in 1834 from dissatisfaction that slave emancipation was made gradual instead of immediate. In 1835 he entered Lord Melbourne's Cabinet as Secretary at War, and effected some valuable administrative reforms, especially by suppressing malpractices detrimental to the troops in India. After the partial reconstruction of the ministry in 1839 he again resigned, disapproving of the more advanced views of some of his colleagues. These repeated resignations gave him a reputation for crotchetiness, which he did not decrease by his disposition to embarrass his old colleagues by his action on Free Trade questions in the session of 1841. During the exile of the Liberals from power he went still farther on the path of Free Trade, and anticipated Lord John Russell's declaration against the Corn Laws. When, on Sir Robert Peel's resignation in December 1845, Lord John Russell was called upon to form a ministry, Howick, who had become Earl Grey by the death of his father in the preceding July, refused to enter the new Cabinet if Lord Palmerston were Foreign Secretary. He was greatly censured for perverseness, and particularly when in the following July he accepted Lord Palmerston as a colleague without remonstrance. His conduct, nevertheless, afforded Lord John Russell an escape from an embarrassing situation. Becoming Colonial Secretary in 1846, he found himself everywhere confronted with arduous problems, which in the main he encountered with success. His administration formed an epoch. He was the first minister to proclaim that the colonies were to be governed for their own benefit and not for the mother-country's; the first systematically to accord them self-government so far as then seemed possible; the first to introduce free trade into their relations with Great Britain and Ireland. The concession by which colonies were allowed to tax imports from the mother-country *ad libitum* was not his; he protested against it, but was overruled. In the West Indies he suppressed, if he could not overcome, discontent; in Ceylon he put down rebellion; in New Zealand he suspended the constitution he had himself accorded, and yielded everything into the masterful hands of Sir George Grey. The least successful part of his administration was his treatment of the convict question at the Cape of Good Hope, which seemed an exception to his rule that the colonies were to be governed for their own benefit and in accordance with their own wishes, and subjected him to a humiliating defeat. After his retirement he wrote a history and defence of his colonial policy in the form of letters to Lord John Russell, a dry but instructive book. He resigned with his colleagues in 1852. No room was found for him in the Coalition Cabinet of 1853, and although during the Crimean struggle public opinion pointed to him as the fittest man as Minister for War, he never again held office. During the remainder of his long life he exercised a vigilant criticism on public affairs. In 1858 he wrote a work (republished in 1864) on parliamentary reform; in 1888 he wrote another on the state of Ireland; and in 1892 one on the United States tariff. In his latter years he was a frequent contributor of weighty letters to *The Times* on land, tithes, currency, and other public questions. His principal parliamentary appearances were when he moved for a committee on Irish affairs in 1866, and when in 1878 he passionately opposed the policy of the Beaconsfield Cabinet in India.

He nevertheless supported Lord Beaconsfield at the dissolution, regarding Mr Gladstone's accession to power with much greater alarm. He was a determined opponent of Mr Gladstone's Home Rule policy. He died on 9th October 1894. None ever doubted his capacity or his conscientiousness, but he was generally deemed impracticable and disagreeable. Prince Albert, however, who expressed himself as ready to subscribe to all Grey's principles, and applauded him for having principles, told Stockmar that, although dogmatic, he was amenable to argument; and Sir Henry Taylor credits him with "more freedom from littlenesses of feeling than I have met before in any public man." His chief defect was perceived and expressed by his original tutor and subsequent adversary in colonial affairs, Edward Gibbon Wakefield, who wrote, "With more than a common talent for understanding principles, he has no originality of thought, which compels him to take all his ideas from somebody; and no power of working out theory in practice, which compels him to be always in somebody's hands as respects decision and action." (R. G.)

Grieg, Edvard Hagerup (1843-——), Norwegian musical composer, was born at Bergen, 15th June 1843. In spite of the fact that his family was of Scottish origin, Alexander Greig (*sic*) and his wife having emigrated from Fraserburgh to Norway more than a century ago, Grieg is the foremost and most typical representative of Scandinavian music. After the completion of his musical studies at the Leipzig Conservatorium, whither he went on the advice of Ole Bull, and where he passed, like all his contemporaries, under the influence of the Mendelssohn and Schumann school of romantics, he studied for a short time with Gade and Emil Hartmann in Copenhagen. Together with another young Norwegian composer, Richard Nordraak, Grieg made a kind of crusade in favour of national music, and even his earliest works show his strong affinity for a style built upon the tradition ballads of his country. He visited Italy in 1865 and 1870, and from 1867 till 1880 conducted a musical union in Christiania. More recently he has appeared in the capital as an orchestral conductor, but the greater part of his life has been spent at Bergen. In 1888 he played his pianoforte concerto and conducted his "two melodies for strings" at a Philharmonic Concert in London, and visited England again in 1891, 1894, and 1896, receiving the degree of Mus.D. from the University of Cambridge in 1894. His works include a large number of songs, and pianoforte solos of "lyrical" form; three violin sonatas; a string quartet; a sonata for piano and violoncello; *Aus Holberg's Zeit;* a suite for stringed orchestra, and also for pianoforte solo; the pianoforte concerto already mentioned; a concert-overture, *Im Herbst*, and other smaller pieces for orchestra; and several works for chorus and orchestra, with or without solos. His incidental music to Ibsen's *Peer Gynt* is widely known through the two suites selected from it, the first of which was originally published as a duet for pianoforte, and afterwards scored for full orchestra. Grieg has enshrined the characteristics of Scandinavian music in works of undying beauty, though for the most part of somewhat small calibre. In the use of these elements he departs very far from the recognized rules of form, and he has always succeeded best in the class of compositions where such departure is most readily excused. His songs may be said to be always the more spontaneous the more closely they conform to the simple model of the volkslied; the pianoforte concerto is brilliant and spontaneous, and the first and second of his violin sonatas are perennially agreeable, so free and artless is the flow of their melody. In his numerous piano pieces and in those of his songs where a definitely national style of treatment is avoided, the impression made is less permanent, for, apart from the national characteristics which he employs so adroitly, his individuality is not strongly pronounced, and in the rare cases where he has attempted the treatment of subjects not specially national in type on the conventional lines, he has shown himself somewhat of a mannerist.

Griffin, capital of Spalding county, Georgia, U.S.A., 43 miles south of Atlanta, on the Southern and the Central of Georgia railways, at an altitude of 975 feet. It has cotton factories and a large cotton trade. Population (1880), 3620; (1890), 4503; (1900), 6857, of whom 25 were foreign-born and 3258 negroes.

Grimsby, Great, a parliamentary, county, and municipal borough, mercantile and fishing seaport of England, in the county of Lincoln, situated on the east coast, near the mouth of the Humber, and 155 miles north by east from London by the Great Northern Railway. It also has a station on the Great Central Railway. The port possesses five docks (104 acres) and three graving docks. These are reached through a tidal basin of 15 acres, protected on the east and west by breakwaters. The weight of fish sent from Grimsby by rail increased from 26,324 tons in 1870 to 114,292 tons in 1899. In 1899 the fishing fleet consisted of 522 vessels, mostly steam trawlers, of 31,512 tons, manned by nearly 4650 hands. In 1900 the mercantile fleet belonging to the port numbered 622 vessels of 50,540 tons. The value of the imports increased from £3,544,449 in 1881 to £7,957,414 in 1900; that of the exports from £7,342,458 in 1881 to £11,007,937 in 1900. The most important items amongst the imports are butter, woollens, timber, cereals, eggs, glass, cottons, preserved meat, wool, sugar, and bacon. The exports consist chiefly of woollen yarn, woollens, cotton goods, cotton yarn, machinery, &c., and coal. The port was cleared by 926 vessels of 416,651 tons in 1885, and by 1748 of 960,236 tons in 1899. There is in addition a coasting trade of some 500,000 tons annually. To the industries must be added the manufacture of ship tackle, ropes, ice, turnery, flour, linseed cake, artificial manure, and sawmills, bone and corn mills, and creosote works. The church of St John the Divine was built, in the Early English style, in 1892; the church of All Saints' in 1891; St Barnabas's in 1900; St Paul's in 1884; the Roman Catholic church in 1883; the Sailors' and Fishermen's Harbour of Refuge in 1890; and the Grimsby, Cleethorpes, and East Coast Orphan Home in 1892. The church of St James's was restored between 1882 and 1885. The Wesleyans and Congregationalists have also built new chapels. In 1899–1900 the Mechanics' Institution was converted into the Free Public Library. The Constitutional Club dates from 1892. The Duke of York public gardens were opened in 1894, and a new cemetery in 1889. There has been a technical school since 1893. The sewage works, with a pumping station, were completed in 1895. In 1889 Grimsby was extended by the inclusion of part of the township of Clee with Weelsby, and in 1891 was made a county borough, with a separate court of quarter sessions. It is governed by a mayor, 12 aldermen, and 36 councillors, and is represented in Parliament by one member. Area, 2832 acres. Population (1891), 51,934; (1901), 63,138. Birth-rate, 30·0 (1898); death-rate, 15·9 (1898). The second half of the year 1901 was marked by a serious wages dispute between the owners and crews of the fishing-vessels of the port, which was eventually settled by the intervention of the Board of Trade and an arbi tration before Sir Edward Fry.

Grimthorpe, Edmund Beckett, 1st Baron (1816- ——), son of Sir Edmund Beckett Denison, was born 12th May 1816. He was educated at Doncaster and Eton, whence he proceeded to Trinity College, Cambridge, and graduated thirtieth wrangler in 1838. Having adopted the law as his profession, he was called to the bar at Lincoln's Inn, 1841. Upon succeeding to the baronetcy in 1874 he dropped the name of Denison, which his father had assumed in 1816. From 1877 to 1900 he was chancellor and vicar-general of York, and he was raised to the peerage in 1886. He was made a Q.C. in 1854, and was for many years a leader of the Parliamentary Bar. He devoted himself to the study of astronomy, horology, and architecture, more especially Gothic ecclesiastical architecture. As early as 1850 he had become a recognized authority on clocks, watches, and bells, and in particular on the construction of turret clocks, for it was well known that he had designed Dent's Great Exhibition clock, and his *Rudimentary Treatise* was a notable book that went through many editions. It was therefore natural that in 1851 he should be called upon, in conjunction with the Astronomer Royal (Mr, afterwards Sir, G. B. Airy) and Mr Dent, to design a suitable clock for the new Houses of Parliament. The present clock, "Big Ben," was the result. In every burning question during his time, such as marriage with a deceased wife's sister, the revision of the New Testament, or the views of Huxley and the modern school on miracles, Lord Grimthorpe took a prominent part, either in the form of pamphlets or of letters to *The Times*. It is, however, in connexion with the restoration of St Albans Abbey that he is most widely known. The St Albans Abbey Reparation Committee, which had been in existence since 1871, and for which Sir Gilbert Scott had carried out some admirable repairs, obtained a faculty from the Diocesan Court in 1877 to repair and restore the church and fit it for cathedral and parochial services. Very soon, however, the committee found itself deeply involved and unable to raise the necessary funds, and it was at this juncture that a new faculty was granted to Lord Grimthorpe (then Sir Edmund Beckett) to "restore, repair, and refit" the abbey at his own expense. Lord Grimthorpe made it an express stipulation that the work should be done according to his own designs and under his own supervision. Lord Grimthorpe's public spirit in undertaking the burden of the work was undeniable, but his treatment of the roof, the new west front, and the windows inserted in the terminations of the transepts, excited a storm of adverse criticism and was the subject of vigorous protests from the professional architectural world.

Grindelwald, a valley in the Bernese Oberland in Switzerland, and one of the chief resorts of tourists in Switzerland. It is shut in on the south by the precipices of the Wetterhorn, Mettenberg, and Eiger, between which flow two famous glaciers. On the north it is sheltered by the Faulhorn range, while on the east the Great Scheidegg Pass leads over to Meiringen, and on the south-west the Little Scheidegg or Wengern Alp (railway 11¼ miles across) divides it from Lauterbrunnen. The main village is connected with Interlaken by a cog-wheel railway (12½ miles). The valley is very green, and possesses excellent pastures, as well as fruit trees, though but little corn is grown. It is watered by the Black Lütschine, a tributary of the Aar. The height of the church above the sea-level is 3468 feet. The population in 1900 was 3342, practically all Protestant and German-speaking, and shows a slight increase. The glacier guides are the best in the Alps. The valley was originally inhabited by the serfs of various great lords in summer for the sake of pasturage. A chapel in a cave was superseded in about 1146 by a wooden church, replaced in about 1180 by a stone church, which was pulled down in 1793 to erect the present building. Gradually the Austin canons of Interlaken bought out all the other owners in the valley, but when that house was suppressed in 1528 by the town of Bern the inhabitants gained their freedom. The church hamlet, with the neighbouring houses, bears the name of Gydisdorf. Grindelwald is very much frequented by visitors in winter.

See W. A. B. Coolidge. *Walks and Excursions in the Valley of Grindelwald* (also in French and German). Grindelwald, 1900. —E. F. von Mülinen. *Beiträge zur Heimathkunde des Kantons Bern, deutschen Theils*, vol. i. (Bern, 1879), pp. 24-26.—G. Strasser. *Der Gletschermann*. Grindelwald, 1888-90. Scattered notices may be found in the new edition (London, 1899) of the "General Introduction" (entitled "Hints and Notes for Travellers in the Alps") to Mr John Ball's *Alpine Guide*. (W. A. B. C.)

Grinstead, East, a market-town and railway station in the East Grinstead parliamentary division of Sussex, England, 12 miles west of Tunbridge Wells. St Swithin's church has ancient memorials. There are a literary and scientific institution, a cottage hospital, Sackville College (an almshouse founded in 1608), St Margaret's Home and Orphanage, a Roman Catholic church, and an isolation hospital. Brewing and brick and tile making are carried on. In the vicinity (nearest station, Forest Row) is the golf-course of the Royal Ashdown Forest Golf Club, one of the most beautiful and also one of the most sporting of English inland links. Area of urban district, 6415 acres. Population (1881), 4783; (1901), 6094.

Griqualand. See Kaffraria.

Grisons, or Graubünden, the largest of the Swiss cantons. It has a total area of 2773 square miles. Of this only 1488 square miles are classed as "productive," forests covering no fewer than 490 square miles, and vineyards but 1 square mile. Of the "unproductive" area 139 square miles (more than in any other canton save the Valais) are occupied by glaciers, while a good deal of space is taken up by lakes, though of no great size. The valley of Juf (6998 feet) is the loftiest permanently inhabited village in the entire chain of the Alps. In 1888 the population was 94,810, or 35 inhabitants to each square mile, the lowest rate of density in the whole of Switzerland. In that year the Protestants numbered 51,937, the Roman Catholics 42,797, and the Jews 13. In 1900 the population was 104,510, of whom 48,937 were German-speaking, 38,677 Romónsch- or Ladin-speaking, 13,883 Italian-speaking, and only 535 French-speaking.

The capital of Grisons is Coire or Chur. There are fourteen administrative districts in the canton. The existing cantonal constitution dates from 1892. The legislature (numbers not fixed by the constitution) is elected for two years by a popular vote, by which also the five members of the executive are chosen for three years. For all laws the "obligatory referendum" obtains, while with regard to resolutions and ordinances made by the legislature, 3000 citizens can demand the "facultative referendum." In 1892 the right of "initiative" as to legislative projects was given to 3000 citizens, but 5000 are required in the case of a revision of the cantonal constitution. In 1897 the state revenue of the canton was 1,147,679 francs (a rise of 9½ per cent. since 1885), and the state expenditure 1,935,564 francs (a rise of 20¼ per cent. since 1885). But in these sums the taxes are not reckoned, which always causes a deficit that is carried to the capital account and is met by the land tax—a complicated system. Really there is thus never a deficit, as the amount of the land tax varies annually according to the amount which *must* be covered. This singular system of accounts is quite unique in Switzerland, but is prescribed by the cantonal constitution (Article 19). Apart

from the special loan of 10,000,000 francs for the construction of railways, the public debt in 1897 was 5,992,161 francs. There is a railway up the main Rhine valley to Coire and thence to Thusis, and another from Landquart up to Davos, and others are in construction. Davos-Platz (5115 feet) and St Moritz (6089 feet) are the most famous "air cures" in Grisons. A newer resort is Arosa (6108 feet) in the Schanfigg valley, above Coire.

(W. A. B. C.)

Grivegnée, a town of Belgium, in the province and 3 miles S.E. of the town of Liége. It was in the ironworks of this town that English methods of treating the metal were first introduced into Belgium. Population (1899), 10,565.

Gródek, the chief town of a government district in Galicia, Austria, about 18 miles to the S.W. of Lemberg. It is a station on the railway between the latter town and Cracow. It is an important corn market and centre of the trade in flax, of which large quantities are grown in the district. Population (1890), 10,742; (1900), 11,845 (69 per cent. Polish, 30 per cent. Ruthenian, 1 per cent. German; 36 per cent. Roman Catholic)

Grodno, one of the Lithuanian governments of North-western Russia. It is hilly in the north (highest altitude 924 feet), but otherwise is a vast plain. Granites and gneisses appear on the river Bug; Cretaceous, and especially Tertiary, deposits elsewhere. The soil is mostly sandy, assuming the character of drifting sands in Grodno district and along the rivers; the remainder is of moderate fertility, and in places marshy. Great marshes occur in the Byelovyezhsk and Grodno *pushchas* (forests). Forests cover nearly one-fifth of the total area. Peat-bog, sometimes four to seven feet thick, is widely met with. The climate is wet and cold, the average temperatures at Grodno being for the year, 42° F.; for January, 22°; for July, 73°; the yearly rainfall is 20·5 inches. The population in 1897 numbered 1,617,859 (789,801 women, 255,946 living in towns), and consists of White and Little Russians (54 per cent.), Poles (a little over 20 per cent., chiefly in south-west), and Jews (19 per cent.). The Lithuanians and Tatars proper number but a few thousands each. Agriculture is the main occupation. The peasants own 42 per cent. of the land, *i.e.*, 4,046,900 acres, of which 2,327,400 acres are arable. The crops are moderately good. Cattle-breeding is carried on, there being in 1891 176,245 horses, 484,110 horned cattle, and 685,200 sheep. In respect of woollen cloth factories Grodno occupies in Russia the third place; there are about 150, employing some 4754 persons, with a yearly production of £330,600. Tobacco factories, silk and shoddy mills, and tanneries come next, the total number of factories being 3671, employing over 21,600 persons in 1897, with a yearly return of £1,537,840. There were besides over 25,000 artizans. The annual aggregate tonnage of the navigation in the drainage areas of both the Niemen and the Vistula is 257,450 tons. Grodno is divided into nine districts, the chief towns of which are: Grodno, Brest Litovsk (46,542 inhabitants), Byelsk (7461), Byelostok (63,927), Kobrin (10,365), Pruzhany (7634), Slonim (15,893), Sokolka (7595), and Volkovysk (10,584). GRODNO, capital of the government, is situated on the right bank of the Niemen, which is spanned by an iron bridge, 533 miles S.W. of St Petersburg by rail. It is well provided with secondary schools for boys and girls. Only the tobacco factories are of importance; but there is considerable trade in wood and timber, and various goods are shipped on the Niemen. The population in 1897 was 46,871, of whom nearly two-thirds were Jews.

(P. A. K.)

Groen Van Prinsterer, Guillaume (1801–1876), Dutch politician and historian, was born at Voorburg, near The Hague, on the 21st of August 1801. He studied at Leyden University, and graduated in 1823 both as Doctor of Literature and LL.D. From 1829 to 1833 he acted as secretary to King William I. of Holland, afterwards took a prominent part in Dutch home politics, and gradually became the leader of the so-called anti-revolutionary party, both in the Second Chamber, of which he was for many years a member, and outside. In Groen the doctrines of Guizot and Stahl found an eloquent exponent. They permeate his controversial and political writings and historical studies, of which his *Handbook of Dutch History* (in Dutch) and *Maurice et Barnevelt* (in French, 1875, a criticism of Motley's Life of Van Olden-Barnevelt) are the principal. Groen was violently opposed to Thorbecke, whose principles he denounced as ungodly and revolutionary. Although he lived to see these principles triumph, yet he never ceased to oppose them until his death, which occurred at The Hague on the 19th of May 1876. He is best known as the editor of the *Archives et Correspondance de la Maison d'Orange* (12 vols., 1835–45), a great work of patient erudition, which procured for him the title of the "Dutch Gachard." Mr J. L. Motley acknowledges his indebtedness to Groen's *Archives* in the preface to his *Rise of the Dutch Republic*, at a time when the American historian had not yet made the acquaintance of King William's archivist, and also bore emphatic testimony to Groen's worth as a writer of history in the correspondence published after his death. At the first reception, in 1858, of Mr Motley at the royal palace at The Hague, the King presented him with a copy of Groen's *Archives* as a token of appreciation and admiration of the work done by the "worthy vindicator of William I., Prince of Orange." This copy, bearing the King's autograph inscription, afterwards came into the possession of Sir William Vernon Harcourt, Mr Motley's son-in-law.

(H. Tr.)

Groningen, a province and town in the Netherlands. Clay, and clay and sand mixed, predominate in the north and north-east part of the province, the high fens of the southern portion lying on diluvial sand. The former is an agricultural district, growing wheat and oil-seeds; on the latter cattle are bred, rye, potatoes, and buckwheat grown, peat is cut, and industries and shipping flourish. The area of the province is 904 square miles, and its population in 1900 was 299,033. The town of GRONINGEN is situated 45½ miles east of Harlingen, with which it is connected by rail, at the end of the sandy tongue (the *Hondsrug*) which stretches from the plateau of Drenthe to the clay soil in the centre of the province, while it communicates by rivers and canals with the sea and adjoining provinces. To the advantages of its natural position the town as capital of the province has added those of commercial and political supremacy and monopoly, and this accounts for the fact that the small towns (Winschoten, Appingedam, Delfzijl) of the province are few in number. Considerable trade is done in grain, wood, turf, and cattle with Great Britain, Germany, Scandinavia, and Russia. The industries are unchanged since 1874. The Nordeschool was founded in 1893. There are also a new archæological society and a central bureau for collecting information concerning the province. The university in 1898–99 had 397 students. Population (1874), 39,284; (1900), 66,537.

Gross-Jedlersdorf. See JEDLERSDORF.

Gross-Meseritsch, the chief town of a government district in North-east Moravia, on the Oslawa. It has considerable linen industry and leather manufactures, horse fairs, and important trade in fruit, vegetables, and flax. Population, chiefly Czech (1900), 5236.

Groton, a town of New London county, Connecticut, U.S.A., on the eastern bank of the river Thames, at its mouth. The town has an area of 35 square miles, level near the coast, but rising into hills inland. The principal village, of the same name as the town, is situated on the Thames opposite New London, and on the New York, New Haven, and Hartford Railway. Population of the town (1880), 5128; (1890), 5539; (1900), 5962, of whom 936 were foreign-born and 96 negroes.

Grottaglie, a town of the province of Lecce, Apulia, Italy, 12 miles east by north of Taranto by the railway to Brindisi. It is celebrated for a white-glaze pottery, and has also a ceramic school (1887), and olive-oil presses. Population, about 10,000.

Groups, Theory of.—The conception of an operation to be carried out on some object or set of objects underlies all mathematical science. Thus in elementary arithmetic there are the fundamental operations of the addition and the multiplication of integers; in algebra a linear transformation is an operation which may be carried out on any set of variables; while in geometry a translation, a rotation, or a projective transformation are operations which may be carried out on any figure.

In speaking of an operation, an object or a set of objects to which it may be applied is postulated; and the operation may, and generally will, have no meaning except in regard to such a set of objects. If two operations, which can be performed on the same set of objects, are such that, when carried out in succession on any possible object, the result, whichever operation is performed first, is to produce no change in the object; then each of the operations is spoken of as a *definite* operation, and each of them is called the *inverse* of the other. Thus the operations which consist in replacing x by nx and x/n respectively, in any rational function of x, are definite inverse operations, if n is any assigned number except zero. On the contrary, the operation of replacing x by an assigned number in any rational function of x is not, in the present sense, although it leads to a unique result, a definite operation; there is in fact no unique inverse operation corresponding to it. It is to be noticed that the question whether an operation is a definite operation or no may depend on the range of the objects on which it operates. For example, the operations of squaring and extracting the square root are definite inverse operations if the objects are restricted to be real positive numbers, but not otherwise.

If O, O′, O″,... is the totality of the objects on which a definite operation S and its inverse S′ may be carried out, and if the result of carrying out S on O is represented by O.S, then O.S.S′, O.S′.S, and O are the same object whatever object of the set O may be. This will be represented by the equations $SS' = S'S = 1$. Now O.S.S′ has a meaning only if O.S is an object on which S′ may be performed. Hence whatever object of the set O may be, both O.S and O.S′ belong to the set. Similarly O.S.S, O.S.S.S,... are objects of the set. These will be represented by $O.S^2$, $O.S^3$,... Suppose now that T is another definite operation with the same set of objects as S, and that T′ is its inverse operation. Then O.S.T is a definite operation of the set, and therefore the result of carrying out S and then T on the set of objects is some operation U with a unique result. Represent by U′ the result of carrying out T′ and then S′. Then

$$O.UU' = O.S.T.T'.S' = O.SS' = O,$$

and

$$O.U'U = O.T'.S'.S.T = O.T'T = O,$$

whatever object O may be. Hence

$$UU' = U'U = 1;$$

and U, U′ are definite inverse operations.

If S, U, V are definite operations, and if S′ is the inverse of S, then

$$SU = SV$$

implies $S'SU = S'SV$,

or $U = V$.

Similarly $US = VS$

implies $U = V$.

Let $S, T, U, \ldots$

be a set of definite operations, capable of being carried out on a common object or set of objects, and let the set contain— *Definition of a group.*

(i.) the operation ST, S and T being any two operations of the set;

(ii.) the inverse operation of S, S being any operation of the set;

the set of operations is then called a group.

The number of operations in a group may be either finite or infinite. When it is finite, the number is called the *order* of the group, and the group is spoken of as a *group of finite order.*

If the number of operations is infinite, there are three possible cases. When the group is represented by a set of geometrical operations, for the specification of an individual operation a number of measurements will be necessary. In more analytical language, each operation will be specified by the values of a set of parameters. If no one of these parameters is capable of continuous variation, the group is called a *discontinuous group.* If all the parameters are capable of continuous variation, the group is called a *continuous group.* If some of the parameters are capable of continuous variation and some are not, the group is called a *mixed group.*

If S′ is the inverse operation of S, a group which contains S must contain SS′, which produces no change on any possible object. This is called the *identical operation*, and will always be represented by 1. Since

$$S^pS^q = S^{p+q}$$

when p and q are positive integers, and

$$S^pS' = S^{p-1}$$

while no meaning at present has been attached to S^q when q is negative, S′ may be consistently represented by S^{-1}. Since

$$S, S^2, S^3, \ldots$$

all belong to a group which contains S, it follows that for every operation of a group of finite order there must be some smallest integer m such that

$$S^m = 1;$$

m is then called the order of the operation S, which is spoken of as an operation of finite order. Operations of finite order may, of course, occur in groups containing an infinite number of operations, but do not necessarily do so. In any case the set of operations

$$\ldots, S^{-2}, S^{-1}, 1, S, S^2, .$$

obviously constitute a group. Such a group is called a *cyclical* group, whether S is of finite order or not.

It will be convenient, before giving some illustrations of the general group idea, to add a number of further definitions and explanations which apply to all groups alike. If from among the set of operations

Subgroups, conjugate operations, isomorphism, &c

$$S, T, U, \ldots$$

which constitute a group G, a smaller set

$$S', T', U', \ldots$$

can be chosen which themselves constitute a group H, the group H is called a *subgroup* of G. Thus, in particular, if S is an operation of G, the cyclical group constituted by

$$\ldots, S^{-2}, S^{-1}, 1, S, S^2, \ldots$$

is a subgroup of G, except in the special case when it coincides with G itself.

If H is a subgroup of G, and S an operation of G, which is not contained in H, the totality of the operations formed by combining in every way S and its positive and negative powers with the operations of H necessarily forms a group. This is contained in or coincides with G. By first taking for H the cyclical subgroups of G, and continually building up in this way fresh subgroups, all possible subgroups of G will arise.

If S and T are any two operations of G, the two operations S and $T^{-1}ST$ are called *conjugate* operations, and $T^{-1}ST$ is spoken of as the result of *transforming* S by T. Since

$$(T^{-1}ST)^2 = T^{-1}ST \,.\, T^{-1}ST = T^{-1}S^2T,$$

and

$$(T^{-1}ST)^n = T^{-1}S^nT,$$

it follows that if S is an operation of finite order, $T^{-1}ST$ is an operation of the same finite order, and conversely. It is to be noted that since

$$ST = T^{-1} \,.\, TS \,.\, T,$$

ST and TS are always conjugate operations in any group containing both S and T. If T transforms S into itself, that is, if

$$S = T^{-1}ST \text{ or } TS = ST,$$

S and T are called *permutable* operations. A group whose operations are all permutable with each other is called an *Abelian* group. If S is transformed into itself by every operation of G, or, in other words, if it is permutable with every operation of G, it is called a *self-conjugate* operation of G.

The conception of operations being conjugate to each other may be extended to subgroups. If

$$S', T', U', \ldots$$

are the operations of a subgroup H, and if R is any operation of G, then the operations

$$R^{-1}S'R, R^{-1}T'R, R^{-1}U'R, \ldots$$

belong to G, and constitute a subgroup of G. For if

$$S'T' = U',$$

then

$$R^{-1}S'R \,.\, R^{-1}T'R = R^{-1}S'T'R = R^{-1}U'R.$$

This subgroup may be identical with H. In particular, it is necessarily the same as H if R belongs to H. If it is not identical with H, it is said to be *conjugate* to H; and it is in any case represented by the symbol $R^{-1}HR$. If

$$H = R^{-1}HR,$$

the operation R is said to be permutable with the subgroup H. (It is to be noticed that this does not imply that R is permutable with each operation of H.)

If

$$H = R^{-1}HR,$$

when for R is taken in turn each of the operations of G, then H is called a *self-conjugate* subgroup of G.

A group is spoken of as *simple* when it has no self-conjugate subgroup other than that constituted by the identical operation alone. A group which has a self-conjugate subgroup is called composite.

Let G be a group constituted of the operations

$$S, T, U, \ldots$$

and g a second group constituted of

$$s, t, u, \ldots$$

and suppose that to each operation of G there corresponds a single operation of g in such a way that if

$$ST = U,$$

then

$$st = u,$$

where s, t, u are the operations corresponding to S, T, U respectively. The groups are then said to be *isomorphic*, and the correspondence between their operations is spoken of as an *isomorphism* between the groups. It is clear that there may be two distinct cases of such isomorphism. To a single operation of g there may correspond either a single operation of G or more than one. In the first case the isomorphism is spoken of as *simple*, in the second as *multiple*.

Two simply isomorphic groups considered abstractly—that is to say, in regard only to the way in which their operations combine among themselves, and apart from any concrete representation of the operations—are clearly indistinguishable.

If G is multiply isomorphic with g, let

$$A, B, C, \ldots$$

be the operations of G which correspond to the identical operation of g. Then to the operations A^{-1} and AB of G there corresponds the identical operation of g; so that A, B, C,... constitute a subgroup H of G. Moreover, if R is any operation of G, the identical operation of g corresponds to every operation of $R^{-1}HR$, and therefore H is a self-conjugate subgroup of G. Since S corresponds to s, and every operation of H to the identical operation of g, therefore every operation of the set

$$SA, SB, SC, \ldots$$

which may be represented by SH, corresponds to s. Also these are the only operations that correspond to s; for if there were another such operation T, then $T^{-1}S$ would correspond to the identical operation of g, which is not the case. The operations of G may therefore be divided into sets, no two of which contain a common operation, such that the correspondence between the operations of G and g connects each of the sets

$$H, SH, TH, UH, \ldots$$

with the single operations

$$1, \quad s, \quad t, \quad u, \ldots$$

written below them. The sets into which the operations of G are thus divided combine among themselves by exactly the same laws as the operations of g. For if

$$st = u,$$

then

$$SH \,.\, TH = UH,$$

in the sense that any operation of the set SH followed by any operation of the set TH gives an operation of the set UH.

The group g, abstractly considered, is therefore completely defined by the division of the operations of G into sets in respect of the self-conjugate subgroup H. From this point of view it is spoken of as the *factor-group* of G

in respect of H, and is represented by the symbol G/H. Any composite group in a similar way defines abstractly a factor-group in respect of each of its self-conjugate subgroups.

It follows from the definition of a group that it must always be possible to choose from its operations a set such that every operation of the group can be obtained by combining the operations of the set and their inverses. If the set is such that no one of the operations belonging to it can be represented in terms of the others, it is called a set of *independent generating* operations. Such a set of generating operations may be either finite or infinite in number. If A, B,...,E are the generating operations of a group, the group generated by them is represented by the symbol $\{A, B, \ldots, E\}$. An obvious extension of this symbol is used such that $\{A, H\}$ represents the group generated by combining an operation A with every operation of a group H; $\{H_1, H_2\}$ represents the group obtained by combining in all possible ways the operations of the groups H_1 and H_2; and so on. The independent generating operations of a group may be subject to certain relations connecting them, but these must be such that it is impossible by combining them to obtain a relation expressing one operation in terms of the others. For instance,

$$AB = BA$$

is a relation conditioning the group $\{A, B\}$; it does not, however, enable A to be expressed in terms of B, so that A and B are independent generating operations

Let

$$O, O', O'', \ldots$$

be a set of objects which are interchanged among themselves by the operations of a group G, so that if S is any operation of the group, and O any one of the objects, then O . S is an object occurring in the set. If it is possible to find an operation S of the group such that O . S is any assigned one of the set of objects, the group is called *transitive* in respect of this set of objects. When this is not possible the group is called *intransitive* in respect of the set. If it is possible to find S so that any arbitrarily chosen n objects of the set, $O_1, O_2, \ldots, O_n$ are changed by S into $O'_1, O'_2, \ldots, O'_n$ respectively, the latter being also arbitrarily chosen, the group is said to be n-ply transitive.

Transitivity and primitivity.

If

$$O, O', O'', \ldots$$

is a set of objects in respect of which a group G is transitive, it may be possible to divide the set into a number of subsets, no two of which contain a common object, such that every operation of the group either interchanges the objects of a subset among themselves, or changes them all into the objects of some other subset. When this is the case the group is called *imprimitive* in respect of the set; otherwise the group is called *primitive.* A group which is doubly-transitive, in respect of a set of objects, obviously cannot be imprimitive.

If G is a group which is transitive in respect of a set of objects

$$O, O', O'', \ldots$$

no portion of the set less than the whole can be interchanged among themselves by all the operations of G. It may, however, be possible to choose a portion of the set, such that the objects it contains are interchanged among themselves by some of the operations of G. If S and T are two operations of G which have this property in respect of the portion, then ST has it also. The operations of G, which interchange among themselves the objects forming a portion of the set, constitute therefore a subgroup. In many particular cases, as will be seen in the examples presently to be dealt with, this consideration of the invariance of a portion of a transitive set of objects lends itself readily to the determination of the subgroups of the group under examination.

The foregoing general definitions and explanations will now be illustrated by a consideration of certain particular groups. To begin with, as the operations involved are of the most familiar nature, the group of rational arithmetic may be considered. The fundamental operations of elementary arithmetic consist in the addition and subtraction of integers, and multiplication and division by integers, division by zero alone omitted. Multiplication by zero is not a definite operation, and it must therefore be omitted in dealing with those operations of elementary arithmetic which form a group. The operation that results from carrying out additions, subtractions, multiplications, and divisions, of and by integers a finite number of times, is represented by the relation

Illustrations of the group idea.

$$x = ax + b,$$

where a and b are rational numbers of which a is not zero, x is the object of the operation, and x' is the result. The totality of operations of this form obviously constitutes a group; for if

$$x'' = a_1x' + b_1$$

is a second operation of the same kind, the operation that results from carrying out the first and then the second is

$$x'' = aa_1x + a_1b + b_1,$$

which belongs to the set. Moreover, the inverse of the first operation is

$$x' = \frac{1}{a}x - \frac{b}{a},$$

which also belongs to the set.

If S and T represent respectively the operations

$$x' = ax + b$$

and

$$x' = cx + d,$$

then $T^{-1}ST$ represents

$$x' = ax + d - ad + bc.$$

When a and b are given rational numbers, c and d may be chosen in an infinite number of ways as rational numbers, so that $d - ad + bc$ shall be any assigned rational number. Hence the operations given by

$$x' = ax + b,$$

where a is an assigned rational number and b is any rational number, are all conjugate; and no two such operations for which the a's are different can be conjugate. If a is unity and b zero, S is the identical operation which is necessarily self-conjugate. If a is unity and b different from zero, the operation

$$x' = x + b$$

is an addition. The totality of additions forms, therefore, a single conjugate set of operations. Moreover, the totality of additions with the identical operation, *i.e.*, the totality of operations of the form

$$x' = x + b,$$

where b may be any rational number or zero, obviously constitutes a group. The operations of this group are interchanged among themselves when transformed by any operation of the original group. It is therefore a self-conjugate subgroup of the original group.

The totality of multiplications, with the identical operation, *i.e.*, all operations of the form

$$x' = ax,$$

where a is any rational number other than zero, again obviously constitutes a group. This, however, is not a

self-conjugate subgroup of the original group. In fact, if the operations

$$x' = ax$$

are all transformed by

$$x' = cx + d,$$

they give rise to the set

$$x' = ax + d(1 - a).$$

When d is a given rational number, the set constitutes a subgroup which is conjugate to the group of multiplications. It is to be noticed that the operations of this latter subgroup may be written in the form

$$x' - d = a(x - d).$$

A complete discussion of all the subgroups of the group under consideration is not here called for, as the present object is merely to illustrate the definitions and general properties that apply to all groups alike; but further subgroups will immediately suggest themselves to the reader. For instances, all operations of the form

$$x' = a^n x + b,$$

where a is a given rational number, n a positive or negative integer, and b any rational number, obviously constitute a subgroup which is self-conjugate.

The totality of rational numbers, including zero, forms a set of objects which are interchanged among themselves by all operations of the group.

If x_1 and x_2 are any pair of distinct rational numbers, and y_1 and y_2 any other pair, there is just one operation of the group which changes x_1 and x_2 into y_1 and y_2 respectively. For the equations

$$y_1 = ax_1 + b,$$
$$y_2 = ax_2 + b,$$

determine a and b uniquely. The group is therefore doubly transitive in respect of the set of rational numbers. If H is the subgroup that leaves unchanged a given rational number x_1, and S an operation changing x_1 into x_2, then every operation of $S^{-1}HS$ leaves x_2 unchanged. The subgroups, each of which leaves a single rational number unchanged, therefore form a single conjugate set. The group of multiplications leaves zero unchanged; and, as has been seen, this is conjugate with the subgroup formed of all operations

$$x' - d = a(x - d),$$

where d is a given rational number. This subgroup leaves d unchanged.

The group of multiplications is clearly generated by the operations

$$x' = px,$$

where for p negative unity and each prime is taken in turn. Every addition is obtained on transforming

$$x' = x + 1$$

by the different operations of the group of multiplications. Hence

$$x' = x + 1, \text{ and } x' = px, \ (p = -1, 3, 5, 7, \ldots)$$

form a set of independent generating operations of the group. It is a discontinuous group.

As a second example the group of motions in three-dimensional space will be considered. The totality of motions, *i.e.*, of space displacements which leave the distance of every pair of points unaltered, obviously constitutes a set of operations which satisfies the group definition. From the elements of kinematics it is known that every motion is either (i.) a translation which leaves no point unaltered, but changes each of a set of parallel lines into itself; or (ii.) a rotation which leaves every point of one line unaltered and changes every other point and line; or (iii.) a twist which leaves no point and only one line (its axis) unaltered, and may be regarded as a translation along, combined with a rotation round, the axis. Let S be any motion consisting of a translation l along and a rotation α round a line AB, and let T be any other motion. There is some line CD into which T changes AB; and therefore $T^{-1}ST$ leaves CD unchanged. Moreover, $T^{-1}ST$ clearly effects the same translation along and rotation round CD that S effects for AB. Two motions, therefore, are conjugate if and only if the amplitudes of their translation and rotation components are respectively equal. In particular, all translations of equal amplitude are conjugate, as also are all rotations of equal amplitude. Any two translations are permutable with each other, and give when combined another translation. The totality of translations constitutes, therefore, a subgroup of the general group of motions; and this subgroup is a self-conjugate subgroup, since a translation is always conjugate to a translation.

All the points of space constitute a set of objects which are interchanged among themselves by all operations of the group of motions. So also do all the lines of space and all the planes. In respect of each of these sets the group is simply transitive. In fact, there is an infinite number of motions which change a point A to A′, but no motion can change A and B to A′ and B′ respectively unless the distance AB is equal to the distance A′B′.

The totality of motions which leave a point A unchanged forms a subgroup. It is clearly constituted of all possible rotations about all possible axes through A, and is known as the group of rotations about a point. Every motion can be represented as a rotation about some axis through A followed by a translation. Hence if G is the group of motions and H the group of translations, G/H is simply isomorphic with the group of rotations about a point

The group of rotations round a point is an example of a simple group. To verify this, suppose that a self-conjugate subgroup of the group of rotations round A contains a rotation through an angle α about $A\alpha$. Since the group of rotations round A has operations which change any one line through A into any other, the self-conjugate subgroup contains rotations of amplitude α round every line through A. Now a pair of lines AB, AC can always be chosen so that a rotation of amplitude α round AB followed by one of amplitude $-\alpha$ round AC is equivalent to a rotation of arbitrarily chosen amplitude round some other line AD. The self-conjugate subgroup then contains rotations of all possible amplitudes about all possible lines through A. In other words, it coincides with the group of rotations about A.

The totality of the motions which leave a given line unchanged forms a subgroup. It is constituted of all the twists which have the given line for axis, and of rotations through two right angles about all lines which meet the given line at right angles.

Similarly, the totality of motions which leave a given plane unaltered forms a subgroup. It is constituted of all translations parallel to the plane, all rotations about lines perpendicular to the plane, and rotations through two right angles about all lines in the plane.

The totality of the motions which bring a given solid to congruence with itself again constitutes a subgroup of the group of motions. This will in general be the trivial subgroup formed of the identical operation above, but may in the case of a symmetrical body be more extensive. For a sphere or a right circular cylinder the subgroups are those that leave the centre and the axis respectively unaltered. For a solid bounded by plane faces the subgroup is clearly one of finite order. In particular, to each of the regular solids there corresponds such a group. That for the tetrahedron has 12 for its order; for the

cube (or octahedron) 24, and for the icosahedron (or dodecahedron) 60.

The determination of a particular operation of the group of motions involves six distinct measurements; namely, four to give the axis of the twist, one for the magnitude of the translation along the axis, and one for the magnitude of the rotation about it. Each of the six quantities involved may have any value whatever, and the group of motions is therefore a continuous group. On the other hand, a subgroup of the group of motions which leaves a line or a plane unaltered is a mixed group.

Continuous Groups.

We shall discuss separately continuous groups, discontinuous groups, and groups of finite order; and, as they are in a sense the most general, we shall begin with the theory of continuous groups.

The determination of a particular operation of a given continuous group depends on assigning special values to each one of a set of parameters which are capable of continuous variation. The first distinction regards the number of these parameters. If this number is finite, the group is called a *finite* continuous group; if infinite, it is called an *infinite* continuous group. In the latter case arbitrary functions must appear in the equations defining the operations of the group when these are reduced to an analytical form. The theory of infinite continuous groups has not hitherto received the same amount of attention, nor is it yet so completely developed as that of finite continuous groups. The latter theory will mainly occupy us here, and the former will not be entered upon in any detail.

Sophus Lie, to whom the foundation and a great part of the development of the theory of continuous groups are due, undoubtedly approached the subject from a geometrical standpoint. His conception of an operation is to regard it as a geometrical transformation, by means of which each point of (n-dimensional) space is changed into some other definite point.

The representation of such a transformation in analytical form involves a system of equations,

$$x'_s = f_s(x_1, x_2, \ldots, x_n), \quad (s = 1, 2, \ldots, n),$$

expressing $x_1', x_2', \ldots, x'_n$, the co-ordinates of the transformed point in terms of $x_1, x_2, \ldots, x_n$, the co-ordinates of the original point. In these equations the functions f_s are analytical functions of their arguments. Within a properly limited region they must be one-valued, and the equations must admit a unique solution with respect to $x_1, x_2, \ldots, x_n$; since the operation would not otherwise be a definite one.

From this point of view the operations of a continuous group, which depends on a set of r parameters, will be defined analytically by a system of equations of the form

$$x'_s = f_s(x_1, x_2, \ldots, x_n;\ a_1, a_2, \ldots, a_r), \quad (s = 1, 2, \ldots, n), \tag{i.}$$

where $a_1, a_2, \ldots, a_r$ represent the parameters. If this operation be represented by A, and that in which $b_1, b_2, \ldots, b_r$ are the parameters by B, then the operation AB is represented by the elimination (assumed to be possible) of $x'_1, x'_2, \ldots, x'_n$ between the equations

$$x'_s = f_s(x_1, x_2, \ldots, x_n;\ a_1, a_2, \ldots, a_r), \quad (s = 1, 2, \ldots, n),$$

and

$$x''_s = f_s(x'_1, x'_2, \ldots, x'_n;\ b_1, b_2, \ldots, b). \quad (s = 1, 2, \ldots, n).$$

Since AB belongs to the group, the result of the elimination must be

$$x''_s = f_s(x_1, x_2, \ldots, x_n;\ c_1, c_2, \ldots, c_r),$$

where $c_1, c_2, \ldots, c_r$ represent another definite set of values of the parameters. Moreover, since A^{-1} belongs to the group, the result of solving equations (i.) with respect to $x_1, x_2 \ldots, x_n$ must be

$$x_s = f_s(x'_1, x'_2, \ldots, x'_n;\ d_1, d_2, \ldots, d_r), \quad (s = 1, 2, \ldots, n).$$

Conversely, if equations (i.) are such that these two conditions are satisfied, they do in fact define a finite continuous group.

It will be assumed that the r parameters which enter in equations (i.) are independent, *i.e.*, that it is impossible to choose r' $(<r)$ quantities in terms of which $a_1, a_2, \ldots, a_r$ can be expressed. Where this is the case the group will be spoken of as a "group of order r." Lie uses the term "*r-gleidrige Gruppe.*" It is to be noticed that the word order is used in quite a different sense from that given to it in connexion with groups of finite order.

As examples of systems of equations thus defining continuous groups, the following simple instances may be considered. First

$$x' = a_1 x + a_2,$$

where a_1 and a_2 are continuously varying parameters, subject to the condition

$$a_1 \neq 0.$$

This equation agrees in form with that already considered in connexion with the arithmetical group, and does not require further comment. Its geometrical signification as defining a projective transformation of a straight line, which leaves the point at infinity unaltered, will be obvious to the reader. Secondly,

$$x' = x\cos a_1 - y\sin a_1 + a_2,$$
$$y' = x\sin a_1 + y\cos a_1 + a_3,$$

where a_1, a_2, a_3 are the parameters.

That these equations actually satisfy the conditions may be easily verified directly. Their geometrical meaning, as representing in analytical form the most general "motion" in a plane, is again obvious. Thirdly,

$$x' = \frac{a^2x - a(x^2+y^2)}{(x-a)^2+y^2},$$
$$y' = \frac{a^2y}{(x-a)^2+y^2},$$

where a is the single parameter. It will be found that the result of combining two pairs of equations of this form, in which the parameters are a and b, leads to a new pair of equations of the same form in which the parameter is $ab/(a+b)$. Also that the result of solving the two given equations with respect to x and y leads again to a pair of equations of the same form with $-a$ for parameter. The equations therefore define a continuous group with a single parameter.

Infinitesimal operations of a continuous group.

Returning now to equations (i.), which define the general operation of the group, it is to be noticed that, since the group contains the identical operation, these equations must for some definite set of values of the parameters reduce to

$$x'_1 = x_1,\ x'_2 = x_2, \ldots, x'_n = x_n.$$

This set of values may, without loss of generality, be assumed to be simultaneous zero values. For if $i_1, i_2, \ldots, i_r$ be the values of the parameters which give the identical operation, and if we write

$$a_s = i_s + \alpha_s, \quad (s = 1, 2, \ldots, r),$$

then zero values of the new parameters $\alpha_1, \alpha_2, \ldots, \alpha_r$ give the identical operation.

To infinitesimal values of the parameters, thus chosen, will correspond operations which cause an infinitesimal change in each of the variables. These are called

infinitesimal operations. The most general infinitesimal operation of the group is that given by the system

$$x'_s - x_s = \delta x_s = \frac{\partial f_s}{\partial a_1}\cdot\delta a_1 + \frac{\partial f_s}{\partial a_2}\cdot\delta a_2 + \ldots + \frac{\partial f_s}{\partial a_r}\cdot\delta a_r,$$
$$(s = 1,\ 2,\ldots,\ n),$$

where, in $\frac{\partial f_s}{\partial a_i}$, zero values of the parameters are to be taken. Since a_1, $a_2,\ldots,a_r$ are independent, the ratios of δa_1, δa_2, ..., δa_r are arbitrary. Hence the most general infinitesimal operation of the group may be written in the form

$$\delta x_s = \left(e_1\frac{\partial f_s}{\partial a_1} + e_2\frac{\partial f_s}{\partial a_2} + \ldots + e_r\frac{\partial f_s}{\partial a_r}\right)\delta t,$$
$$(s = 1,\ 2,\ldots,\ n),$$

where e_1, $e_2,\ldots,e_r$ are arbitrary constants, and δt is an infinitesimal.

If $F(x_1, x_2,\ldots,x_n)$ is any function of the variables, and if an infinitesimal operation of the group be carried out on the variables in F, the resulting increment of F will be

$$\frac{\partial F}{\partial x_1}\cdot\delta x_1 + \frac{\partial F}{\partial x_2}\cdot\delta x_2 + \ldots + \frac{\partial F}{\partial x_n}\cdot\delta x_n.$$

When in this expression their values are written for δx_1, $\delta x_2,\ldots$, it becomes

$$\begin{aligned}
&e_1\left(\frac{\partial f_1}{\partial a_1}\frac{\partial F}{\partial x_1} + \frac{\partial f_2}{\partial a_1}\frac{\partial F}{\partial x_2} + \ldots + \frac{\partial f_n}{\partial a_1}\frac{\partial F}{\partial x_n}\right)\delta t\\
+\,&e_2\left(\frac{\partial f_1}{\partial a_2}\frac{\partial F}{\partial x_1} + \frac{\partial f_2}{\partial a_2}\frac{\partial F}{\partial x_2} + \ldots + \frac{\partial f_n}{\partial a_2}\frac{\partial F}{\partial x_n}\right)\delta t\\
+\,&\quad\cdot\qquad\cdot\qquad\cdot\qquad\cdot\qquad\cdot\\
+\,&\quad\cdot\qquad\cdot\qquad\cdot\qquad\cdot\qquad\cdot\\
+\,&e_r\left(\frac{\partial f_1}{\partial a_r}\frac{\partial F}{\partial x_1} + \frac{\partial f_2}{\partial a_r}\frac{\partial F}{\partial x_2} + \ldots + \frac{\partial f_n}{\partial a_r}\frac{\partial F}{\partial x_n}\right)\delta t.
\end{aligned}$$

If now the differential operator

$$\frac{\partial f_1}{\partial a_i}\frac{\partial}{\partial x_1} + \frac{\partial f_2}{\partial a_i}\frac{\partial}{\partial x_2} + \ldots + \frac{\partial f_n}{\partial a_i}\frac{\partial}{\partial x_n}$$

be represented by

$$X_i,$$
$$(i = 1,\ 2,\ldots,\ r),$$

then the increment of F when an infinitesimal operation of the group is carried out on the variables is given by

$$(e_1X_1 + e_2X_2 + \ldots + e_rX_r)F\ \ \delta t.$$

When the equations (i.) defining the general operation of the group are given, the co-efficients $\frac{\partial f_s}{\partial a_i}$ which enter in these differential operators are functions of the variables which can be directly calculated.

The differential operator

$$e_1X_1 + e_2X_2 + \ldots + e_rX_r$$

may be regarded as defining the most general infinitesimal operation of the group. In fact, if it be for a moment represented by X, then $(1 + \delta t X)F$ is the result of carrying out the infinitesimal operation on F; and by putting $x_1, x_2,\ldots,x_n$ in turn for F, the actual infinitesimal operation is reproduced. By a very convenient, though perhaps hardly justifiable, phraseology, this differential operator is itself spoken of as the general infinitesimal operation of the group. The sense in which this phraseology is to be understood will be made clear by the foregoing explanations.

We suppose now that the constants e_1, $e_2,\ldots,e_r$ have assigned values. Then the result of repeating the particular infinitesimal operation

$$e_1X_1 + e_2X_2 + \ldots + e_rX_r$$

or X, an infinite number of times is some finite operation of the group. The effect of this finite operation on F may be directly calculated. In fact, if δt is the infinitesimal already introduced, then

$$\frac{dF}{dt} = X.F,\ \frac{d^2F}{dt^2} = X.X.F,\ldots$$

Hence

$$\begin{aligned}F' &= F + t\frac{dF}{dt} + \frac{t^2}{1.2}\frac{d^2F}{dt^2} + \ldots\\ &= F + tX.F + \frac{t^2}{1.2}X.X.F + \ldots\end{aligned}$$

It must, of course, be understood that in this analytical representation of the effect of the finite operation on F, it is implied that t is taken sufficiently small to ensure the convergence of the (in general) infinite series.

When x_1, $x_2,\ldots$ are written in turn for F, the system of equations

$$x'_s = (1 + tX + \frac{t^2}{1.2}X.X + \ldots)x_s \qquad \text{(ii.)}$$
$$(s = 1,\ 2,\ ..,\ n)$$

represent the finite operation completely. If t is here regarded as a parameter, this set of operations must in themselves constitute a group, since they arise by the repetition of a single infinitesimal operation. That this is really the case results immediately from noticing that the result of eliminating F′ between

$$F' = F + tX.F + \frac{t^2}{1.2}X.X.F + \ldots$$

and

$$F'' = F' + t'X.F' + \frac{t'^2}{1.2}X.X.F' + \ldots$$

is

$$F'' = F + (t + t')X.F + \frac{(t + t')^2}{1.2}X.X.F + \ldots$$

The group thus generated by the repetition of an infinitesimal operation is called a *cyclical* group; so that a continuous group contains a cyclical subgroup corresponding to each of its infinitesimal operations.

The system of equations (ii.) represents an operation of the group whatever the constants e_1, $e_2,\ldots,e_r$ may be. Hence if e_1t, $e_2t,\ldots$, e_rt be replaced by a_1, $a_2,\ldots$, a_r the equations (ii.) represent a set of operations, depending on r parameters and belonging to the group. They must, therefore, be a form of the general equations for any operation of the group, and are therefore equivalent to the equations (i.). The determination of the finite equations of a cyclical group, when the infinitesimal operation which generates it is given, will always depend on the integration of a set of simultaneous ordinary differential equations. As a very simple example we may consider the case in which the infinitesimal operation is given by

$$X = x^2\frac{\partial}{\partial x},$$

so that there is only a single variable. The relation between x' and t is given by

$$\frac{dx'}{dt} = x'^2,$$

with the condition that $x' = x$, when $t = 0$. This gives at once

$$x' = \frac{x}{1 - tx},$$

which might also be obtained by the direct use of (ii.).

Relations between the infinitesimal operations of a finite continuous group.

When the finite equations (i.) of a continuous group of order r are known, it has now been seen that the differential operator which defines the most general infinitesimal operation of the group can be directly constructed, and that it contains r arbitrary constants. This is equivalent to saying that the group contains r linearly independent infinitesimal operations; and that the most general infinitesimal operation is obtained by combining these linearly with constant coefficients. Moreover, when any r independent infinitesimal operations of the group are known, it has been seen how the general finite operation of the group may be calculated. This obviously suggests that it must

be possible to define the group by means of its infinitesimal operations alone; and it is clear that such a definition would lend itself more readily to some applications (for instance, to the theory of differential equations) than the definition by means of the finite equations.

On the other hand, r arbitrarily given linear differential operators will not, in general, give rise to a finite continuous group of order r; and the question arises as to what conditions such a set of operators must satisfy in order that they may, in fact, be the independent infinitesimal operations of such a group. A system of necessary relations between the infinitesimal operations may be directly deduced from the point of view already taken. Let X and Y be two infinitesimal operations of a finite group, and let X_t, $Y_{t'}$, be finite operations which result from repeating X and Y an infinite number of times. Then it has already been seen that

$$1 + tX + \frac{t^2}{1.2}X.X + \dots$$

and

$$1 + t'Y + \frac{t'^2}{1.2}Y.Y + \dots$$

are the differential operators which give the effect of X_t and $Y_{t'}$ on any function of the variables. The differential operator for $X_tY_{t'}X_{-t}Y_{-t'}$ will now be calculated. That for $X_tY_{t'}$ is

$$\left(1 + t'Y + \frac{t'^2}{1.2}Y.Y + \dots\right)\left(1 + tX + \frac{t^2}{1.2}X.X + \dots\right)$$
$$= 1 + tX + t'Y + \frac{t^2}{1.2}X.X + tt'Y.X + \frac{t'^2}{1.2}Y.Y + \dots$$

where the unwritten terms are of the 3rd order in t and t' combined. Similarly that for $X_{-t}Y_{-t'}$ is

$$1 - tX - t'Y + \frac{t^2}{1.2}X.X + tt'Y.X + \frac{t'^2}{1.2}Y.Y + \dots$$

Hence the differential operator which gives the effect of $X_tY_{t'}X_{-t}Y_{-t'}$ is $1 - tt'(X.Y - Y.X) +$ terms of the 3rd order in t and t'. If t and t' are here regarded as infinitesimals of the order $\frac{1}{2}$, the unwritten terms vanish in comparison with that written, and therefore

$$1 - \delta t(X.Y - Y.X)$$

must give the effect of an infinitesimal operation of the group on any function of the variables. In other words,

$$X.Y - Y.X$$

is an infinitesimal operation of the group. That $X.Y - Y.X$ is a linear differential operator is evident when for X and Y their actual values are written. This operator is represented by (XY), and is called the *combinant* of X and Y. Lie uses the expression *Klammerausdruck*. The result thus arrived at may be expressed in words by saying that among the infinitesimal operations of any finite continuous group must be included the combinant of every pair of infinitesimal operations.

Let

$$X_1, X_2, \dots, X_r$$

be a set of independent infinitesimal operations of a continuous group of order r, so that every infinitesimal operation can be represented by combining them linearly with constant coefficients. Then the above conditions will be expressed by the system of equations

$$(X_iX_j) = \sum_{s=1}^{s=r} c_{ijs}X_s, \qquad \text{(iii.)}$$
$$(i, j = 1, 2, \dots, r).$$

In these equations c_{ijs} are constants, among which certain relations hold. In fact, if X_i, X_j, X_k are any three linear operators, the identity (known as Jacobi's)

$$(X_i(X_jX_k)) + (X_j(X_kX_i)) + (X_k(X_iX_j)) = 0$$

holds among them; while from the definition of the combinant

$$(X_iX_j) + (X_jX_i) = 0.$$

When the values of the combinants are substituted from (iii.) in these relations, it is found that the c's are subject to the relations

$$\left.\begin{array}{l} c_{ijt} + c_{jit} = 0 \\ \text{and} \\ \sum_s (c_{jks}c_{ist} + c_{kis}c_{jst} + c_{ijs}c_{kst}) = 0 \end{array}\right\} \qquad \text{(iv.)}$$

for all values of i, j, k, and t.

The fundamental theorem of the theory of finite continuous groups is now that these conditions, which have been shown to be necessary in order that $X_1, X_2, \dots, X_r$ may generate, as infinitesimal operations, a continuous group of order r, are also sufficient.

For the general proof of this fundamental theorem the reader must be referred to Lie's works (cf. Lie-Engel, i. chap. 9; iii. chap. 25: see Bibliography at the end of this article), as it would take up more room than can be spared in this necessarily brief account of group-theory. The general lines on which the proof runs, and the essential geometrical ideas which underlie it, can, however, be made clear to the reader by considering the particular case $n = 1$ and $r = 2$.

Let

$$X_1 = f_1(x)\frac{d}{dx}$$

and

$$X_2 = f_2(x)\frac{d}{dx}$$

be two infinitesimal operations in a single variable. Then if

$$X = a_1X_1 + a_2X_2,$$
$$x' = (1 + X + \frac{1}{1.2}X.X + \dots)x$$

is a set of transformations with two parameters, or a set of ∞^2 transformations of the variable x. This set contains the identical transformation corresponding to $a_1 = a_2 = 0$.

If T and T′ are any two transformations of the set, then the condition that the set shall constitute a group is that TT′ shall belong to the set. Now when TT′ is actually formed it will in general depend on more than two parameters. If, however, the set TT′ depends only on two independent parameters, it must coincide with the set T, since for T′ the identical transformation may be chosen. Hence the sufficient condition that the set of transformations

$$x' = (1 + X + \frac{1}{1.2}X.X + \dots)x \dots (a)$$

should be a group is that the operation, which results from carrying out in succession any two operations of the set, should contain only two independent parameters.

The set of transformations (a) may be regarded geometrically as effecting a transformation of the points of a straight line. An arbitrarily chosen point of the line will be changed successively by the operations of the set into ∞^1 new positions. A pair of arbitrarily chosen points must, however, be changed into ∞^2 new positions by the operations of the set. For if every operation of the set which brings A to a definite new position A′ at the same time brings a second arbitrarily chosen point B to a definite new position B′, the totality of points on the line only takes up ∞^1 new positions, and the set could only contain ∞^1 distinct transformations. *À fortiori* three or more arbitrarily chosen points on the line are changed into ∞^2 new positions by the set of transformations.

Let now x, y, z be the symbols defining a set of three arbitrarily chosen points on the line. These three symbols may also be regarded as the co-ordinates of a point P in three-dimensional space. Hence under the set of transforma-

tions the point P takes up ∞^2 new positions in space; in other words, P is displaced on a certain surface. This surface may either be changed into itself by every transformation of the set TT′, or it may be changed into ∞^1 or into ∞^2 new surfaces. In the two latter cases the point P will be changed into ∞^3 new positions by the transformations of the set TT′. Hence the set of transformations TT′ will contain just two independent parameters if, and only if, each of a singly-infinite set of surfaces is changed into itself by every operation of the set T. Now the infinitesimal operations of the set, when regarded as affecting the set of three symbols x, y, z, are

$$f_1(x)\frac{\partial}{\partial x}+f_1(y)\frac{\partial}{\partial y}+f_1(z)\frac{\partial}{\partial z},$$

or

$$X_1+Y_1+Z_1, \text{ or } U_1;$$

and

$$f_2(x)\frac{\partial}{\partial x}+f_2(y)\frac{\partial}{\partial y}+f_2(z)\frac{\partial}{\partial z},$$

or

$$X_2+Y_2+Z_2, \text{ or } U_2.$$

Let

$$F(x, y, z)-C=0,$$

where C is an arbitrary constant, be the set of surfaces, each of which is changed into itself by every operation of the set, then F must be a common solution of the two linear partial differential equations

$$U_1F=0,\ U_2F=0.$$

Conversely, by tracing the argument backwards, it follows that if these differential equations have a common solution, then the set of operations forms a group.

Now the well-known condition that these equations should have a common solution is that functions α, β, of x, y, z should exist such that

$$(U_1U_2)=\alpha U_1+\beta U_2.$$

But, by direct calculation

$$(U_1U_2)=(X_1X_2)+(Y_1Y_2)+(Z_1Z_2),$$

where (X_1X_2), (Y_1Y_2), (Z_1Z_2) contain respectively only differentiations with respect to x, y, and z.

Hence

$$(X_1X_2)=\alpha X_1+\beta X_2,$$
$$(Y_1Y_2)=\alpha Y_1+\beta Y_2,$$
$$(Z_1Z_2)=\alpha Z_1+\beta Z_2.$$

From the first of these equations it follows that α and β do not depend on y or z, and from the second that they do not depend on z or x. Hence they are constants. Finally, then, the sufficient condition that X_1 and X_2 should generate a continuous group of order two is that it may be possible to find constants α and β, such that

$$(X_1X_2)=\alpha X_1+\beta X_2.$$

In the more elaborate proof of the general theorem, a set of $(r+1)$ points in space of n dimensions and a single point in space of $(r+1)n$ dimensions replace the set of three points on a line and the one point in three-dimensional space here considered.

Determination of the distinct types of continuous groups of a given order.

If two continuous groups of order r are such that, for each, a set of linearly independent infinitesimal operations

$$X_1, X_2, \dots, X_r,$$

and

$$Y_1, Y_2, \dots, Y_r,$$

can be chosen, so that in the relations

$$(X_iX_j)=\Sigma c_{ijs}X_s, \qquad \text{(iii.)}$$

and

$$(Y_iY_j)=\Sigma d_{ijs}Y_s,$$

the constants c_{ijs} and d_{ijs} are the same for all values of i, j, and s, the two groups are simply isomorphic, X_s and Y_s being corresponding infinitesimal operations. This follows from noticing that the two groups have necessarily corresponding systems of subgroups. In fact, the problem of determining all the subgroups of the continuous group generated by

$$X_1, X_2, \dots, X_r$$

is clearly the same as that of finding all systems of s $(<r)$ infinitesimal operations

$$X'_1=a_{11}X_1+a_{12}X_2+\dots+a_{1r}X_r,$$
$$X'_2=a_{21}X_1+a_{22}X_2+\dots+a_{2r}X_r,$$
$$\cdot\quad\cdot\quad\cdot\quad\cdot$$
$$X'_s=a_{s1}X_1+a_{s2}X_2+\dots+a_{sr}X_r,$$

such that each combinant $(X'_iX'_j)$, $(i, j=1, 2\dots, s)$ can be expressed linearly in terms of $X'_1, X'_2\dots, X'_s$. Corresponding to each solution of this problem for the X's there is clearly one with the same set of constants for the Y's.

Two continuous groups of order r, whose infinitesimal operations obey the same system of equations (iii.), may be of very different *form*; for instance, the number of variables for the one may be different from that for the other. They are, however, said to be of the same *type*, in the sense that the laws according to which their operations combine are the same for both.

The problem of determining all distinct types of groups of order r is then contained in the purely algebraical problem of finding all the systems of r^3 quantities c_{ijs} which satisfy the relations

$$c_{ijt}+c_{jit}=0,$$
$$\sum_s(c_{ijs}c_{skt}+c_{jks}c_{sit}+c_{kis}c_{sjt})=0,$$

for all values of i, j, k, and t. To two distinct solutions of the algebraical problem, however, two distinct types of group will not necessarily correspond. In fact,

$$X_1, X_2, \dots, X_r$$

may be replaced by any r independent linear functions of themselves, and the c's will then be transformed by a linear substitution containing r^2 independent parameters. This, however, does not alter the type of group considered

For a single parameter there is, of course, only one type of group, which has been called cyclical.

For a group of order two there is a single relation

$$(X_1X_2)=\alpha X_1+\beta X_2.$$

If α and β are not both zero, let α be finite. The relation may then be written

$$(\alpha X_1+\beta X_2, \tfrac{1}{\alpha}X_2)=\alpha X_1+\beta X_2.$$

Hence if

$$\alpha X_1+\beta X_2=X'_1,$$
$$\tfrac{1}{\alpha}X_2=X'_2,$$

then

$$(X'_1X'_2)=X'_1.$$

There are, therefore, just two types of group of order two, the one given by the relation last written, and the other by

$$(X_1X_2)=0.$$

Lie has determined all distinct types of continuous groups of orders three or four; and all types of non-integrable groups (a term which will be explained immediately) of orders five and six (cf. Lie-Engel, iii. pp. 713–744).

A problem of fundamental importance in connexion

with any given continuous group is the determination of the self-conjugate subgroups which it contains. Closely related to this is the determination of all distinct types of simple groups. We shall proceed to deal shortly with the first of these two questions, and to state the results which have been arrived at with respect to the second.

Self-conjugate subgroups. Simple groups.

If A is a given operation of the group, and B any other operation, the operations $B^{-1}AB$ have been defined as those which are conjugate to A. The actual form of the infinitesimal operations which are conjugate to a given one may be determined thus.

Let X be the differential operator defining an infinitesimal operation A, and let Y be any infinitesimal operation. If B is the result of repeating Y an infinite number of times, the differential operator which gives the effect of $B^{-1}AB$ on any function of the variables is

$$(1 - t'Y + \frac{t'^2}{1.2}Y^2\ldots)\ (1 + \delta tX)\ (1 + t'Y + \frac{t'^2}{1.2}Y^2 + \ldots).$$

On actual calculation this is found to be

$$1 + \delta t[X + t'(XY) + \frac{t'^2}{1.2}((XY)Y) + \frac{t'^3}{1.2.3}(((XY)Y)Y) + \ldots],$$

and therefore the general form of the set of infinitesimal operations which are conjugate to X is

$$X + t'(XY) + \frac{t'^2}{1.2}((XY)Y) + \frac{t'^3}{1.2.3}(((XY)Y)Y) + \ldots$$

Hence $(XY) = 0$ is the sufficient condition that B may be permutable with A; and when this condition is satisfied every operation of the cyclical group generated by Y is permutable with every operation of that generated by X. Now a self-conjugate subgroup which contains X must contain all the operations conjugate to X, and therefore it must contain (XY), where Y is any infinitesimal operation of the group. Hence if $X'_1, X'_2, \ldots, X'_s$ are s linearly independent operations of the group which generate a self-conjugate subgroup of order s, then for *every* infinitesimal operation Y of the group relations of the form

$$(X'_iY) = \sum_{e=1}^{e=s} a_{ie}X'_e$$
$$(i = 1,\ 2, \ldots, s)$$

must be satisfied. Conversely, if such a set of relations is satisfied, $X'_1, X'_2, \ldots, X'_s$ generate a subgroup of order s, which contains every operation conjugate to each of the infinitesimal generating operations, and is therefore a self-conjugate subgroup. A specially important self-conjugate subgroup is that generated by the combinants of the r infinitesimal generating operations. That these generate a self-conjugate subgroup follows from the relations (iii.). In fact,

$$((X_iX_j)X_k) = \sum_s c_{ijs}\ (X_sX_k).$$

Of the $\frac{1}{2}r(r-1)$ combinants not more than r can be linearly independent. When exactly r of them are linearly independent, the self-conjugate group generated by them coincides with the original group. If the number that are linearly independent is less than r, the self-conjugate subgroup generated by them is actually a subgroup; *i.e.*, its order is less than that of the original group. This subgroup is known as the derived group, and Lie has called a group *perfect* when it coincides with its derived group. A simple group, since it contains no self-conjugate subgroup distinct from itself, is necessarily a perfect group.

If G is a given continuous group, G_1 the derived group of G, G_2 that of G_1, and so on, the series of groups

$$G,\ G_1,\ G_2, \ldots$$

will terminate either with the identical operation or with a perfect group; for the order of G_{s+1} is less than that of G_s unless G_s is a perfect group. When the series terminates with the identical operation, G is said to be an *integrable* group; in the contrary case G is called *non-integrable.*

If G is an integrable group of order r, the infinitesimal operations

$$X_1,\ X_2, \ldots,\ X_r$$

which generate the group may be chosen so that

$$X_1,\ X_2, \ldots,\ X_{r_1},\ (r_1 < r)$$

generate the first derived group,

$$X_1,\ X_2, \ldots,\ X_{r_2},\ (r_2 < r_1)$$

the second derived group, and so on. When they are so chosen the constants c_{ijs} are clearly such that if

$$r_p < i \leqq r_{p+1},\ r_q < j \leqq r_{q+1},\ p \geqq q,$$

then c_{ijs} vanishes unless

$$s \leqq r_{p+1}.$$

In particular the generating operations may be chosen so that c_{ijs} vanishes unless s is equal to or less than the smaller of the two numbers i, j; and conversely, if the c's satisfy these relations, the group is integrable.

The derived group is not the only self-conjugate subgroup of a given continuous group whose definition is independent of the particular type.

If

$$a_k = \sum_s c_{kss}$$

the infinitesimal operations

$$e_1X_1 + e_2X_2 + \ldots + e_rX_r,$$

where

$$a_1e_1 + a_2e_2 + \ldots + a_re_r = 0$$

generate a self-conjugate subgroup (Lie-Engel, iii. p. 692). If the a's are not all identically zero, the set of infinitesimal operations contains $r-1$ that are linearly independent, and therefore $r-1$ is the order of the subgroup. If, however, the a's all vanish, there is no relation among the e's, and the subgroup coincides with the original group.

In illustration of the present section, non-integrable groups of order three may be considered. It has been seen that all groups of order two are integrable, and therefore a group of order three must be either integrable or simple. If X_1, X_2, X_3 are the infinitesimal operations,

$$(X_1,\ \lambda X_2 + \mu X_3) = (\lambda c_{121} + \mu c_{131})X_1 + (\lambda c_{122} + \mu c_{132})X_2 + (\lambda c_{123} + \mu c_{133})X_3.$$

Hence if

$$\mu(\lambda c_{122} + \mu c_{132}) = \lambda(\lambda c_{123} + \mu c_{133}),$$

then X_1 and $\lambda X_2 + \mu X_3$ generate a group of order two. New generators may therefore be taken such that

$$(Y_1Y_2) = aY_1, \text{ where } a \text{ is 0 or 1.}$$

If a were zero the order of the derived group could not exceed two, as it must if the group is simple.

Now if

$$(Y_1Y_2) = Y_1,$$

the identity

$$((Y_1Y_2)Y_3) + ((Y_2Y_3)Y_1) + ((Y_3Y_1)Y_2) = 0$$

gives

$$(c_{131} + c_{232})\ Y_1 + (c_{233} - 1)(Y_1Y_3) + c_{133}(Y_2Y_3) = 0.$$

Hence if

$$c_{133} = 0,$$

then

$$c_{233} = 1,\ c_{131} + c_{232} = 0.$$

Now

$$(Y_2 + xY_1,\ uY_1 + vY_2 + wY_3) = (xv - u + wc_{231} + xwc_{131})Y_1 + w(c_{232} + xc_{132})Y_2 + w(c_{233} + xc_{133})Y_3.$$

Hence if

$$c_{233}+xc_{133}=1,$$
$$w(c_{232}+xc_{132})=v,$$
$$xv+w(c_{231}+xc_{131})=u,$$

then

$$(Y_2+xY_1,\ uY_1+vY_2+wY_3)=uY_1+vY_2+wY_3;$$

and, from the relations obtained above, the equations for x and for the ratios of u, v, w are always capable of finite solution.

If then

$$Y_1=Z_1,\ Y_2+xY_1=Z_2,\ uY_1+vY_2+wY_3=Z_3,$$

we have

$$(Z_1Z_2)=Z_1,\ (Z_2Z_3)=Z_3.$$

Jacobi's identity then gives

$$((Z_1Z_3)Z_2)=0,$$

or

$$(Z_1Z_3)=\alpha Z_2.$$

Moreover, on replacing Z_1 and Z_3 by arbitrary multiples of themselves, α may be made any constant except zero.

There is therefore a single type of simple continuous group of order three, and it is defined by

$$(X_1X_2)=X_1,\ (X_2X_3)=X_3,\ (X_1X_3)=\alpha X_2,$$

where α is any constant other than zero.

A particular form of the group is given by

$$X_1=\frac{d}{dx},\quad X_2=x\frac{d}{dx},\quad X_3=x^2\frac{d}{dx}.$$

In regard to the enumeration and classification of simple continuous groups, it is impossible here to do more than to give the results that have been arrived at. It is very remarkable that this enumeration has been completely carried out, for in the case of groups of finite order such is far from being the case. Lie himself has demonstrated the existence of four great classes of simple groups. These are:—

(i.) The groups simply isomorphic with the general projective group in space of n dimensions. Such a group is defined analytically as the totality of the transformations of the form

$$x'_s=\frac{a_{s,1}x_1+a_{s,2}x_2+\ldots+a_{s,n}x_n+a_{s,n+1}}{a_{n+1,1}x_1+a_{n+1,2}x_2+\ldots+a_{n+1,n}x_n+1},$$
$$(s=1,\ 2,\ldots,\ n),$$

where the a's are parameters. The order of this group is clearly $n(n+2)$.

(ii.) The groups simply isomorphic with the totality of the projective transformations which transform a non-special linear complex in space of $2n-1$ dimensions with itself. The order of this group is $n(2n+1)$.

(iii.) and (iv.) The groups simply isomorphic with the totality of the projective transformations which change a quadric of non-vanishing discriminant into itself. It is found that these fall into two distinct classes of types according as n is even or odd. In either case the order is $\frac{1}{2}n(n+1)$. The case $n=3$ forms an exception in which the corresponding group is not simple. It is also to be noticed that a cyclical group is a simple group, since it has no continuous self-conjugate subgroup distinct from itself.

Killing and Cartan have separately proved the very remarkable fact that outside these four great classes there exist only five distinct types of simple groups, whose orders are 14, 52, 78, 133, and 248; thus completing the enumeration of all possible types.

To prevent any misapprehension as to the bearing of these very general results, it is well to point out explicitly that there are no limitations on the parameters of a continuous group as it has been defined above. They are to be regarded as taking in general complex values. If in the finite equations of a continuous group the imaginary symbol does not explicitly occur, the finite equations will usually define a group (in the general sense of the original definition) when both parameters and variables are limited to real values. Such a group is, in a certain sense, a continuous group; and such groups have been considered shortly by Lie (cf. Lie-Engel, iii. pp. 360–392), who calls them *real* continuous groups. To these real continuous groups the above statement as to the totality of simple groups does not apply; and indeed, in all probability, the number of types of real simple continuous groups admits of no such complete enumeration. The effect of limitation to real transformations may be illustrated by considering the groups of projective transformations which change

$$x^2+y^2+z^2-1=0$$

and

$$x^2+y^2-z^2-1=0$$

respectively into themselves. Since one of these quadrics is changed into the other by the imaginary transformation

$$x'=x,\ y'=y,\ z'=z\sqrt{-1},$$

the general continuous groups which transform the two quadrics respectively into themselves are simply isomorphic. This is not, however, the case for the *real* continuous groups. In fact, the second quadric has two real sets of generators; and therefore the real group which transforms it into itself has two self-conjugate subgroups, either of which leaves unchanged each of one set of generators. The first quadric having imaginary generators, no such self-conjugate subgroups can exist for the real group which transforms it into itself; and this real group is in fact simple.

The adjunct group.

Among the groups isomorphic with a given continuous group there is one of special importance which is known as the *adjunct* group. This is a homogeneous linear group in a number of variables equal to the order of the group, whose infinitesimal operations are defined by the relations

$$X_j=\sum_{i,s}c_{ijs}x_i\frac{\partial}{\partial x_s},$$
$$(j=1,\ 2,\ldots,\ r),$$

where c_{ijs} are the often-used constants, which give the combinants of the infinitesimal operations in terms of the infinitesimal operations themselves.

That the r infinitesimal operations thus defined actually generate a group isomorphic with the given group is most readily verified by forming their combinants. We have

$$\begin{aligned}(X_pX_q)&=\Big(\sum_{i,s}c_{ips}x_i\frac{\partial}{\partial x_s}\Big)\Big(\sum_{j,t}c_{jqt}x_j\frac{\partial}{\partial x_t}\Big)\\&\quad-\Big(\sum_{j,t}c_{jqt}x_j\frac{\partial}{\partial x_t}\Big)\Big(\sum_{i}c_{ips}x_i\frac{\partial}{\partial x_s}\Big)\\&=\sum_{i,t,s}(c_{ips}c_{sqt}+c_{qis}c_{spt})x_i\frac{\partial}{\partial x_t}.\end{aligned}$$

But the c's are subject to the relation

$$\sum_s(c_{ips}c_{sqt}+c_{qis}c_{spt}+c_{pqs}c_{sit})=0$$

for all suffixes i, p, q, and t.

Hence

$$\begin{aligned}(X_pX_q)&=\sum_{i,t,s}c_{pqs}c_{ist}x_i\frac{\partial}{\partial x_t},\\&=\sum_s c_{pqs}X_s,\end{aligned}$$

and therefore the r infinitesimal operations actually generate a group isomorphic with the given group. The X's, however, are not necessarily linearly independent. In fact, the sufficient condition that

$$\sum_j a_j X_j$$

should be identically zero is that

$$\sum_j a_j c_{ijs}$$

should vanish for all values of i and s. Hence if the equations

$$\sum_j a_j c_{ijs} = 0$$

for all values of i and s, have r' linearly independent solutions, only $r-r'$ of the X's are linearly independent, and the isomorphism of the two groups is multiple. If

$$Y_1, Y_2, \ldots, Y_r$$

are the infinitesimal operations of the given group, the equations

$$\sum_j a_j c_{ijs} = 0, \ (s, i = 1, 2, \ldots, r)$$

express the condition that the operations of the cyclical group generated by

$$\sum_j a_j Y_j$$

should be permutable with every operation of the group; in other words, that they should be self-conjugate operations. In the case supposed, therefore, the given group contains a subgroup of order r' each of whose operations is self-conjugate. The adjunct group of a given group will, therefore, be simply isomorphic with the group, unless the latter contains self-conjugate operations; and when this is the case the order of the adjunct will be less than that of the given group by the order of the subgroup formed of the self-conjugate operations.

Continuous groups of the line of the plane, and of three-dimensional space.

We have been thus far mainly concerned with the abstract theory of continuous groups, in which no distinction is made between two simply isomorphic groups. It is now time to give some account of what has been accomplished in the classification and theory of groups when their form is regarded as essential; and this is a return to a more geometrical point of view.

It is natural to begin with the projective groups, which are the simplest in form and at the same time are of supreme importance in geometry. The general projective group of the straight line is the group of order three given by

$$x' = \frac{ax+b}{cx+1}.$$

This group is triply-transitive as regards the points of the line. In fact, if x_1, x_2, x_3 are the co-ordinates of three points on the line

$$\frac{x'_3 - x'_2}{x'_3 - x'_1} \cdot \frac{x' - x'_1}{x' - x'_2} = \frac{x_3 - x_2}{x_3 - x_1} \cdot \frac{x - x_1}{x - x_2}$$

is an equation of the above form which changes x_1, x_2, x_3 into x'_1, x'_2, x'_3.

If $x'_1 = x_1$ and $x'_2 = x_2$, the last written transformation is of the form

$$\frac{x' - x_1}{x' - x_2} = a\frac{x - x_1}{x - x_2},$$

and when a is regarded as a parameter, the totality of transformations of this form, x_1 and x_2 being given distinct points, forms a cyclical group. The totality of the transformations which keep two distinct points fixed constitutes therefore a cyclical subgroup. When the fixed points are 0 and ∞, the form of this subgroup is

$$x' = ax,$$

and all such subgroups are clearly conjugate within the general group.

When x_2 is infinite and x_1 an arbitrarily assigned point, the form of the subgroup is

$$x' = ax + (1-a)x_1;$$

and if here x_1 approaches ∞, and b is written for the limit of $(1-a)x_1$, so that a must approach unity, the limiting form is

$$x' = x + b.$$

The totality of the transformations which keep two coincident points fixed forms, therefore, again a cyclical subgroup, which, when the fixed double point is at infinity, has the last given form. All such subgroups again are conjugate.

If in

$$\frac{x'_3 - x'_2}{x'_3 - x'_1} \frac{x' - x'_1}{x' - x'_2} = \frac{x_3 - x_2}{x_3 - x_1} \frac{x - x_1}{x - x_2}.$$

$$x_2 = x'_2 = \infty$$

the transformation has the form

$$x' = ax + b,$$

and transformations of this form, where a and b are parameters, constitute a group of order two. Hence the totality of the transformations, which keep a single point fixed, constitutes a subgroup of order two; such subgroups form a single conjugate set; and when the fixed point is at infinity the subgroup has the last written form.

A group of order two is not simple, and therefore every subgroup of order two of the general projective group of the straight line must contain a cyclical group as a self-conjugate subgroup. Every subgroup of order two must therefore keep at least one point fixed, namely, the fixed point of its self-conjugate cyclical subgroup. Hence the subgroups above determined exhaust all the subgroups of the projective group of the line.

The analysis of the general projective group must obviously increase very rapidly in complexity, as the dimensions of the space to which it applies increase. This analysis has been completely carried out for the projective group of the plane, with the result of showing that there are thirty distinct types of subgroup. Excluding the general group itself, every one of these leaves either a point, a line, or a conic section unaltered. For space of three dimensions Lie has also carried out a similar investigation, but the results are extremely complicated. One general result of great importance at which Lie arrives in this connexion is that every projective group in space of three dimensions, other than the general group, leaves either a point, a curve, a surface, or a linear complex unaltered.

For space of more than three dimensions, it is only certain special types of projective groups which have been hitherto investigated. For instance, Lie has determined those projective groups in n variables whose degree of transitivity is as great as possible.

Returning now to the case of a single variable, it can be shown that any finite continuous group in one variable is either cyclical or of order two or three, and that by a suitable transformation any such group may be changed into a projective group.

The genesis of an infinite as distinguished from a finite continuous group may be well illustrated by considering it in the case of a single variable. The infinitesimal operations of the projective group in one variable are

$$\frac{d}{dx}, \ x\frac{d}{dx}, \ x^2\frac{d}{dx}.$$

If these combined with

$$x^3\frac{d}{dx}$$

be taken as infinitesimal operations from which to generate a continuous group among the infinitesimal operations of the group, there must occur the combinant of $x^2\frac{d}{dx}$ and $x^3\frac{d}{dx}$. This is $x^4\frac{d}{dx}$. The combinant of this and $x^2\frac{d}{dx}$ is

$2x^5\frac{d}{dx}$ and so on. Hence $x^r\frac{d}{dx}$, where r is any positive integer, is an infinitesimal operation of the group. The general infinitesimal operation of the group is therefore $f(x)\frac{d}{dx}$ where $f(x)$ is an arbitrary integral function of x.

In the classification of the groups, projective or non-projective, of two or more variables, the distinction between primitive and imprimitive groups immediately presents itself. For groups of the plane the question that then arises is the following. Is there or is there not a singly-infinite family of curves

$$f(x, y) = C,$$

where C is an arbitrary constant such that every operation of the group interchanges the curves of the family among themselves? In accordance with the previously given definition of imprimitivity, the group is called imprimitive or primitive according as such a set exists or not. In space of three dimensions there are two possibilities; namely, there may either be a singly infinite system of surfaces

$$F(x, y, z) = C$$

which are interchanged among themselves by the operations of the group; or there may be a doubly-infinite system of curves

$$G(x, y, z) = a,\ H(x, y, z) = b,$$

which are so interchanged.

In regard to primitive groups Lie has shown that any primitive group of the plane can, by a suitably chosen transformation, be transformed into one of three definite types of projective groups; and that any primitive group of space of three dimensions can be transformed into one of eight definite types, which, however, cannot all be represented as projective groups in three dimensions.

The results which have been arrived at for imprimitive groups in two and three variables do not admit of any such simple statement; but in this case, again, the classification is complete in the sense that all possible types are divided into a number of classes, while methods are given which enable the complete determination of the groups belonging to a given class to be carried out.

No account of the theory of continuous groups would be complete without some reference, however short, to the conception of contact-transformations and groups of contact-transformations. This conception, like that of continuous groups, owes its origin to the genius of Sophus Lie.

Contact-transformations

From a purely analytical point of view a contact-transformation may be defined as a point-transformation in $2n+1$ variables, $z, x_1, x_2, \ldots, x_n, p_1, p_2, \ldots, p_n$ which leaves unaltered the equation

$$dz - p_1dx_1 - p_2dx_2 - \ldots - p_ndx_n = 0.$$

Such a definition as this, however, gives no direct clue to the geometrical properties of the transformation, nor does it explain the name given.

In dealing with contact-transformations we shall restrict ourselves to space of two or of three dimensions; and it will be necessary to begin with some purely geometrical considerations. An infinitesimal surface-element in space of three dimensions is completely specified, apart from its size, by its position and orientation. If x, y, z are the co-ordinates of some one point of the element, and if $p, q, -1$ give the ratios of the direction-cosines of its normal, x, y, z, p, q are five quantities which completely specify the element. There are, therefore, ∞^5 surface elements in three-dimensional space. The surface-elements of a surface form a system of ∞^2 elements, for there are ∞^2 points on the surface, and at each a definite surface-element. The surface-elements of a curve form, again, a system of ∞^2 elements, for there are ∞^1 points on the curve, and at each ∞^1 surface-elements containing the tangent to the curve at the point. Similarly the surface-elements which contain a given point clearly form a system of ∞^2 elements. Now each of these systems of ∞^2 surface-elements has the property that if (x, y, z, p, q) and $(x+dx,\ y+dy,\ z+dz,\ p+dp,\ q+dq)$ are consecutive elements from any one of them, then

$$dz - pdx - qdy = 0.$$

In fact, for a system of the first kind dx, dy, dz are proportional to the direction-cosines of a tangent line at a point of the surface, and p, q, -1 are proportional to the direction-cosines of the normal. For a system of the second kind dx, dy, dz are proportional to the direction-cosines of a tangent to the curve, and p, q, -1 give the direction-cosines of the normal to a plane touching the curve; and for a system of the third kind dx, dy, dz are zero. Now the most general way in which a system of ∞^2 surface-elements can be given is by three independent equations between x, y, z, p and q. If these equations do not contain p, q, they determine one or more (a finite number in any case) points in space, and the system of surface-elements consists of the elements containing these points; *i.e.*, it consists of one or more systems of the third kind.

If the equations are such that two distinct equations independent of p and q can be derived from them, the points of the system of surface-elements lie on a curve. For such a system the equation

$$dz - pdx - qdy = 0$$

will hold for each two consecutive elements only when the plane of each element touches the curve at its own point.

If the equations are such that only one equation independent of p and q can be derived from them, the points of the system of surface-elements lie on a surface. Again, for such a system the equation

$$dz - pdx - qdy = 0$$

will hold for each two consecutive elements only when each element touches the surface at its own point. Hence, when all possible systems of ∞^2 surface-elements in space are considered, the equation

$$dz - pdx - qdy = 0,$$

is characteristic of the three special types in which the elements belong, in the sense explained above, to either a point, a curve, or a surface.

Let us consider now the geometrical bearing of any transformation

$$x' = f_1(x, y, z, p, q), \ldots, q' = f_5(x, y, z, p, q),$$

of the five variables. It will interchange the surface-elements of space among themselves, and will change any system of ∞^2 elements into another system of ∞^2 elements. A special system, *i.e.*, a system which belongs to a point, curve, or surface, will not, however, in general be changed into another special system. The necessary and sufficient condition that a special system should always be changed into a special system is that the equation

$$dz' - p'dx' - q'dy' = 0$$

should be a consequence of the equation

$$dz - pdx - qdy = 0;$$

or, in other words, that this latter equation should be invariant for the transformation.

When this condition is satisfied the transformation is such as to change the surface-elements of a surface in general into surface-elements of a surface, though in particular cases they may become the surface-elements of

a curve or point; and similar statements may be made with respect to a curve or point. The transformation is therefore a veritable geometrical transformation in space of three dimensions. Moreover, two special systems of surface-elements which have an element in common are transformed into two new special systems with an element in common. Hence two curves or surfaces which touch each other are transformed into two new curves or surfaces which touch each other. It is this property which leads to the transformations in question being called contact-transformations. It will be noticed that an ordinary point-transformation is always a contact-transformation, but that a contact-transformation (in space of n dimensions) is not in general a point-transformation (in space of n dimensions), though it may always be regarded as a point-transformation in space of $2n+1$ dimensions. In the analogous theory for space of two dimensions a line-element, defined by (x, y, p), where $1:p$ gives the direction-cosines of the line, takes the place of the surface-element; and a transformation of x, y, and p which leaves the equation

$$dy - pdx = 0$$

unchanged transforms the ∞^1 line-elements, which belong to a curve, into ∞^1 line-elements which again belong to a curve; while two curves which touch are transformed into two other curves which touch.

One of the simplest instances of a contact-transformation that can be given is the transformation by reciprocal polars. By this transformation a point P and a plane p passing through it are changed into a plane p' and a point P′ upon it; *i.e.*, the surface-element defined by P, p is changed into a definite surface-element defined by P′, p'. The totality of surface-elements which belong to a (non-developable) surface is known from geometrical considerations to be changed into the totality which belongs to another (non-developable) surface. On the other hand, the totality of the surface-elements which belong to a curve is changed into another set which belong to a developable. The analytical formulæ for this transformation, when the reciprocation is effected with respect to the paraboloid $x^2+y^2-2z=0$, are

$$x'=p,\ y'=q,\ z'=px+qy-z,\ p'=x,\ q'=y.$$

That this is, in fact, a contact-transformation is verified directly by noticing that

$$\begin{aligned} dz'-p'dx'-q'dy' &= -d(z-px-qy)-xdp-ydq \\ &= -(dz-pdx-qdy). \end{aligned}$$

A second simple example is that in which every surface-element is displaced, without change of orientation, normal to itself through a constant distance t. The analytical equations in this case are easily found in the form

$$x'=x+\frac{pt}{\sqrt{1+p^2+q^2}},\quad y'=y+\frac{qt}{\sqrt{1+p^2+q^2}},\quad z'=z-\frac{t}{\sqrt{1+p^2+q^2}},$$
$$p'=p,\ q'=q.$$

That this is a contact-transformation is seen geometrically by noticing that it changes a surface into a parallel surface. Every point is changed by it into a sphere of radius t. Also from the analytical form of the transformation, it follows at once that

$$dz'-p'dx'-q'dy'=dz-pdx-qdy.$$

The symbol of a general infinitesimal operation in the five variables x, y, z, p, q is

$$\zeta\frac{\partial}{\partial z}+\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}+\pi\frac{\partial}{\partial p}+\kappa\frac{\partial}{\partial q},$$

where $\xi, \eta, \zeta, \pi, \kappa$, are functions of the variables.

The increment of

$$dz-pdx-qdy$$

given by this infinitesimal operation is

$$(d\zeta-\pi dx-pd\xi-\kappa dy-qd\eta)\delta t.$$

Hence the necessary and sufficient condition that the transformation should be a contact-transformation in space (x, y, z) is

$$d\zeta-\pi dx-pd\xi-\kappa dy-qd\eta=\sigma(dz-pdx-qdy),$$

where σ is some function of x, q, z, q, q.

This equation is equivalent to

$$\frac{\partial}{\partial z}(\zeta-p\xi-q\eta)=\sigma,$$
$$\frac{\partial}{\partial x}(\zeta-p\xi-q\eta)=\pi-\sigma p,$$
$$\frac{\partial}{\partial y}(\zeta-p\xi-q\eta)=\kappa-\sigma q,$$
$$\frac{\partial}{\partial p}(\zeta-p\xi-q\eta)=-\xi,$$
$$\frac{\partial}{\partial q}(\zeta-p\xi-q\eta)=-\eta.$$

Hence if

$$p\xi+q\eta-\zeta=\omega,$$
$$\xi=\frac{\partial\omega}{\partial p},\ \eta=\frac{\partial\omega}{\partial q},\ \pi=-\frac{\partial\omega}{\partial x}-p\frac{\partial\omega}{\partial z},\ \kappa=-\frac{\partial\omega}{\partial y}-q\frac{\partial\omega}{\partial z}$$
$$\zeta=p\frac{\partial\omega}{\partial p}+q\frac{\partial\omega}{\partial q}-\omega,$$

where the function ω is quite arbitrary. If ω is zero the transformation is the identical transformation, but for any value of ω other than zero an actual transformation distinct from identity arises. Every infinitesimal contact-transformation is thus completely defined by a function ω of the variables, which is called its characteristic function. It will be noticed that ξ, η and ζ are independent of p and q if, and only if, ω is linear in p and q. In these cases only is the transformation an ordinary point-transformation.

If

$$\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}+\zeta\frac{\partial}{\partial z}$$

is an infinitesimal point-transformation in three-dimensional space, so that ξ, η, ζ are functions of x, y, z only, the characteristic function for the transformation regarded as a contact-transformation is

$$p\xi+q\eta-\zeta.$$

Hence

$$\pi=\frac{\partial\zeta}{\partial x}+p\left(\frac{\partial\zeta}{\partial z}-\frac{\partial\xi}{\partial x}\right)-q\frac{\partial\eta}{\partial x}-pq\frac{\partial\eta}{\partial z}-p^2\frac{\partial\xi}{\partial z},$$
$$\kappa=\frac{\partial\zeta}{\partial y}-p\frac{\partial\xi}{\partial y}+q\left(\frac{\partial\zeta}{\partial z}-\frac{\partial\eta}{\partial y}\right)-pq\frac{\partial}{\partial z}-q^2\frac{\partial\eta}{\partial z},$$

and these expressions give the infinitesimal changes that arise in p and q from the point-transformation. As a transformation of the five variables the point-transformation may be written

$$\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}+\zeta\frac{\partial}{\partial z}+\pi\frac{\partial}{\partial p}+\kappa\frac{\partial}{\partial q},$$

and this is called the *extended* point-transformation.

Since a contact-transformation in space of n dimensions may be regarded as a point-transformation in space of $2n+1$ dimensions, which leaves invariant the equation

$$dz-pdx,-\ldots-p_n dx_n=0,$$

two contact-transformations carried out in succession give rise to another contact-transformation. Hence arises naturally the conception of a group of contact-transformations. Thus the totality of the transformations that arise on repeating an infinitesimal contact-transformation constitutes a (continuous) cyclical group. For example, if the characteristic function of the infinitesimal transformation is $\sqrt{1+p^2+q^2}$, the finite equations of the resulting cyclical group are

$$x' = x + \frac{pt}{\sqrt{1+p^2+q^2}},\ y' = y + \frac{qt}{\sqrt{1+p^2+q^2}},\ z' = z - \frac{t}{\sqrt{1+p^2+q^2}},$$
$$p' = p, \quad q' = q;$$

where t is the arbitrary parameter.

The formal theory of continuous groups of contact-transformations is, of course, in no way distinct from the formal theory of continuous groups in general. On what may be called the geometrical side, the theory of groups of contact-transformations has been developed with very considerable detail in the second volume of Lie-Engel; and to this work the reader may be referred. As an example of the way in which a continuous group may be defined by a system of differential equations we will conclude the present section by the determination of those contact-transformations in the plane for which the equation

$$\frac{d^3y}{dx^3} = 0$$

is invariant. Let

$$\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y} + \omega\frac{\partial}{\partial p}$$

be an infinitesimal contact-transformation, and let $\kappa\tau$ and $\rho\tau$, where τ is infinitesimal, be the increments of $\frac{d^2y}{dx^2}$ and $\frac{d^3y}{dx^3}$, or of q and r. Then

$$q + \kappa\tau = \frac{d(p+\omega\tau)}{d(x+\xi\tau)}$$
$$= q + (\omega_x + \omega_y p + \omega_p q - \xi_x q - \xi_y pq - \xi_p q^2)\tau,$$

or

$$\kappa = \omega_x + \omega_y p + \omega_p q - \xi_x q - \xi_y pq - \xi_p q^2,$$

where the suffixes denote partial differentiation. So

$$r + \rho\tau = \frac{d(q+\kappa\tau)}{d(x+\xi\tau)},$$

and

$$\rho = \kappa_x + \kappa_y p + \kappa_p q + \kappa_q r - \xi_x r - \xi_y rp - \xi_p rq.$$

If the equation

$$r = 0$$

is to be invariant for the given infinitesimal transformation, then $\rho = 0$ must be a consequence of $r = 0$. Hence

$$\kappa_x + \kappa_y p + \kappa_p q = 0.$$

In this equation the coefficient of each power of q must vanish. Hence

$$\xi_{pp} = 0,\ \omega_{xx} + 2p\omega_{xy} + p^2\omega_{yy} = 0,$$
$$\omega_y + 2\omega_{xp} + 2p\omega_{yp} - \xi_{xx} - 2p\xi_{xy} - p^2\xi_{yy} = 0,$$
$$-\xi_y + \omega_{pp} - 2\xi_{xp} - 2p\xi_{yp} = 0.$$

If W is the characteristic function of the infinitesimal transformation, then

$$\xi = \mathrm{W}_p,\ \omega = -\mathrm{W}_x - p\mathrm{W}_y;$$

and when expressed in terms of W the four equations become

$$\frac{\partial^3\mathrm{W}}{\partial p^3} = 0,\ \left(\frac{\partial}{\partial x} + p\frac{\partial}{\partial y}\right)^3\mathrm{W} = 0,$$
$$\frac{\partial^2\mathrm{W}}{\partial y\partial p} + \left(\frac{\partial}{\partial x} + p\frac{\partial}{\partial y}\right)\frac{\partial^2\mathrm{W}}{\partial p^2} = 0,$$
$$\left(\frac{\partial}{\partial x} + p\frac{\partial}{\partial y}\right)\frac{\partial}{\partial p}\left(\frac{\partial}{\partial x} + p\frac{\partial}{\partial y}\right)\mathrm{W} = 0.$$

From the first and third of these equations it immediately follows that

$$\mathrm{W} = \tfrac{1}{2}p^2\mathrm{X}_1 + p\left(\mathrm{X}_2 - y\frac{d\mathrm{X}_1}{dx}\right) + f(x, y),$$

where X_1 and X_2 are functions of x only. The fourth equation then gives

$$f(x, y) = y^2\frac{d^2\mathrm{X}_1}{dx^2} + y\mathrm{X}_3 + \mathrm{X}_4,$$

and the second equation leads to

$$\frac{d^3\mathrm{X}_1}{dx^3} = 0,\ \frac{d^3\mathrm{X}_2}{dx^3} = 0,\ \frac{d^3\mathrm{X}_4}{dx^3} = 0,\ \frac{d\mathrm{X}_3}{dx} + \frac{d^2\mathrm{X}_2}{dx^2} = 0.$$

Hence W contains ten arbitrary constants, and in fact it is found on completing the calculation that W is an arbitrary integral function of the second degree of x, p, and $y - \frac{1}{2}px$.

The most general infinitesimal contact-transformation, for which the equation $r = 0$ is invariant, therefore contains 10 arbitrary constants; and the totality of such operations constitutes a continuous group of order 10. It should be noticed that that part of ω which does not contain p^2 has 7 arbitrary constants, so that the greatest group of point-transformations in the plane for which $r = 0$ is invariant has 7 for its order.

Applications of the theory of continuous groups.

To the manifold applications of the theory of continuous groups in various branches of pure and applied mathematics it is impossible here to refer in any detail. It must suffice to indicate a few of them very briefly. In some of the older theories a new point of view is obtained which presents the results in a fresh light, and suggests the natural generalization. As an example, the theory of the invariants of a binary form may be considered.

If in the form

$$f = a_0x^n + na_1x^{n-1}y + \dots + a_ny^n,$$

the variables be subjected to a homogeneous substitution

$$x' = \alpha x + \beta y, \quad y' = \gamma x + \delta y, \qquad \text{(i.)}$$

and if the coefficients in the new form be represented by accenting the old coefficients, then

$$\left.\begin{aligned} a'_0 &= a_0\alpha^n + a_1n\alpha^{n-1}\gamma + \dots + a_n\gamma^n, \\ a'_1 &= a_0\alpha^{n-1}\beta + a_1(\overline{n-1}\,\alpha^{n-2}\beta\gamma + \alpha^{n-1}\delta) + \dots + a_n\gamma^{n-1}\delta, \\ &\cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \\ a'_n &= a_0\beta^n + a_1n\beta^{n-1}\delta + \dots + a_n\delta^n; \end{aligned}\right\}\text{(ii.)}$$

and this is a homogeneous linear substitution performed on the coefficients. The totality of the substitutions (i.), for which $\alpha\delta - \beta\gamma = 1$, constitutes a continuous group of order 3, which is generated by the two infinitesimal transformations

$$y\frac{\partial}{\partial x} \text{ and } x\frac{\partial}{\partial y}.$$

Hence with the same limitations on α, β, γ, δ the totality of the substitutions (ii.) forms a simply isomorphic continuous group of order 3, which is generated by the two infinitesimal transformations

$$a_0\frac{\partial}{\partial a_1} + 2a_1\frac{\partial}{\partial a_2} + 3a_2\frac{\partial}{\partial a_3} + \dots + na_{n-1}\frac{\partial}{\partial a_n},$$

and

$$na_1\frac{\partial}{\partial a_0} + \overline{n-1}\,a_2\frac{\partial}{\partial a_1} + \overline{n-2}\,a_3\frac{\partial}{\partial a_2} + \dots + a_n\frac{\partial}{\partial a_{n-1}}.$$

The invariants of the binary form, *i.e.*, those functions of the coefficients which are unaltered by all homogeneous substitutions on x, y of determinant unity, are therefore identical with the functions of the coefficients which are invariant for the continuous group generated by the two infinitesimal operations last written. In other words, they are given by the common solutions of the differential equations

$$a_0\frac{\partial f}{\partial a_1} + 2a_1\frac{\partial f}{\partial a_2} + 3a_2\frac{\partial f}{\partial a_3} + \dots = 0,$$
$$na_1\frac{\partial f}{\partial a_0} + \overline{n-1}\,a_2\frac{\partial f}{\partial a_1} + \overline{n-2}\,a_3\frac{\partial f}{\partial a_2} + \dots = 0.$$

Both this result and the method by which it is arrived at are well known, but the point of view by which we pass from the transformation group of the variables to the isomorphic transformation group of the coefficients, and regard the invariants as invariants rather of the group than of the forms, is a new and a fruitful one.

The general theory of curvature of curves and surfaces may in a similar way be regarded as a theory of their

invariants for the group of motions. That something more than a mere change of phraseology is here implied will be evident in dealing with minimum curves, *i.e.*, with curves such that at every point of them

$$dx^2 + dy^2 + dz^2 = 0.$$

For such curves the ordinary theory of curvature has no meaning, but they nevertheless have invariant properties in regard to the group of motions.

The curvature and torsion of a curve, which are invariant for all transformations by the group of motions, are special instances of what are known as *differential invariants*. If

$$\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}$$

is the general infinitesimal transformation of a group of point-transformations in the plane, it has been already seen how to extend the transformation so as to indicate its effect on the successive differential coefficients $y_1, y_2, \ldots$ of y. If

$$\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y} + \eta_1 \frac{\partial}{\partial y_1} + \eta_2 \frac{\partial}{\partial y_2} + \cdots$$

be the extended transformation, it may be regarded as a transformation of the variables

$$x, y, y_1, y_2, \ldots$$

By including a sufficient number of these variables the group must be intransitive in them, and must therefore have one or more invariants. Such invariants are known as differential invariants of the original group, being necessarily functions of the differential coefficients of the original variables. For groups of the plane it may be shown that not more than two of these differential invariants are independent, all others being formed from these by algebraical processes and differentiation. For groups of point-transformations in more than two variables there will be more than one set of differential invariants. For instance, with three variables, one may be regarded as independent, and the other two as functions of it, or two as independent and the remaining one as a function. Corresponding to these two points of view, the differential invariants for a curve or for a surface will arise.

If a differential invariant of a continuous group of the plane be equated to zero, the resulting differential equation remains unaltered when the variables undergo any transformation of the group. Conversely, if an ordinary differential equation

$$f(x, y, y_1, y_2, \ldots) = 0$$

admits the transformations of a continuous group, *i.e.*, if the equation is unaltered when x and y undergo any transformation of the group, then $f(x, y, y_1, y_2, \ldots)$ or some multiple of it must be a differential invariant of the group. Hence it must be possible to find two independent differential invariants α, β of the group, such that when these are taken as variables the differential equation takes the form

$$\mathrm{F}\left(\alpha, \beta, \frac{d\beta}{d\alpha}, \frac{d^2\beta}{d\alpha^2}, \ldots\right) = 0.$$

This equation in α, β will be of lower order than the original equation, and in general simpler to deal with. Supposing it solved in the form

$$\beta = \phi(\alpha),$$

where for α, β their values in terms of $x, y, y_1, y_2, \ldots$ are written, this new equation, containing arbitrary constants, is necessarily again of lower order than the original equation. The integration of the original equation is thus divided into two steps. This will show how, in the case of an ordinary differential equation, the fact that the equation admits a continuous group of transformations may be taken advantage of for its integration.

The most important of the applications of continuous groups are to the theory of systems of differential equations, both ordinary and partial; in fact, Lie states that it was with a view to systematizing and advancing the general theory of differential equations that he was led to the development of the theory of continuous groups. It is quite impossible here to give any account of all that Lie and his followers have done in this direction. An entirely new mode of regarding the problem of the integration of a differential equation has been opened up, and in the classification that arises from it all those apparently isolated types of equations which in the older sense are said to be integrable take their proper place. It may, for instance, be mentioned that the question as to whether Monge's method will apply to the integration of a partial differential equation of the second order is shown to depend on whether or not a contact-transformation can be found which will reduce the equation to either

$$\frac{\partial^2 z}{\partial x^2} = 0 \text{ or } \frac{\partial^2 z}{\partial x \partial y} = 0.$$

It is in this direction that further advance in the theory of partial differential equations must be looked for. Lastly, it may be remarked that one of the most thorough discussions of the axioms of geometry hitherto undertaken is founded entirely upon the theory of continuous groups.

Discontinuous Groups.

We go on now to the consideration of discontinuous groups. Although groups of finite order are necessarily contained under this general head, it is convenient for many reasons to deal with them separately, and it will therefore be assumed in the present section that the number of operations in the group is not finite. Many large classes of discontinuous groups have formed the subject of detailed investigation, but a general formal theory of discontinuous groups can hardly be said to exist as yet. For instance, there is in this connexion no system of theorems concerning possible types of simple groups analogous to those stated above for continuous groups. In fact no discontinuous group (with a finite number of independent generating operations), whose order is not finite, has yet been recognized as a simple group; though, on the other hand, the non-existence of such simple discontinuous groups, if true, has still to be demonstrated. It will thus be obvious that in considering discontinuous groups it is necessary to proceed on different lines from those followed with continuous groups, and in fact to deal with the subject almost entirely by way of example. An operation of a discontinuous group must necessarily be specified analytically by a system of equations of the form

$$x'_s = f_s(x_1, x_2, \ldots, x_n;\ a_1, a_2, \ldots, a_r) \qquad \text{(i.)}$$
$$(s = 1, 2, \ldots, n),$$

Properly and improperly discontinuous groups.

and the different operations of the group will be given by different sets of values of the parameters $a_1, a_2, \ldots, a_r$. No one of these parameters is susceptible of continuous variations, but at least one must be capable of taking a number of values which is not finite, if the group is not one of finite order. If $b_1, b_2, \ldots, b_r$ is another set of values of the parameters, then the result of eliminating $x'_1, x'_2, \ldots, x'_n$ between (i.) and

$$x''_s = f_s(x'_1, x'_2, \ldots, x'_n;\ b_1, b_2, \ldots, b_r)$$
$$(s = 1, 2, \ldots, n)$$

must lead to

$$x''_s = f_s(x_1, x_2, \ldots, x_n;\ c_1, c_2, \ldots, c_r),$$
$$(s = 1, 2, \ldots, n),$$

where $c_1, c_2, \ldots, c_r$ is a third set of admissible values of the parameters. Among the sets of values of the para-

meters there must be one which gives the identical transformation. No other transformation makes each of the differences $x'_1 - x_1$, $x'_2 - x_2, \ldots, x'_n - x_n$ vanish. Let d be an arbitrary assigned positive quantity. Then if a transformation of the group can be found such that the modulus of each of these differences is less than d when the variables have arbitrary values within an assigned range of variation, however small d may be chosen, the group is said to be *improperly* discontinuous. In the contrary case the group is called *properly* discontinuous. The range within which the variables are allowed to vary may clearly affect the question whether a given group is properly or improperly discontinuous. For instance, the group defined by the equation

$$x' = ax + b,$$

where a and b are any rational numbers, is improperly discontinuous; and the group defined by

$$x' = x + a,$$

where a is an integer, is properly discontinuous, whatever the range of the variable. On the other hand, the group, to be later considered, defined by the equation

$$x' = \frac{ax+b}{cx+d},$$

where a, b, c, d are integers satisfying the relation

$$ad - bc = 1,$$

is properly discontinuous when x may take any complex value, and improperly discontinuous when the range of x is limited to real values.

Among the discontinuous groups that occur in analysis, a large number may be regarded as arising by imposing limitations on the range of variation of the parameters of continuous groups. If

$$x'_s = f_s(x_1, x_2, \ldots, x_n; a_1, a_2, \ldots, a_r), \quad \text{(i.)}$$
$$(s = 1, 2, \ldots, n),$$

are the finite equations of a continuous group, and if C with parameters $c_1, c_2, \ldots, c_r$ is the operation which results from carrying out A and B with corresponding parameters in succession, then the c's are determined uniquely by the a's and the b's. If the c's are rational functions of the a's and b's, and if the a's and b's are arbitrary rational numbers of a given corpus (see NUMBER), the c's will be rational numbers of the same corpus. If the c's are rational integral functions of the a's and b's, and the latter are arbitrarily chosen integers of a corpus, then the c's are integers of the same corpus. Hence in the first case the equations (i.), when the a's are limited to be rational numbers of a given corpus, will define a discontinuous group; and in the second case they will define such a group when the a's are further limited to be integers of the corpus. A most important class of discontinuous groups are those that arise in this way from the general linear continuous group in a given set of variables. For n variables the finite equations of this continuous group are

Linear discontinuous groups.

$$x'_s = a_{s1}x_1 + a_{s2}x_2 + \ldots + a_{sn}x_n, \quad \text{(ii.)}$$
$$(s = 1, 2, \ldots, n),$$

where the determinant of the a's must not be zero. In this case the c's are clearly integral lineo-linear functions of the a's and b's. Moreover, the determinant of the c's is the product of the determinant of the a's and the determinant of the b's. Hence equations (ii.), where the parameters are restricted to be integers of a given corpus, define a discontinuous group; and if the determinant of the coefficients is limited to the value unity, they define a discontinuous group which is a (self-conjugate) subgroup of the previous one.

The simplest case which thus presents itself is that in which there are two variables while the coefficients are rational integers. This is the group defined by the equations

$$\left.\begin{aligned} x' &= ax + by, \\ y' &= cx + dy, \end{aligned}\right\} \quad \text{(iii.)}$$

where a, b, c, d are integers such that

$$ad - bc = 1.$$

To every operation of this group there corresponds an operation of the set defined by

$$z' = \frac{az+b}{cz+d}, \quad \text{(iv.)}$$

in such a way that to the product of two operations of the group there corresponds the product of the two analogous operations of the set. The operations of the set (iv.), where $ad - bc = 1$, therefore constitute a group which is isomorphic with the previous group. The isomorphism is multiple, since to a single operation of the second set there correspond the two operations of the first for which a, b, c, d and $-a$, $-b$, $-c$, $-d$ are parameters. These two groups, which are of fundamental importance in the theory of quadratic forms and in the theory of modular functions, have been the object of very many investigations. From the present point of view they may be used to illustrate how, by further limitations on the parameters, subgroups of a discontinuous group arise.

If a'', b'', c'', d'' are the parameters of the operation which results from carrying out in succession those with parameters a, b, c, d and a', b', c', d', then

$$\begin{aligned} a'' &= aa' + b'c, \\ b'' &= a'b + b'd, \\ c'' &= ac' + cd', \\ d'' &= bc' + dd'. \end{aligned}$$

Hence if

$$a \equiv d \equiv a' \equiv d' \equiv 1, \text{ mod. } n$$
$$b \equiv c \equiv b' \equiv c' \equiv 0,$$

then

$$a'' \equiv d'' \equiv 1,\ b'' \equiv c'' \equiv 0, \text{ mod. } n.$$

The totality of the operations of either group for which a and d are congruent to unity, while b and c are congruent to zero, mod. n, therefore constitutes a subgroup; and it is easy to verify that this subgroup is a self-conjugate subgroup. Again, the totality of the operations for which b is zero constitutes a subgroup; as also do those for which c is zero. These are not self-conjugate subgroups.

Another point of fundamental importance in connexion with discontinuous groups may be illustrated by the groups here under consideration. For each of them a pair of operations may be found such that every operation of the group can be formed by the combination and repetition of the two. It may, in fact, be easily verified that

Generating operations.

$$\begin{aligned} x' &= x + y, \\ y' &= y, \end{aligned} \quad \text{and} \quad \begin{aligned} x' &= -y, \\ y' &= x, \end{aligned}$$

is such a pair of operations for the first group, while

$$z' = z + 1, \text{ and } z' = -\frac{1}{z},$$

is the corresponding pair for the second. As has been already stated, such a set of operations is called a set of generating operations for the group; and when, as in the present instance, no one of them can be formed from the remaining ones, the generating operations are said to be independent. Such a set of necessity exists for every discontinuous group, but their number is not necessarily finite. Moreover, except in the case of a cyclical group, which is formed by the repetition of a single operation, such a set of generating operations is

never unique; for if A, B, C,... generate the group, so also do either A, AB, AC,... ; or $S^{-1}AS$, $S^{-1}BS$, $S^{-1}CS$,... where S is any operation of the group.

The consideration of a discontinuous group as arising from a set of independent generating operations suggests a purely abstract point of view in which any two simply isomorphic groups are indistinguishable. The number of generating operations may be either finite or infinite, but the former case alone will be here considered. Suppose then that

$$S_1, S_2, \ldots, S_n$$

is a set of independent operations from which a group G is generated. The general operation of the group will be represented by the symbol

$$S_a^\alpha S_b^\beta \ldots S_d^\delta, \text{ or } \Sigma,$$

where $a, b, \ldots, d$ are chosen from $1, 2, \ldots, n$, and $\alpha, \beta, \ldots, \delta$ are any positive or negative integers. It may be assumed that no two successive suffixes in Σ are the same, for if $b=a$, then $S_a^\alpha S_b^\beta$ may be replaced by $S_a^{\alpha+\beta}$. If there are no relations connecting the generating operations and the identical operation, every distinct symbol Σ represents a distinct operation of the group. For if

$$\Sigma = \Sigma_1,$$

or

$$S_a^\alpha S_b^\beta \ldots S_d^\delta = S_{a_1}^{\alpha_1} S_{b_1}^{\beta_1} \ldots S_{d_1}^{\delta_1},$$

then

$$S_{d_1}^{-\delta_1} \ldots S_{b_1}^{-\beta_1} S_{a_1}^{-\alpha_1} S_a^\alpha S_b^\beta \ldots S_d^\delta = 1\ ;$$

and unless

$$\begin{matrix} a=a_1, & b=b_1, \\ \alpha=\alpha_1, & \beta=\beta_1, \end{matrix} \ \&c.,$$

this is a relation connecting the generating operations.

Suppose now that $T_1, T_2, \ldots$ are operations of G, and that H is that self-conjugate subgroup of G which is generated by $T_1, T_2, \ldots$ and the operations conjugate to them. Then, of the operations that can be formed from

$$S_1, S_2, \ldots, S_n,$$

the set ΣH, and no others, reduce to the same operation Σ when the conditions

$$T_1 = 1,\ T_2 = 1, \ldots$$

are satisfied by the generating operations. Hence the group which is generated by the given operations, when subjected to the conditions just written, is simply isomorphic with the factor-group G/H. Moreover, this is obviously true even when the conditions are such that the generating operations are no longer independent. Hence any discontinuous group may be defined abstractly, that is, in regard to the laws of combination of its operations apart from their actual form, by a set of generating operations and a system of relations connecting them. Conversely, when such a set of operations and system of relations are given arbitrarily they define in abstract form a single discontinuous group. It may, of course, happen that the group so defined is a group of finite order, or that it reduces to the identical operation only; but in regard to the general statement these will be particular and exceptional cases.

As an example of this abstract mode of defining a group, the group generated by

$$z' = z + 1,\ z' = -\frac{1}{z}$$

may be considered. If these operations are represented by S_1 and S_2, the operation S_1S_2 or

$$z' = \frac{-1}{z+1}$$

is an operation of order three; while S_2 itself is an operation of order two. Among the relations which S_1 and S_2 must satisfy, there must therefore occur

$$(S_1S_2)^3 = 1,\ S_2{}^2 = 1\ ;$$

and these are in fact sufficient. The proof of this statement will occur more naturally later.

We shall now proceed to consider shortly certain special classes of discontinuous groups which occur in plane geometry, and in the theory of functions of a single variable. In the first place, the properly discontinuous groups of motions in a plane will be investigated.

Discontinuous groups of motions.

Any set of finite displacements in a plane generate, by their combination and repetition, a group of motions; but such a group will in general be improperly discontinuous. If the group leaves one point unchanged it must consist of rotations round this point; and it will be either a group of finite order or improperly discontinuous. If it leaves no point unaltered it must contain operations arising from equal and opposite rotations about different points, *i.e.*, it must contain translations. A properly discontinuous group of motions in the plane whose order is not finite must therefore contain translations. If the axis of x be taken parallel to the direction of a translation, and if a be the magnitude of the smallest translation in the group, parallel to the axis of x, then

$$x' = x + ma,\ y' = y,$$

or

$$z' = z + ma,$$

where

$$z = x + iy,$$

represents the cyclical subgroup generated by the translation a.

Suppose first that the group contains no other translations than these. If it contain rotations, the origin may be chosen so as to be the fixed point of a rotation. If α is the angle, the rotation is represented by

$$x' = x\cos\alpha - y\sin\alpha,\ y' = x\sin\alpha + y\cos\alpha,$$

or

$$z' = e^{i\alpha}z.$$

If the translation be represented by T and the rotation by R, then $R^{-1}TR$ is

$$z = z + ae^{i\alpha},$$

a translation in a direction inclined at an angle α to the axis of a. Hence α must be π, and the rotation must be through two right angles. A second rotation R′, with h, k for a fixed point, contained in the group, is represented by

$$z' - h - ik = -(z - h - ik)\ ;$$

and RR′ is

$$z' = z + 2(h + ik).$$

Hence k must be zero, and $2h$ a multiple of a, or

$$R' = T^{-n}RT^n$$

where n is some integer.

It follows that when there is a single set of translations the group must be either

(i.) . . . $z' = z + ma$,

or

(ii.) . . . $z' = \pm z + ma$.

Suppose next that the group contains translations in more than one direction. It may then be assumed without loss of generality that the subgroup formed of its translations, since it is properly discontinuous, is generated by

$$z' = z + a,\ z' = z + be^{i\beta}.$$

If

$$z' = z + ce^{i\gamma}$$

is any other translation of the group, it must be possible to find integers m and n such that

$$ce^{i\gamma} = ma + nbe^{i\beta}.$$

Let R be a rotation of the group whose angle is α, and whose fixed point may be taken to be the origin. Then if T is the general translation $R^{-p}TR^{p}$, or

$$z' = z + mae^{ip\alpha} + nbe^{i(p\alpha+\beta)}$$

is a translation belonging to the group. Hence, whatever integers m and n and p may be, it must be possible to find two integers m' and n', such that

$$m'a + n'be^{i\beta} = mae^{ip\alpha} + nbe^{i(p\alpha+\beta)}.$$

A discussion of this relation will show that if a and b are unequal α must be π. If, however, a and b are equal, the further values $\beta = \frac{\pi}{2}$, $\alpha = \frac{\pi}{2}$; $\beta = \frac{2\pi}{3}$, $\alpha = \frac{2\pi}{3}$; $\beta = \frac{2\pi}{3}$, $\alpha = \frac{\pi}{3}$, are admissible. It may be shown, as in the former case, that if R′ is another rotation of the group, then R′ is the result of transforming R (or one of its powers) by a suitable translation. The remaining types of properly discontinuous groups of motions in the plane may now be written down. They are

(iii.) . . $z' = z + ma + nbe^{i\beta}$,

(iv.) . . $z' = \pm z + ma + nbe^{i\beta}$,

(v.) . . $z' = e^{\frac{ip\pi}{2}} z + (m + in)a$,

(vi.) . . $z' = e^{\frac{2ip\pi}{3}} z + \left(m + ne^{\frac{2i\pi}{3}}\right)a$,

(vii.) . . $z = e^{\frac{ip\pi}{3}} z + \left(m + ne^{\frac{2i\pi}{3}}\right)a$,

where m, n, p, are any integers.

In connexion with each of these groups the whole plane may be divided into congruent portions which are interchanged among themselves by the operations of the group. In the simpler cases this is obvious. For instance, for the group (iii.) the parallelograms into which the plane is divided by the lines

$$y = mb \sin \beta,$$
$$x \sin \beta - y \cos \beta = na \sin \beta,$$

m and n taking all integral values, are clearly such a set of regions. In general such regions may be constructed as follows:—Let P be any point in the plane and P′, P″,... the points to which the various operations of the group displace P. With P, P′, P″,... as centres, suppose circles to be described with the same radius, this being taken at first so small that no two circles meet. Let the radii increase at the same rate, continuing to do so till the circles begin to meet. Wherever the circles meet let the radii cease increasing. In this way a region will be formed round each of the points P, P′, P″,... bounded by straight lines. From their mode of formation these regions are necessarily all congruent; and the operations of the group, which interchange the points P, P′, P″,... among themselves, also interchange the regions. The regions thus constructed are susceptible of an infinite variety of form owing to the arbitrary position of P. No two points in any one region can be displaced, the one into the other, by an operation of the group; and corresponding to any given point within one region there is just one point within any other region to which it may be brought by an operation of the group. Any one region with these properties is called a *fundamental* region for the group; and the same phrase is used in connexion with discontinuous groups of plane and space transformations other than groups of motions. For an improperly discontinuous group no region of finite size exists with the properties of a fundamental region.

Discontinuous groups arising from inversions.

As a second class of examples certain groups of the plane will be considered which arise from the plane transformation known as inversion. Let $A_1A_2\ldots A_n$ be a polygon whose sides are circular arcs, and suppose that each of the internal angles of the polygon is either a submultiple of two right angles or zero. If this polygon be inverted at one of its sides A_1A_2, a new polygon is formed with the same properties as the original, and having the side A_1A_2 only in common with it. The result of inverting at any one of the sides of the new polygon is equivalent to that of successive inversions at three (properly chosen) sides of the original polygon. Suppose now that new polygons are continually formed by inverting those already constructed at their sides. From the mode of formation, no two polygons thus constructed can have any area in common unless they coincide entirely. The original polygon is therefore a fundamental region for the group generated by inversions at its sides; and this group is therefore a properly discontinuous group. Let the polygons be divided into two sets such that the fundamental polygon and all that are derived from it by an even number of inversions form the first set, while those derived from the fundamental polygon by an odd number of inversions form the second. Then both the first set and the second set of polygons are changed into itself by any operation of the group which is given by an even number of inversions. The totality of the operations which arise from an even number of inversions at the sides of the fundamental polygon therefore constitutes a discontinuous group G for which the region formed by the original polygon and its inverse at A_1A_2 is a fundamental region. If

$$R_1, R_2, \ldots, R_n$$

represent inversions at the sides

$$A_1A_2, A_2A_3, \ldots, A_nA_1$$

of the original polygon, the group G can be generated by the operations

$$R_nR_1, R_1R_2, \ldots, R_{n-2}R_{n-1},$$

or

$$S_1, S_2, \ldots, S_{n-1};$$

since from these any operation consisting of an even number of inversions can clearly be constructed. Now an inversion at a circle whose centre is (a_1, b_1) and radius c_1 is given analytically by the equations

$$\frac{x'-a_1}{x-a_1} = \frac{y'-b_1}{y-b_1} = \frac{c_1^2}{(x-a_1)^2+(y-b_1)^2}.$$

If

$$x + iy = z, \; a_1 + ib_1 = \alpha_1,$$
$$x - iy = \bar{z}, \; a_1 - ib_1 = \bar{\alpha}_1,$$

these are equivalent to the single equation

$$z' - \alpha_1 = \frac{c_1^2}{\bar{z} - \bar{\alpha}_1};$$

and similarly an inversion at a second circle is given by

$$z' - \alpha_2 = \frac{c_2^2}{\bar{z} - \bar{\alpha}_2}.$$

Hence the plane transformation that arises from the two inversions performed successively is

$$z' = \alpha_2 + \frac{c_2^2}{\bar{\alpha}_1 - \bar{\alpha}_2 + \dfrac{c_1^2}{z - \alpha_1}}$$

or

$$z' = \frac{\alpha z + \beta}{\gamma z + \delta}$$

where α, β, γ, δ are constants (in general complex) depending on the two circles. The generating operations $S_r (r = 1, 2, \ldots, n-1)$ of the group G are therefore $n-1$ fractional linear substitutions

$$z' = \frac{\alpha_r z + \beta_r}{\gamma_r z + \delta_r},\ (r = 1, 2, \ldots, n-1)$$

performed on the variable z; and since any two linear substitutions performed successively lead to another linear substitution, every operation of the group will be represented by a linear substitution. The linear substitution that results from successive inversions at two circles which intersect at an angle π/m, where m is an integer, is an operation of finite order m. Hence if

$$\frac{\pi}{m_1}, \frac{\pi}{m_2}, \ldots, \frac{\pi}{m_{n-1}}$$

are the internal angles of the original polygon at $A_1, A_2, \ldots, A_{n-1}$, the generating operations of the group are subject to the relations

$$S_1^{m_1} = 1,\ S_2^{m_2} = 1, \ldots, S_{n-1}^{m_{n-1}} = 1.$$

The operation consisting of successive inversions at A_nA_1 and $A_{n-1}A_n$ is represented in terms of the generating operations by $S_1S_2\ldots S_{n-1}$. Hence, if π/m_n is the internal angle of the polygon at A_n,

$$(S_1S_2\ldots S_{n-1})^{m_n} = 1.$$

If the fundamental polygon be taken to correspond to the identical operation, then each polygon in the figure will correspond to that operation of the group which transforms the fundamental polygon into it. The polygon which corresponds to any operation $S_a^\alpha S_b^\beta\ldots$ of the group may be found by drawing a line from the fundamental polygon to the polygon S_a^α; continuing it from the polygon S_a^α to that into which S_b^β transforms it, and so on. To any further relation between the generating operations, such as

$$S_a^\alpha S_b^\beta \ldots S_a^\delta = 1,$$

will correspond a closed path returning to the fundamental polygon. But any such closed path may be continuously deformed, without crossing any of the angular points, into a series of loops surrounding the angular points; and, therefore, any such relation is a consequence of the relations giving the periods of the generating operations and of their product $S_1S_2\ldots S_{n-1}$. The n relations

$$S_1^{m_1} = 1,\ S_2^{m_2} = 1, \ldots, S_{n-1}^{m_{n-1}} = 1,\ (S_1S_2\ldots S_{n-1})^{m_n} = 1,$$

therefore completely define the group. If one or more of the internal angles of the polygon are zero, the number of the relations will be diminished. In the extreme case when all the angles are zero the figure will represent graphically a perfectly general discontinuous group generated by $n-1$ operations which are subject to no relations.

As a particular example, the analytical form of the group will be calculated when the polygon is a triangle whose angles are 0, $\pi/2$, and $\pi/3$. The sides A_3A_1, A_1A_2, A_2A_3 of such a triangle may be taken to be

$$2x + 1 = 0,\ x = 0,\ x^2 + y^2 - 1 = 0$$

respectively. The operations R_1, R_2, R_3 are then

$$z' = -\bar{z},\ z' = \frac{1}{\bar{z}},\ z' = -1 - \bar{z};$$

and the operations S_1, S_2 are

$$z' = z + 1,\ z' = \frac{-1}{z}.$$

Moreover, the group is abstractly defined by the relations

$$S_2^2 = 1,\ (S_1S_2)^3 = 1.$$

It has been already seen that the operations S_1 and S_2 generate the discontinuous group constituted of all substitutions of the form

$$z' = \frac{az + b}{cz + d},$$

where a, b, c, d are integers for which

$$ad - bc = 1.$$

The geometrical origin now obtained for this group makes it clear that, when z is regarded as a complex variable, the group is properly discontinuous, and that the necessary and sufficient defining relations of the group are those previously stated. The class of properly discontinuous groups of linear substitutions here considered is only one from an infinite variety of such classes; and it has been chosen rather for the extreme simplicity of its geometrical form than for any other reason. For a more complete discussion the reader is referred to the memoirs of Poincaré and Klein mentioned later.

Returning now for a time to the discontinuous groups of motions in the plane, it is to be noticed that each one underlies and, in fact, is fundamental in the theory of a corresponding set of functions. In regard to any group of transformations of a single variable, the question may be asked, "What function of the variable is invariant for all the transformations of the group?" If the group is continuous or improperly discontinuous the only invariant uniform function is a constant. But if the group is properly discontinuous, invariant uniform functions other than constants will always exist. Thus for the group

$$z' = z + ma$$

any simply periodic function of period a is invariant, and for the group

$$z' = z + ma + nbe^{i\beta}$$

any doubly periodic function with a and $be^{i\beta}$ for its periods is invariant. In a similar way, to every properly discontinuous group of fractional linear substitutions there corresponds a class of uniform functions which are invariant for all substitutions of the group. These are the so-called automorphic functions. For the particular group generated by

$$z' = z + 1,\ z' = -\frac{1}{z}$$

the simplest automorphic function is the absolute invariant of a non-singular cubic curve for which z represents the ratio of the periods of the associated elliptic functions; and this group is therefore fundamental in the theory of the modular functions.

For space of three dimensions the theories, analogous to those that have been described for the plane, are, as is to be expected, more complicated. The investigation of the properly discontinuous groups of motions in space has been carried out completely, and forms the mathematical basis for the theory of crystallography. The result arrived at is that there are 65 distinct types of such groups. In their analytical form these groups must be represented as linear transformations of a set of three real variables; and they cannot, except in the cases already dealt with, be represented as transformations of one or of two variables. No detailed account of discontinuous groups of space transformations which arise from inversions can be entered on here, but their importance may be made clear by a simple illustration. The discontinuous group that arises from inversions at a given set of circles in a plane is simply isomorphic with that which arises from inversions at the spheres which have their centres in the plane and pass through the given circles. Now the group of space transformations arising from the spheres may be properly discontinuous though the group of plane transformations is not. For instance, if the circles in the plane are the three sides of an equilateral triangle and the circumscribing circle, the group of plane transformations is improperly

discontinuous. The corresponding spheres (three of them being in this case planes) meet in a spherical tetrahedron all of whose dihedral angles are $\pi/3$; and the group of space transformations is therefore properly discontinuous.

The special classes of discontinuous groups that have been so far dealt with arise directly from geometrical considerations. As a final example we shall refer briefly to a class of groups whose origin is essentially analytical. Let

Group of a linear differential equation.

$$\frac{d^ny}{dx^n}+\mathrm{P}_1\frac{d^{n-1}y}{dx^{n-1}}+\ldots+\mathrm{P}_{n-1}\frac{dy}{dx}+\mathrm{P}_ny=0$$

be a linear differential equation, the coefficients in which are rational functions of x, and let $y_1, y_2, \ldots, y_n$ be a linearly independent set of integrals of the equation. In the neighbourhood of a finite value x_0 of x, which is not a singularity of any of the coefficients in the equation, these integrals are ordinary power-series in $x-x_0$. If the analytical continuations of $y_1, y_2, \ldots, y_n$ be formed for any closed path starting from and returning to x_0, the final values arrived at when x_0 is again reached will be another set of linearly independent integrals. When the closed path contains no singular point of the coefficients of the differential equation, the new set of integrals is identical with the original set. If, however, the closed path encloses one or more singular points, this will not in general be the case. Let $y'_1, y'_2, \ldots, y'_n$ be the new integrals arrived at. Since in the neighbourhood of x_0 every integral can be represented linearly in terms of $y_1, y_2 \ldots, y_n$, there must be a system of equations

$$\begin{aligned}y'_1&=a_{11}y_1+a_{12}y_2+\ldots+a_{1n}y_n,\\ y'_2&=a_{21}y_1+a_{22}y_2+\ldots+a_{2n}y_n,\\ &\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\\ y'_n&=a_{n1}y_1+a_{n2}y_2+\ldots+a_{nn}y_n,\end{aligned}$$

where the a's are constants, expressing the new integrals in terms of the original ones. To each closed path described by x_0 there therefore corresponds a definite linear substitution performed on the y's. Further, if S_1 and S_2 are the substitutions that correspond to two closed paths L_1 and L_2, then to any closed path which can be continuously deformed, without crossing a singular point, into L_1 followed by L_2, there corresponds the substitution $\mathrm{S}_1\mathrm{S}_2$. Let $\mathrm{L}_1, \mathrm{L}_2, \ldots, \mathrm{L}_r$ be arbitrarily chosen closed paths starting from and returning to the same point, and each of them enclosing a single one of the (r) finite singular points of the equation. Every closed path in the plane can be formed by combinations of these r paths taken either in the positive or in the negative direction. Also a closed path which does not cut itself, and encloses all the r singular points within it, is equivalent to a path enclosing the point at infinity and no finite singular point. If $\mathrm{S}_1, \mathrm{S}_2, \mathrm{S}_3 \ldots, \mathrm{S}_r$ are the linear substitutions that correspond to these r paths, then the substitution corresponding to every possible path can be obtained by combination and repetition of these r substitutions, and they therefore generate a discontinuous group each of whose operations corresponds to a definite closed path. The group thus arrived at is called the group of the equation. For a given equation it is unique in type. In fact, the only effect of starting from another set of independent integrals is to transform every operation of the group by an arbitrary substitution, while choosing a different set of paths is equivalent to taking a new set of generating operations. The great importance of the group of the equation in connexion with the nature of its integrals cannot here be dealt with, but it may be pointed out that if all the integrals of the equation are algebraic functions, the group must be a group of finite order, since the set of quantities $y_1, y_2, \ldots, y_n$ can then only take a finite number of distinct values. As a simple example of the determination of the group from the differential equation, we may take the equation

$$x^3\frac{d^3y}{dx^3}+(x-x^2)\frac{dy}{dx}-y=0.$$

There is only one finite singular point, namely $x=0$, and therefore the group is cyclical. The determinantal equation at $x=0$ is

$$(n-1)^3=0,$$

and the form of the three independent integrals must therefore be

$$u,\ v+u\log x,\ w+2v\log x+u(\log x)^2,$$

where u, v, w are power-series of which u vanishes with x. If these are represented by y_1, y_2, y_3, the substitution given by a closed path surrounding $x=0$ is

$$y'_1=y_1,\ y'_2=y_2+2\pi iy_1,\ y'_3=y_3+4\pi iy_2-4\pi^2y_1,$$

and the group of the equation is the cyclical group generated by this substitution.

Groups of Finite Order.

We shall now pass on to the last division of the subject, that is, to groups of finite order. It is clear that here we must have to do with many properties which have no direct analogues in the theory of continuous groups or in that of discontinuous groups in general; those properties, namely, which depend on the fact that the number of distinct operations in the group is finite.

Let

$$\mathrm{S}_1, \mathrm{S}_2, \mathrm{S}_3, \ldots, \mathrm{S}_N,$$

denote the operations of a group G of finite order N, S_1 being the identical operation. The tableau

$$\begin{array}{llll}\mathrm{S}_1, & \mathrm{S}_2, & \mathrm{S}_3, \ldots, & \mathrm{S}_N,\\ \mathrm{S}_1\mathrm{S}_2, & \mathrm{S}_2\mathrm{S}_2, & \mathrm{S}_3\mathrm{S}_2, \ldots, & \mathrm{S}_N\mathrm{S}_2,\\ \mathrm{S}_1\mathrm{S}_3, & \mathrm{S}_2\mathrm{S}_3, & \mathrm{S}_3\mathrm{S}_3, \ldots, & \mathrm{S}_N\mathrm{S}_3,\\ \cdot & \cdot & \cdot & \cdot\\ \mathrm{S}_1\mathrm{S}_N, & \mathrm{S}_2\mathrm{S}_N, & \mathrm{S}_3\mathrm{S}_N, \ldots, & \mathrm{S}_N\mathrm{S}_N,\end{array}$$

when in it each compound symbol $\mathrm{S}_p\mathrm{S}_q$ is replaced by the single symbol S_r that is equivalent to it, is called the multiplication table of the group. It indicates directly the result of multiplying together in an assigned sequence any number of operations of the group. In each line (and in each column) of the tableau every operation of the group occurs just once. If the letters in the tableau are regarded as mere symbols, the operation of replacing each symbol in the first line by the symbol which stands under it in the pth line is a substitution performed on the set of N symbols. Thus to the N lines of the tableau there corresponds a set of N substitutions performed on the N symbols, which includes the identical substitution that leaves each unchanged. Moreover, if $\mathrm{S}_p\mathrm{S}_q=\mathrm{S}_r$, then the result of carrying out in succession the substitutions which correspond to the pth and qth lines gives the substitution which corresponds to the rth line. Hence the set of substitutions constitutes a group which is simply isomorphic with the given group.

Every group of finite order N can therefore be represented in concrete form as a group of substitutions on N symbols.

The order of any subgroup or operation of G is necessarily finite. If

$$\mathrm{T}_1(=\mathrm{S}_1),\ \mathrm{T}_2, \ldots, \mathrm{T}_n,$$

Properties of a group which depend on the order.

are the operations of a subgroup H of G, and if Σ is any operation of G which is not contained in H, the set of operations

$$\Sigma\mathrm{T}_1, \Sigma\mathrm{T}_2, \ldots, \Sigma\mathrm{T}_n,$$

or ΣH, are all distinct from each other and from the

operations of H. If the sets H and Σ'H do not exhaust the operations of G, and if Σ' is an operation not belonging to them, then the operations of the set ΣH are distinct from each other and from those of H and ΣH. This process may be continued till the operations of G are exhausted. The order n of H must therefore be a factor of the order N of G. The ratio N/n is called the *index* of the subgroup H. By taking for H the cyclical subgroup generated by any operation S of G, it follows that the order of S must be a factor of the order of G.

Every operation S is permutable with its own powers. Hence there must be some subgroup H of G of greatest possible order, such that every operation of H is permutable with S. Every operation of H transforms S into itself, and every operation of the set HΣ transforms S into the same operation. Hence, when S is transformed by every operation of G, just N/n distinct operations arise if n is the order of H. These operations, and no others, are conjugate to S within G; they are said to form a set of conjugate operations. The number of operations in every conjugate set is therefore a factor of the order of G. In the same way it may be shown that the number of subgroups which are conjugate to a given subgroup is a factor of the order of G. An operation which is permutable with every operation of the group is called a *self-conjugate* operation. The totality of the self-conjugate operations of a group forms a self-conjugate Abelian subgroup, each of whose operations is permutable with every operation of the group.

An Abelian group contains subgroups whose orders are any given factors of the order of the group. In fact, since every subgroup H of an Abelian group G and the corresponding factor groups G/H are Abelian, this result follows immediately by an induction from the case in which the order contains n prime factors to that in which it contains $n+1$. For a group which is not Abelian no general law can be stated as to the existence or non-existence of a subgroup whose order is an arbitrarily assigned factor of the order of the group. In this connexion the most important general result, which is independent of any supposition as to the nature of the group, is known as Sylow's theorem, which states that if p^{α} is the highest power of a prime p which divides the order of a group G, then G contains a single conjugate set of subgroups of order p^{α}, the number in the set being of the form $1+kp$. This theorem, which is of fundamental importance, may be established as follows:—

Let r be the number of distinct sets of conjugate operations in G, and let

Sylow's theorem.

$$h_1(=1),\ h_2,\ h_3,\ldots,\ h_r,$$

be the numbers of operations in each set, the first set consisting of the identical operation alone. Any operation of the sth set is contained as a self-conjugate operation in a subgroup of order n_s, where $n_s h_s = \mathrm{N}$, the order of the group.

The order of the group being equal to the sum of the numbers of operations in the different conjugate sets, it follows that

$$\mathrm{N}=1+\frac{\mathrm{N}}{n_2}+\frac{\mathrm{N}}{n_3}+\ldots+\frac{\mathrm{N}}{n_r}.$$

If G contains no self-conjugate operation except the identical operation, no one of the denominators on the right-hand side is N, and at least one of them must be divisible by p^{α}. In this case, then, G contains a subgroup whose order is divisible by p^{α}. If G has self-conjugate operations, the same result is arrived at by considering the factor group G/H, where H is the subgroup constituted of the totality of the self-conjugate operations; and G, therefore, in any case contains a subgroup whose order is divisible by p^{α}. The same reasoning may be repeated with this subgroup, and so ultimately a subgroup of order p^{α} must be arrived at. The existence within G of a subgroup P of order p^{α} is thus demonstrated. If this subgroup is not self-conjugate, let P$'$ be another subgroup of order p^{α} conjugate to it. When P$'$ is transformed by all the operations of P, the number of distinct groups, including P$'$, which arise is $p^{\alpha-\beta}$, where p^{β} is the order of the greatest group common to P and P$'$. If the $1+p^{\alpha-\beta}$ groups so obtained do not exhaust all the subgroups conjugate to P in G, let P$''$ be a new one. On transforming P$''$ by the operations of P, $p^{\alpha-\beta'}$ new groups arise, which are distinct from each other and from the previous $1+p^{\alpha-\beta}$. This process may be continued till the groups conjugate to P are exhausted. Their number is therefore of the form $1+kp$. The supposition that G contains a second conjugate set of subgroups of order p^{α} leads by a similar process to the obvious contradiction that the number of subgroups in the set is at once of the forms $1+kp$ and lp. The theorem is therefore completely proved. Sylow's theorem may be extended to show that if $p^{\alpha'}$ is a factor of the order of a group, the number of subgroups of order $p^{\alpha'}$ is of the form $1+kp$. If, however, $p^{\alpha'}$ is not the highest power of p which divides the order, these groups do not in general form a single conjugate set.

The importance of Sylow's theorem in discussing the structure of a group of given order need hardly be insisted on. Thus, as a very simple instance, a group whose order is the product p_1p_2 of two primes ($p_1<p_2$) must have a self-conjugate subgroup of order p_2, since the order of the group contains no factor, other than unity, of the form $1+kp_2$. The same again is true for a group of order $p_1^2p_2$, unless $p_1=2$, and $p_2=3$.

There is one other numerical property of a group connected with its order which is quite general. If N is the order of G, and n a factor of N, the number of operations of G, whose orders are equal to or are factors of n, is a multiple of n.

Composition-series of a group.

As already defined, a composite group is a group which contains one or more self-conjugate subgroups, whose orders are greater than unity. If H is a self-conjugate subgroup of G, the factor-group G/H may be either simple or composite. In the former case G can contain no self-conjugate subgroup K, which itself contains H; for if it did K/H would be a self-conjugate subgroup of G/H. When G/H is simple, H is said to be a maximum self-conjugate subgroup of G. Suppose now that G being a given composite group,

$$\mathrm{G},\ \mathrm{G}_1,\ \mathrm{G}_2,\ldots,\ \mathrm{G}_n,\ 1,$$

is a series of subgroups of G, such that each is a maximum self-conjugate subgroup of the preceding; the last term of the series consisting of the identical operation only. Such a series is called a *composition-series* of G. In general it is not unique, since a group may have two or more maximum self-conjugate subgroups. A composition-series of a group, however it may be chosen, has the property that the number of terms of which it consists is always the same, while the factor-groups

$$\mathrm{G}/\mathrm{G}_1,\ \mathrm{G}_1/\mathrm{G}_2,\ldots,\ \mathrm{G}_n,$$

differ only in the sequence in which they occur. Let G_1 and G'_1 be two maximum self-conjugate subgroups of G, and let H be the common subgroup of G_1 and G'_1. The group $\{\mathrm{G}_1, \mathrm{G}'_1\}$ generated by G_1 and G'_1 is contained self-conjugately in G, and must therefore coincide with G, since G_1 and G'_1 are maximum self-conjugate subgroups. Also H, being the common subgroup of two self-conjugate subgroups of G, is a self-conjugate subgroup of G,

G_1, and G'_1. Now the factor-group $\{G_1, G'_1\}/G_1$ is identical with $\{g_1, g'_1\}/g_1$, where g_1 and g'_1 represent G_1/H and G'_1/H. But $\{g_1, g'_1\}/g_1$ is identical with g'_1, since g_1 and g'_1 have no common operations. Hence G/G_1 is identical with G'_1/H; and similarly G/G'_1 is identical with G_1/H. Moreover, H is a maximum self-conjugate subgroup of both G_1 and G'_1. Suppose now that

$$G, G_1, G_2, \ldots, 1,$$

and

$$G, G'_1, G'_2, \ldots, 1,$$

are two composition-series of G. Since H is a maximum self-conjugate subgroup of both G_1 and G'_1, there must be two other composition-series of the form

$$G, G_1, H, I, J, \ldots, 1,$$

and

$$G, G'_1, H, I, J, \ldots, 1;$$

and for these the factor-groups are identical except as regards sequence.

The property stated of the composition-series may now be proved by an induction. Suppose it to have been established for all groups whose order does not exceed n, and let the order of G be not greater than $2n$, so that the orders of G_1 and G'_1 do not exceed n. Then the series

$$G_1, G_2, \ldots, 1,$$
$$G_1, H, \ldots, 1,$$

have the same number of terms, and apart from sequence the same factor-groups; as also have the series

$$G'_1, G'_2, \ldots, 1,$$
$$G'_1, H, \ldots, 1.$$

Hence the same is true for the series

$$G, G_1, G_2, \ldots, 1,$$
$$G, G'_1, G'_2, \ldots, 1.$$

For a group of sufficiently small order the property is obviously true, and it is thus established generally. It should be noticed that though a group defines uniquely the set of factor-groups that occur in its composition-series, the set of factor-groups do not conversely in general define a single type of group. When the orders of all the factor-groups are primes the group is said to be *soluble*.

If the series of subgroups

$$G, H, K, \ldots, L, 1$$

is chosen so that each is the greatest self-conjugate subgroup of G contained in the previous one, the series is called a chief composition-series of G. All such series derived from a given group may be shown to consist of the same number of terms, and to give rise to the same set of factor-groups, except as regards sequence. The factor-groups of such a series will not, however, necessarily be simple groups. From any chief composition-series a composition-series may be formed by interpolating between any two terms H and K of the series for which H/K is not a simple group, a number of terms $h_1, h_2, \ldots, h_r$; and it may be shown that the factor-groups $H/h_1, h_1/h_2, \ldots, h_r/K$ are all simply isomorphic with each other.

Isomorphism of a group with itself.

A group may be represented as isomorphic with itself by transforming all its operations by any one of them. In fact, if

$$S_pS_q = S_r,$$

then

$$S^{-1}S_pS \cdot S^{-1}S_qS = S^{-1}S_rS.$$

An isomorphism of the group with itself, established in this way, is called a *cogredient* isomorphism. It may be regarded as an operation carried out on the symbols of the operations, being indeed a substitution performed on these symbols. The totality of these operations clearly constitutes a group isomorphic with the given group, and this group is called the group of cogredient isomorphisms. A group is simply or multiply isomorphic with its group of cogredient isomorphisms according as it does not or does contain self-conjugate operations other than identity. It may be possible to establish a correspondence between the operations of a group other than those given by the cogredient isomorphisms, such that if S' is the operation corresponding to S, then

$$S'_pS'_q = S'_r$$

is a consequence of

$$S_pS_q = S_r.$$

The substitution on the symbols of the operations of a group resulting from such a correspondence is called a *contragredient* isomorphism. The totality of the isomorphisms of both kinds constitutes the group of isomorphisms of the given group, and within this the group of cogredient isomorphisms is a self-conjugate subgroup. Every set of conjugate operations of a group is necessarily transformed into itself by a cogredient isomorphism, but two or more sets may be interchanged by a contragredient isomorphism.

A group which has no self-conjugate operations except identity, and admits of no contragredient isomorphisms, is called a *complete* group. If a group G has a complete group H as a self-conjugate subgroup, then G contains a subgroup K simply isomorphic with G/H, such that every operation of K is permutable with every operation of H; and G is said to be the *direct product* of H and K.

A subgroup of a group G, which is transformed into itself by every isomorphism of G, is called a characteristic subgroup. A series of groups

$$G, G_1, G_2, \ldots, 1,$$

such that each is a maximum characteristic subgroup of G contained in the preceding, may be shown to have the same invariant properties as the subgroups of a composition series. A group which has no characteristic subgroup must be either a simple group or the direct product of a number of simply isomorphic simple groups.

Simple and composite groups. Soluble groups.

It is an obvious result from Sylow's theorem that, when a given number is assigned arbitrarily as the order of a group, there is not in general among the possible types of group a simple group. The examination of successive integers, from this point of view, has been carried as far as 1092, with the result of showing that 60, 168, 360, 504, 660, and 1092 are the only orders not exceeding 1092 corresponding to which simple groups exist, and that for each of these numbers as order there is a single type of simple group. On the other hand, the number of simple groups known to exist is infinite and is being continually added to. Thus for every order of the forms

$$\tfrac{1}{2}n\,!,\ \tfrac{1}{2}(p^{2n}-1)p^n \text{ and } \frac{1}{d}p^{\frac{n(n-1)}{2}}(p^n-1)(p^{n-1}-1)\ldots(p-1),$$

where n is any integer, p a prime, and d the highest common factor of n and $p-1$, a simple group is known to exist; and the same may be stated of several other forms for the order. Again, a series of forms for the order of a group are known corresponding to which there can be no simple group, and these also tend to increase with new investigations. Thus if $p, q, r, \ldots$ denote primes, groups of order p^n, p^nq, p^nq^2 and $pq\ldots r$ are always soluble; and a group of order $p^\alpha q^\beta \ldots r^\gamma$, where none of the indices exceed two, is always soluble unless twelve is a factor of the order. If the number of prime factors in the order of a group does not exceed five, the group is composite unless 60, 168, 660, or 1092 is the order. If the order of a group is twice an odd number, the group is always composite, containing a self-conjugate subgroup of index two. Finally, no simple group of odd order is at present known to exist.

It has been seen that every group of finite order can be represented as a group of substitutions performed on a set of symbols whose number is equal to the order of the group. In general such a representation is possible with a smaller number of symbols. Let H be a subgroup of G, and let the operations of G be divided, in respect of H, into the sets

Substitution-groups.

$$H, S_2H, S_3H, \ldots, S_mH.$$

If S is any operation of G, the sets

$$SH, SS_2H, SS_3H, \ldots, SS_mH,$$

differ from the previous sets only in the sequence in which they occur. In fact, if SS_p belong to the set S_qH, then since H is a group, the set SS_pH is identical with the set S_qH. Hence, to each operation S of the group will correspond a substitution performed on the symbols of the m sets, and to the product of two operations corresponds the product of the two analogous substitutions. The set of substitutions, therefore, forms a group isomorphic with the given group. Moreover, the isomorphism is simple unless for one or more operations, other than identity, the sets all remain unaltered. This can only be the case for S, when every operation conjugate to S belongs to H. In this case H would contain a self-conjugate subgroup. Hence, if H is a subgroup of G of index m, which contains no self-conjugate subgroup of G, then G can be represented as a group of substitutions performed on m symbols.

The fact that every group of finite order can be represented, generally in several ways, as a group of substitutions, gives special importance to such groups. The number of symbols involved in such a representation is called the *degree* of the group. In accordance with the general definitions already given, a substitution-group is called transitive or intransitive according as it does or does not contain substitutions changing any one of the symbols into any other. It is called imprimitive or primitive according as the symbols can or cannot be arranged in sets, such that every substitution of the group changes the symbols of any one set either among themselves or into the symbols of another set. When a group is imprimitive the number of symbols in each set must clearly be the same.

The total number of substitutions that can be performed on n symbols is $n\,!$, and these necessarily constitute a group. It is known as the *symmetric* group of degree n, the only rational functions of the symbols which are unaltered by all possible substitutions being the symmetric functions. When any substitution is carried out on the product of the $n(n-1)/2$, differences of the n symbols, it must either remain unaltered or its sign must be changed. Those substitutions which leave the product unaltered constitute a group of order $n\,!/2$, which is called the *alternating* group of degree n; it is a self-conjugate subgroup of the symmetric group. Except when $n=4$ the alternating group is a simple group; and except for $n=6$ the symmetric group is a complete group. A substitution group of degree n, which is not contained in the alternating group, must necessarily have a self-conjugate subgroup of index 2, consisting of those of its substitutions which belong to the alternating group. The determination of all possible subgroups of the symmetric group has been carried out for some of the smaller values of n. Of greater interest and importance is the determination of the transitive and in particular of the primitive subgroups. The latter determination has been made for all values of n up to 15.

Another form in which every group of finite order can be represented is that known as a linear homogeneous group. If in the equations

Linear homogeneous groups

$$x'_r = a_{r1}x_1 + a_{r2}x_2 + \ldots + a_{rm}x_m,$$
$$(r=1, 2, \ldots, m),$$

which define a linear homogeneous substitution, the coefficients are integers, and if the equations are replaced by congruences to a finite modulus n, the system of congruences will give a definite operation, provided that the determinant of the coefficients is relatively prime to n. The product of two such operations is another operation of the same kind; and the total number of distinct operations is finite, since there is only a limited number of choices for the coefficients. The totality of these operations, therefore, constitutes a group of finite order; and such a group is known as a *linear homogeneous* group. If n is a prime the order of the group is

$$(n^m-1)(n^m-n)\ldots(n^m-n^{m-1}).$$

The totality of the operations of the linear homogeneous group for which the determinant of the coefficients is congruent to unity forms a subgroup. Other subgroups arise by considering those operations which leave a function of the variables unchanged (mod. n). All such subgroups are known as linear homogeneous groups.

When the ratios only of the variables are considered, there arises a *linear fractional* group, with which the corresponding linear homogeneous group is isomorphic. Thus, if p is a prime the totality of the congruences

$$\left.\begin{array}{l} z' \equiv \dfrac{az+b}{cz+d}, \\ ad-bc \neq 0, \end{array}\right\} \text{(mod. } p)$$

constitutes a group of order $p(p^2-1)$. This class of groups for various values of p is almost the only one which has been as yet exhaustively analysed. For all values of p except 3 it contains a simple self-conjugate subgroup of index 2.

The operations of a substitution-group, as defined above, are linear substitutions of a very special type, where each symbol is replaced by another single symbol. The difference of any two symbols is also replaced by the difference of some other two. Now every difference of a pair of the symbols

Groups of linear substitutions.

$$x_1, x_2, \ldots, x_n$$

can be expressed linearly in terms of

$$x_1-x_n, x_2-x_n, \ldots, x_{n-1}-x_n.$$

Hence the substitution-group of degree n can be represented as a group of linear substitutions in the more general sense, performed on a set of $n-1$ symbols. A group of linear substitutions on m symbols is called *irreducible* when it is impossible to form m' ($<m$) linear functions of the symbols which are transformed among themselves by every operation of the group. The representation of a given group as a group of linear substitutions in as small a number of symbols as possible, and the determination whether the group so formed is irreducible or not, constitutes one of the main problems of the theory. A simple group when so represented is necessarily irreducible. On the other hand, no Abelian group, other than a cyclical one, can be represented in irreducible form. The only groups of finite order which can be represented as substitution-groups with a single symbol are clearly the cyclical groups. The determination has been made of all types which can be so represented with two and with three symbols. The difficulties presented by the cases of four symbols are very considerable and have not yet been overcome. That among the latter a group of order 25920 occurs indicates the great number of possibilities.

The chief application of the theory of groups of finite order is to the theory of algebraic equations. The analogy of equations of the second, third, and fourth degrees would give rise to the expectation that a root of an equation of any finite degree

Applications.

could be expressed in terms of the coefficients by a finite number of the operations of addition, subtraction, multiplication, division, and the extraction of roots; in other words, that the equation could be solved by radicals. This, however, as proved by Abel and Galois, is not the case: an equation of a higher degree than the fourth in general defines an algebraic irrationality which cannot be expressed by means of radicals, and the cases in which such an equation can be solved by radicals must be regarded as exceptional. The theory of groups gives the means of determining whether an equation comes under this exceptional case, and of solving the equation when it does. When it does not, the theory provides the means of reducing the problem presented by the equation to a normal form. From this point of view the theory of equations of the fifth degree has been exhaustively treated, and the problems presented by certain equations of the sixth and seventh degrees have actually been reduced to normal form.

Galois showed that, corresponding to every irreducible equation of the nth degree, there exists a transitive substitution-group of degree n, such that every function of the roots which is unaltered by all the substitutions of the group can be expressed rationally in terms of the coefficients, while conversely every function of the roots which is expressible rationally in terms of the coefficients is unaltered by the substitutions of the group. This group is called the group of the equation. In general, if the equation is given arbitrarily, the group will be the symmetric group. The necessary and sufficient conditions that the equation may be soluble by radicals is that its group should be a soluble group. When the coefficients in an equation are rational integers, the determination of its group may be made by a finite number of processes each of which involves only rational arithmetical operations. These processes consist in forming resolvents of the equation corresponding to each distinct type of subgroup of the symmetric group whose degree is that of the equation. Each of the resolvents so formed is then examined to find whether it has rational roots. The group corresponding to any resolvent which has a rational root contains the group of the equation; and the least of the groups so found is the group of the equation. Thus, for an equation of the fifth degree the various transitive subgroups of the symmetric group of degree five have to be considered. These are (i.) the alternating group; (ii.) a soluble group of order 20; (iii.) a group of order 10, self-conjugate in the preceding; (iv.) a cyclical group of order 5, self-conjugate in both the preceding. If x_0, x_1, x_2, x_3, x_4 are the roots of the equation, the corresponding resolvents may be taken to be those which have for roots (i.) the square root of the discriminant; (ii.) the function $(x_0x_1+x_1x_2+x_2x_3+x_3x_4+x_4x_0)(x_0x_2+x_2x_4+x_4x_1+x_1x_3+x_3x_0)$; (iii.) the function $x_0x_1+x_1x_2+x_2x_3+x_3x_4+x_4x_0$; and (iv.) the function $x_0^2x_1+x_1^2x_2+x_2^2x_3+x_3^2x_4+x_4^2x_0$. Since the groups for which (iii.) and (iv.) are invariant are contained in that for which (ii.) is invariant, and since these are the only soluble groups of the set, the equation will be soluble by radicals only when the function (ii.) can be expressed rationally in terms of the co-efficients. If

$$(x_0x_1+x_1x_2+x_2x_3+x_3x_4+x_4x_0)(x_0x_2+x_2x_4+x_4x_1+x_1x_3+x_3x_0)$$

is known, then clearly

$$x_0x_1+x_1x_2+x_2x_3+x_3x_4+x_4x_0$$

can be determined by the solution of a quadratic equation. Moreover, the sum and product

$$(x_0+\epsilon x_1+\epsilon^2x_2+\epsilon^3x_3+\epsilon^4x_4)^5$$

and

$$(x_0+\epsilon^4x_1+\epsilon^3x_2+\epsilon^2x_3+\epsilon x_4)^5$$

can be expressed rationally in terms of $x_0x_1+x_1x_2+x_2x_3+x_3x_4+x_4x_0$, ϵ, and the symmetric functions; ϵ being a fifth root of unity. Hence $(x_0+\epsilon x_1+\epsilon^2x_2+\epsilon^3x_3+\epsilon^4x_4)^5$ can be determined by the solution of a quadratic equation. The roots of the original equation are then finally determined by the extraction of a fifth root. To show how the problem presented by an equation of the fifth degree, when not soluble by radicals, can be reduced to a normal form, would go far beyond the limits of the present article. This question forms the subject of Prof. Klein's admirable *Vorlesungen über das Ikosaeder*. Another application of groups of finite order is to the theory of linear differential equations whose integrals are algebraic functions. It has been already seen, in the discussion of discontinuous groups in general, that the groups of such equations must be groups of finite order. To every group of finite order which can be represented as an irreducible group of linear substitutions on n variables will correspond a class of irreducible linear differential equations of the nth order whose integrals are algebraic. The complete determination of the class of linear differential equations of the second order with all their integrals algebraic, whose group has the greatest possible order, viz., 120, has been carried out by Prof. Klein.

Grove, Sir George (1820–1900), English writer on music, was born at Clapham, 13th August 1820. At the close of his school days he was articled to a civil engineer, and worked for two years in a factory near Glasgow. In 1841 and 1845 he was employed in the West Indies, erecting lighthouses in Jamaica and Bermuda. In 1849 he became secretary to the Society of Arts, and in 1852 to the Crystal Palace. In this capacity his natural love of music and enthusiasm for the art found a splendid opening, and he threw all the weight of his influence into the task of promoting the best music of all schools in connexion with the weekly and daily concerts at Sydenham, which had such a long and honourable career under the direction of Mr Manns. Without Sir George Grove that eminent conductor would hardly have succeeded in doing what he did to encourage young composers and to educate the British public in music. Grove's analyses of the Beethoven symphonies, and the other works presented at the concerts, set the pattern of what such things should be; and it was as a result of these, and of the fact that he was editor of *Macmillan's Magazine* from 1868 to 1883, that the scheme of his famous *Dictionary of Music and Musicians*, published from 1878 to 1889, was conceived and executed. His own articles on Beethoven, Mendelssohn, and Schubert are monuments of a special kind of learning, and the fact that the rest of the book is a little thrown out of balance owing to their gigantic length is hardly to be regretted. Long before this he had contributed to the *Dictionary of the Bible*, and had promoted the foundation of the Palestine Exploration Fund. On a famous journey to Vienna, undertaken in the company of his lifelong friend, Sir Arthur Sullivan, the important discovery of a large number of compositions by Schubert was made, including the music to *Rosamunde*. When the Royal College of Music was founded in 1882 he was appointed its first director, receiving the honour of knighthood. He fulfilled the duties in such a way as to bring the new institution into line with the most useful European conservatoriums. On the completion of the new buildings in 1894 he resigned the directorship, but retained an active interest in the institution to the end of his life. He died at Sydenham, 28th May 1900. (J. A. F. M.)

Grove, Sir William Robert (1811–1896), English judge and man of science, was born on 11th July 1811 at Swansea, in South Wales. After being educated by private tutors, he went up to Brasenose College, Oxford, where he took an ordinary degree in 1832. Three years later he was called to the bar at Lincoln's Inn. His health, however, did not allow him to devote himself strenuously to practice, and he occupied his leisure with scientific studies. About 1839 he constructed the well-known platinum-zinc voltaic cell that bears his name, and with the aid of a number of these exhibited the electric arc light in the London Institution, Finsbury Circus. The result was that in 1840 the managers appointed him to the professorship of experimental philosophy, an office which he held for seven years. His researches dealt very largely with electro-chemistry and with the voltaic cell, of which he invented several varieties. One of these, the Grove gas-battery, is of especial interest both intrinsically and as the forerunner of the secondary batteries now in use for the "storage" of electricity. He discovered that a current is produced by a couple of platinum plates standing in acidulated water and immersed, the one in hydrogen, the other in oxygen; hence a galvanometer connected to the electrodes of an apparatus for the electrolysis of water which has been in operation for a short time indicates the existence of a current passing in the reverse direction to that which has effected the decomposition, and thus there is a return of part of the electrical energy which has been expended. At one of his lectures at the Institution Grove anticipated the electric lighting of to-day by illuminating the theatre with incandescent electric lamps, the filaments being of platinum and the current supplied by a battery of his nitric acid cells. In 1846 he published his famous book on *The Correlation of Physical Forces*, the leading ideas of which he had already put forward in his lectures: its fundamental conception was that each of the forces of nature—light, heat, electricity, &c.—is definitely and equivalently convertible into any other, and that where experiment does not give the full equivalent, it is because the initial force has been dissipated, not lost, by conversion into other unrecognized forces. In the same year he received a Royal medal from the Royal Society for his Bakerian lecture on "Certain phenomena of voltaic ignition and the decomposition of water into its constituent gases." In 1866 he presided over the British Association at its Nottingham meeting, and delivered an address on the continuity of natural phenomena. But while he was thus engaged in scientific research, his legal work was not neglected, and his practice increased so greatly that in 1853 he became a Q.C. One of the best-known cases in which he appeared as an advocate was that of William Palmer, the Rugeley poisoner, whom he defended. In 1871 he was made a judge of the Common Pleas in succession to Sir Robert Collier, and remained on the bench till 1887. He died in London on 1st August 1896. A selection of his scientific papers will be found appended to the sixth edition of *The Correlation of Physical Forces*, published in 1874.

Groznyi, fortress and district town of Russia, North Caucasia, province of Terek, on the Sunzha river, 58 miles north-east of Vladikavkaz, on the railway to Petrovsk. There are naphtha works close by. Population (1897), 15,599.

Grünberg, a town of Prussia, province of Silesia, 34 miles by rail north-west from Glogau on the line to Frankfort-on-the-Oder. It has manufactures of straw hats, leather, and tobacco. There is a technical (textiles) school. Population (1885), 14,395; (1900), 20,987.

Gruyère, a district in the Swiss canton of Freiburg, famous for its cheese. Properly the name belongs to the whole of the upper valley of the Saane above Bulle, but it is often applied only to the Freiburg portion of this region, from Montbovon to Bulle, its capital. This region now forms the Gruyère prefecture of the canton of Freiburg, and contained in 1900, 22,936 inhabitants, mainly Romanist and French-speaking. In 1900 the town of Bulle had 3317 inhabitants, while that of Gruyères (spelt usually with the final "s" to distinguish it from the district) had 1383. A railway is projected from Bulle up the valley, and another from Montbovon to the Lake of Geneva. The county of Gruyère was seized in 1555 by Berne and Freiburg, the creditors of the last count. The Bernese portion of the upper Saane valley (capital, Château d'Oex), known as the "Pays d'en Haut," passed in 1798 to the Canton Léman (called Vaud after 1803). In 1893, 50,000 cwts. of cheese were exported from the Gruyère district (see also DAIRY FARMING).

Guadalajara, a province of Central Spain, with an area of 4869 English square miles, divided into nine

administrative districts and 398 parishes. Its population decreased from 204,984 in 1887 to 199,290 in 1897. Outside agriculture there are no industries of any importance. This province is crossed by the Madrid–Saragossa railway, which has eleven stations and 70 miles of line in the province. There are 175 miles of first-class roads. The province contains 22 productive and 179 unproductive registered mines. The former employ 350 hands. The salt mines have an output of 9382 tons. In 1898 there were 2670 horses, 29,171 mules, 16,643 asses, 8055 cattle, 440,209 sheep, 51,059 goats, 17,330 pigs: 212,500 acres were devoted to wheat; 330,130 acres to other cereals, chiefly oats, rye, barley, maize; 59,000 acres to vines; and 45,000 acres to olives.

Guadalajara, capital of the above province. A few modern buildings have been erected by the local corporations, such as the prison, provincial hospital, foundling hospital, institute for superior education, training schools for teachers of both sexes, and several primary schools. The once famous cloth manufacture has much decayed. New manufactures of soap, woollens, leather, and bricks have been instituted. Population (1897), 11,075.

Guadalajara, a city of Mexico, and capital of the state of Jalisco. Population (1895), 83,934. It is the principal seat of the cotton and wool manufacturing industries of the country. The public buildings—the cathedral, mint, Degollado theatre, and state Capitol—are splendid specimens of Mexican architecture. The Paseo is a beautiful drive on both sides of the Rio San Juan de Dios. There are numerous parks, and a botanical garden; the hospicio or home for the poor is a notable building. The town has tramways, electric lighting, &c.

Guadeloupe, a French colony in the Lesser Antilles, between Montserrat on the north and Dominica on the south. It has an area of 619 square miles, and consists of two islands, Grande Terre (255 square miles) and Basse Terre (364 square miles), separated by the Rivière Salée ("Salt River"), 4 miles long. The year is divided into the rainy season (July to November), the cool season (December to March), and the dry season (April to June). Round Guadeloupe are grouped its dependencies, namely, La Désirade, 6 miles east, with an area of 10 square miles; Marie Galante, 16 miles south-east, with an area of 55 square miles, traversed by the river St Louis; Les Saintes, 7 miles south, one of the strategic points of the Antilles; St Barthélemy, 95 miles north-west, with an area of 8 square miles (retroceded to France by Sweden in 1877); St Martin, 125 miles north-west, belonging to the extent of two-thirds to France, the remainder being Dutch. The population of Guadeloupe and its dependencies in 1887 was 182,000; but in 1898 it had fallen to 167,000, in consequence of the crisis in sugar production. In 1898 the men numbered 50,000, the women 53,500, and children 48,000. The immigrants, chiefly from India, numbered 15,500. The towns in the islands are: Basse Terre, the seat of government, with 7762 inhabitants; Trois Rivières (5016), Vieux Habitants (3954), Pointe à Pitre (a magnificent port in Grande Terre, with 17,242 inhabitants), Laurentin (4355), Le Gossier (4611), Morne à l'Eau (8442), Le Moule (10,378), Petit Bourg (5110), Petit Canal (6748), Port Louis (4393), Saint Anne (9497), Saint Francis (5265), and others. Grand Bourg, the capital of Marie Galante, has 6901 inhabitants. The administrative authority is vested in a governor, who is assisted by a privy council, and has under his orders a director of the interior, a procurator-general, and a paymaster. There is also an elective general council. The colony is divided into three arrondissements, and comprises thirty-four communes with elective municipalities. Political elections are very eagerly contested, the mulatto or negro element striving more and more to seize the power which has fallen from the hands of the old ruined colonists. The apostolic administrator resides at Basse Terre, where there is an appeal court, on which three civil tribunals are dependent (Basse Terre, Pointe à Pitre, and Marie Galante), besides eleven justices of the peace. The vagrancy problem in the colony is not the least serious which has to be dealt with. There is a *lycée* at Pointe à Pitre with 255 pupils, and a diocesan college at Basse Terre. One hundred and one Government primary schools, with (in 1900) 248 teachers and 10,920 pupils, some conducted by the Roman Catholic orders, are scattered throughout the colony. The budget for 1900 balanced at £198,750, and with the Government grant the expenditure on the colony was brought up to about £260,000. In addition the communes expend about £100,000. Altogether the local administration demands 50 per cent. of the total value of the productions. The garrison consists of only 250 men. About 125,000 acres, or a little more than a fourth part of the area of the colony, is cultivated, against 85,000 acres in 1873. Sugar-cane is still the leading crop, and the other crops are cereals, coffee, cacao, cotton, manioc, yams, and potatoes. The yield of sugar in 1875 amounted to 48,000 tons, in 1888 to 65,000; then, in consequence of the fall in the price, a decadence began, which very seriously affected the prosperity of the colony, and in 1898 the crop only reached 36,000 tons. The importation of coolies from Asia and the concentration of the works in great factories were unable to retard the crisis. The profit from the sugar industry is scarcely 5 per cent. Its centres are St Anne, Pointe à Pitre, and Le Moule. Coffee has not escaped the general depression, and the export in 1898 (670 tons) was only about half of that in 1878. The tendency, however, is to recover, and in 1899 the export was 780 tons. The export of cacao in 1899 was 410 tons. Worthy of mention also is the banana crop (200 tons). Tobacco culture, after a slight recovery, has again fallen away, as has the cultivation of vanilla. Forests cover 100,000 acres on the hills, but being difficult of access they are not worked. In 1898 the colony possessed 22,000 oxen, 11,000 sheep, 33,000 pigs, 8500 horses, and 11,000 asses and mules. Except sulphur and salt (9,900,000 bushels), no mineral substance is worked in Guadeloupe, but the thermal springs of the colony are regarded as valuable. Besides factories for sugar and distilleries for rum, there are establishments for pickled provisions and for chocolate manufacture. The commerce rose to £2,420,000 in 1878; in 1898 it had fallen to £1,450,000, of which £744,000 was for imports and £706,000 for exports. France's share in the former sum was £355,000, in the latter £700,000. The largest items in the list of imports were, in order, farinaceous foods, animal products (hides, &c.), intoxicants, fish, and textiles. After France the United States, Great Britain, and India are the countries most interested in the import trade. The principal items in the exports—all but minute sums, it will be remembered, to France and her colonies—were: sugar, £458,000; coffee, £86,000; cacao, £45,800; rum, £39,500. The totals of the imports and exports in 1899 were almost the same as in 1898: imports, £738,000; exports, £730,000. In 1899, 438 vessels of 221,303 tons (metric) entered and 419 of 187,911 tons cleared. Regular steam service is maintained between the colony and France and Great Britain.

Guam (Guahan or Guajan), the largest island of the Ladrones or Mariannes, a group of islands in the North Pacific, situated in 13° 26′ N. lat. and 144° 39′ E. long., 1823 miles east by south of Hong Kong, 1342 nautical miles south by east of Yokohoma, and 4470 miles west-south-west of San Francisco. It is a United States naval station and port of call, being 1342 miles east of the Philippines and 3337 west by south of the Sandwich Islands (Honolulu). The island is the most southerly of the group, is surrounded by a dozen islets, measures 32 miles from north to south by 9 east to west, and has an area of 224 square miles. In the north it reaches an altitude of 1000 feet in Santa Rosa, and a low ridge runs parallel to the west coast in the southern half of the island. It is wooded in both the north and west. The coast is generally rocky, except in the south-east, where it is coral-built and low. The climate is excellent, with two distinct seasons, and the rainfall is distributed throughout the year. Destructive typhoons sometimes visit the island, and earthquakes occasionally. The principal products are maize, sugar, potatoes, yams, bananas, oranges, and a few cocoanuts and pineapples. The value of the island lies in its fine harbour of San Luis d'Apra or Caldera, on the west coast, measuring 3½ miles across, with a depth of from 4 to 27 fathoms, and divided into an inner and an outer harbour by a peninsula and an island. Besides this there are several other coves and bays round the coast. The inhabitants are of the Chamorro stock (Indonesian), strongly intermixed with Philippine Tagals and Spaniards; and their speech is a dialect of Malay, corrupted by Tagal and Spanish. They number in all (1887), 8353; (1900), 9000, of whom 6185 live in the chief town Agaña, 10 miles north-east of San Luis d'Apra. The island is administered by a naval governor. It was discovered by Magellan in 1521, occupied by Spain in 1688, and ceded to the United States by the Treaty of Paris on 10th December 1898.

Guanabacoa, a town in Cuba, about 6 miles east of Havana, of which it is practically a suburb. Population (1899), 13,965.

Guanajay, a town in Cuba, 22 miles south-west of Havana. It is situated in the midst of a fertile country, about 12 miles from the north shore of Pinar del Rio province. It has a handsome plaza and some imposing houses. Population (1899), 6483.

Guanajuato, a state of Mexico, bounded on the N. by the state of San Luis Potosí, on the E. by that of Queretaro, on the S. by Michoacan, and on the W. by Jalisco. Area, 11,374 square miles. Population (1879), 834,845; (1900), 1,065,317. It is one of the most favoured regions of Mexico, its mining resources, fertility of soil, and railway communications bringing it great prosperity. The climate is temperate, the mean temperature being about 70° F. The principal agricultural products are cereals and leguminous plants of all kinds, tobacco, &c. Hogs, sheep, and goats are the principal animals raised. In 1897 the mineral production amounted to 149,507,042 kilograms, worth $9,026,348. The total trade is about $67,000,000 a year. The Mexican Central Railway traverses the state in three directions. The industries comprise 350 woollen mills, 72 flour mills, distilleries, foundries, tanneries, &c. The state is divided into five departments and thirty-one *partidos*. The capital, Guanajuato, situated 250 miles by rail from Mexico City, has good public buildings, a mint, state college, several churches, two theatres, hospitals, a pantheon, and the castle of Granaditas; population, 39,404. The principal towns of the state are Celaya (21,245), Irapuato (18,593), Silao (15,437), Salamanca (13,121), Allende (12,740), Valle de Santiago (12,671), Salvatierra (11,008), Pozos (9505), Cortazar (8623), La Luz (8318), Penjamo (7558), Santa Cruz (7440), San Francisco del Rincón (7111), Acambaro (6958), Gonzalez (6097), Dolores Hidalgo (5949), Yuriria (5789), Moroleon (5716), Comonfort (5260).

Guantanamo, the easternmost town of the south coast of Cuba. It is the shipping port and centre of a coffee-, sugar-, and lime-growing district. Population (1899), 7137.

Guarantee (sometimes spelt "Guarantie" or "Guaranty").—This word and the word "warrant" are probably both derived from the Teutonic word *wahren*, which signifies to defend or make safe and binding. "Guarantee" is, however, a term more comprehensive and of higher import than either "warrant" or "security," and designates either some international treaty whereby claims, rights, or possessions are secured, or more commonly a mere private transaction, by means of which one person, to obtain some trust, confidence, or credit for another, engages to be answerable for him.

In English law, a guarantee is a contract to answer for the payment of some debt, or the performance of some duty, by a third person who is *primarily* liable to such payment or performance. It is a *collateral* contract, which does not extinguish the original liability or obligation to which it is accessory, but on the contrary is itself rendered null and void should the latter fail, as without a principal there can be no accessory. The liabilities of a surety are in law dependent upon those of the principal debtor, and when the latter cease the former do so likewise (*per* Collins, L.J., in *Stacey* v. *Hill*, 1901, 1 K.B., at p. 666). If, therefore, persons wrongly suppose that a third person is liable to one of them, and a guarantee is given on that erroneous supposition, it is invalid *ab initio*, by virtue of the *lex contractûs*, because its foundation (which was that another was taken to be liable) has failed (*per* Wills, J., in *Mountstephen* v. *Lakeman*, L.R. 7 Q.B., p. 202).

The giver of a guarantee is called "the surety," or "the guarantor"; the person to whom it is given "the creditor," or "the guarantee"; while the person whose payment or performance is secured thereby is termed "the principal debtor," or simply "the principal." In America, but not apparently elsewhere, there is a recognized distinction between "a surety" and "a guarantor"; the former being usually bound with the principal, at the same time and on the same consideration, while the contract of the latter is his own separate undertaking, in which the principal does not join, and in respect of which he is not to be held liable, until due diligence has been exerted to compel the principal debtor to make good his default. There is no privity of contract between the surety and the principal debtor, for the surety contracts with the creditor, and they do not constitute in law one person, and are not jointly liable to the creditor (*per* Baron Parke in *Bain* v. *Cooper*, 1 Dowl. R. (N.S.) 11, 14).

No special phraseology is necessary to the formation of a guarantee; and what really distinguishes such a contract from one of insurance is not any essential difference between the two forms of words *insurance* and *guarantee*, but the substance of the contract entered into by the parties in each particular case (*per* Romer, L.J., in *Seaton* v. *Heath*—*Seaton* v. *Burnand*, 1899, 1 Q.B. 782, 792, C.A.; and see *Dane* v. *Mortgage Insurance Corporation*, 1894, 1 Q.B. 54 C.A.) In this connexion it may be mentioned that the different kinds of suretyships have been classified as follows:—(1) Those in which there is an agreement to constitute, for a particular purpose, the relation of principal and surety, to which agreement the

creditor thereby secured is a party; (2) those in which there is a similar agreement between the principal and surety only, to which the creditor is a stranger; and (3) those in which, without any such contract of suretyship, there is a primary and a secondary liability of two persons for one and the same debt, the debt being, as between the two, that of one of those persons only, and not equally of both, so that the other, if he should be compelled to pay it, would be entitled to reimbursement from the person by whom (as between the two) it ought to have been paid (*per* Earl of Selborne, L.C., in *Duncan Fox and Co.* v. *North and South Wales Bank*, 6 App. Cas., at p. 11).

The common-law requisites of a guarantee in no way differ from those essential to the formation of any other contract. That is to say, they comprise the mutual assent of two or more parties, competency to contract, and, unless the guarantee be under seal, valuable consideration. An offer to guarantee is not binding until it has been accepted, being revocable till then by the party making it. Unless, however, as sometimes happens, the offer contemplates an express acceptance, one may be implied, and it may be a question for a jury whether an offer of guarantee has in fact been accepted. Where the surety's assent to a guarantee has been procured by fraud of the person to whom it is given, there is no binding contract. Such fraud may consist of suppression or concealment or misrepresentation. There is some conflict of authorities as to what facts must be spontaneously disclosed to the surety by the creditor, but it may be taken that the rule on the subject is less stringent than that governing assurances upon marine, life, and other risks (*The North British Insurance Co.* v. *Lloyd*, 10 Exch. 523), though formerly this was denied (*Owen* v. *Homan*, 3 Mac. and G. 378, 397). Moreover, even where the contract relied upon is in the form of a policy guaranteeing the solvency of a surety for another's debt, and is therefore governed by the doctrine of *uberrima fides*, only such facts as are really material to the risk undertaken need be spontaneously disclosed (*Seaton* v. *Burnand—Burnand* v. *Seaton*, 1900, A.C. 135). As regards the competency of the parties to enter into a contract of guarantee, this may be affected by insanity or intoxication of the surety, if known to the creditor, or by disability of any kind. The ordinary disabilities are those of infants and married women—now greatly mitigated as regards the latter by the Married Women's Property Acts, 1870 to 1893, which enable a married woman to contract, as a *feme sole*, to the extent of her separate property. Every guarantee not under seal must have a consideration to support it, though the least spark of one suffices (*per* Wilmot, J., in *Pillan* v. *Van Mierop and Hopkins*, 3 Burr. at p. 1666; *Barrell* v. *Trussell*, 4 Taunt. 117), which, as in other cases, may consist either in some right, interest, profit, or benefit accruing to the one party, or some forbearance, detriment, loss, or responsibility given, suffered, or undertaken by the other. In some guarantees the consideration is entire—as where, in consideration of a lease being granted, the surety becomes answerable for the performance of the covenants; in other cases it is fragmentary, *i.e.*, supplied from time to time—as where a guarantee is given to secure the balance of a running account at a banker's, or a balance of a running account for goods supplied (*per* Lush, L.J., in *Lloyd's* v. *Harper*, 16 Ch. Div., at p. 319). In the former case, the moment the lease is granted there is nothing more for the lessor to do, and such a guarantee as that of necessity runs on throughout the duration of the lease, and is irrevocable. In the latter case, however, unless the guarantee stipulates to the contrary, the surety may at any time terminate his liability under the guarantee as to *future* advances, &c. The consideration for a guarantee must not be *past* or *executed*, but on the other hand it need not comprise a direct benefit or advantage to either the surety or the creditor, but may solely consist of anything done, or any promise made, for the benefit of the principal debtor. It is more frequently *executory* than *concurrent*, taking the form either of forbearance to sue the principal debtor, or of a future advance of money or supply of goods to him. Total failure of the consideration stipulated for by the party giving a guarantee will prevent its being enforced, as will also the existence of an illegal consideration.

The statutory requisites of a guarantee are, in England, prescribed by (1) the Statute of Frauds, which, with reference to guarantees, provides that "no action shall be brought whereby to charge the defendant upon any special promise to answer for the debt, default, or miscarriages of another person, unless the agreement upon which such action shall be brought, or some memorandum or note thereof, shall be in writing and signed by the party to be charged therewith, or some other person thereunto by him lawfully authorized," and (2) Lord Tenterden's Act (9 Geo. IV. c. 14), which by § 6 enacts that "no action shall be brought whereby to charge any person upon or by reason of any representation or assurance made or given concerning or relating to the character, conduct, credit, ability, trade, or dealings of any other person, to the intent or purpose that such other person may obtain credit, money, or goods upon" (*i.e.*, "upon credit," see *per* Parke, B., in *Lyde* v. *Barnard*, 1 M. and W., at p. 104), "unless such representation or assurance be made in writing signed by the party to be charged therewith." This latter enactment, which applies to incorporated companies as well as to individual persons (*Hirst* v. *West Riding Union Banking Co.*, 1901, 2 K.B. 560 C.A.), was rendered necessary by an evasion of the 4th section of the Statute of Frauds, accomplished by treating the special promise to answer for another's debt, default, or miscarriage, when *not* in writing, as required by that section, as a false and fraudulent representation concerning another's credit, solvency, or honesty, in respect of which damages, as for a tort, were held to be recoverable (*Pasley* v. *Freeman*, 3 T.R. 51). In Scotland, where, it should be stated, a guarantee is called a "cautionary obligation," similar enactments to those just specified are contained in § 6 of the Mercantile Law Amendment Act (Scotland), 1856, while in the Irish Statute of Frauds (7 Will. III. c. 12) there is a provision identical with that found in the English Statute of Frauds. In India a guarantee may be either oral or written (Indian Contract Act, § 126).

The Statute of Frauds does not invalidate a verbal guarantee, but renders it unenforceable by action. It may, therefore, be available in support of a defence to an action, and money paid under it cannot be recovered. An indemnity is not a guarantee within the statute, unless it contemplates the primary liability of a third person. It need not, therefore, be in writing when it is a mere promise to become liable for a debt, whenever the person to whom the promise is made should become liable (*Wildes* v. *Dudlow*, L.R. 19 Eq. 198; *Guild* v. *Conrad*, 1894, 2 Q.B. 885 C.A.). Neither does the statute apply to the promise of a *del credere* agent, which binds him, in consideration of the higher commission he receives, to make no sales on behalf of his principal except to persons who are absolutely solvent, and renders him liable for any loss that may result from the non-fulfilment of his promise. A promise to *give* a guarantee is, however, within the statute, though not one to *procure* a guarantee.

The general principles which determine what are guarantees within the Statute of Frauds, as deduced from a multitude of decided cases, are briefly as follows:—(1) the primary liability of a third person must exist or be

contemplated as the foundation of the contract (*Birkmyr* v. *Darnell*, 1 Sm. L.C., 10th ed., p. 287; *Mountstephen* v. *Lakeman*, L.R. 7 Q.B. 196; L.R. 7 H.L. 17); (2) the promise must be made to the creditor; (3) there must be an absence of all liability on the part of the surety independently of his express promise of guarantee; (4) the main object of the transaction between the parties to the guarantee must be the fulfilment of a third party's obligation; and (5) the contract entered into must not amount to a sale by the creditor to the promiser of a security for a debt or of the debt itself (see De Colyar's *Law of Guarantees and of Principal and Surety*, 3rd ed., pp. 65–161, where these principles are discussed in detail by the light of decided cases there cited).

As regards the kind of note or memorandum of the guarantee that will satisfy the Statute of Frauds, it is now provided by § 3 of the Mercantile Law Amendment Act, 1856, that "no special promise to be made, by any person after the passing of this Act, to answer for the debt, default, or miscarriage of another person, being in writing and signed by the party to be charged therewith, or some other person by him thereunto lawfully authorized, shall be deemed invalid to support an action, suit, or other proceeding, to charge the person by whom such promise shall have been made, by reason only that the consideration for such promise does not appear in writing, or by necessary inference from a written document." Prior to this enactment, which is not retrospective in its operation, it was held in many cases that as the Statute of Frauds requires "the agreement" to be in writing, all parts thereof were required so to be, including the consideration moving to, as well as the promise by, the party to be charged (*Wain* v. *Walters*, 5 East, 10; *Saunders* v. *Wakefield*, 4 B. and Ald. 595). These decisions, however, proved to be burdensome to the mercantile community, especially in Scotland and the north of England, and ultimately led to the alteration of the law, so far as guarantees are concerned, by means of the enactment already specified. Any writing embodying the terms of the agreement between the parties, and signed by the party to be charged, is sufficient; and the idea of agreement need not be present to the mind of the person signing (*per* Lindley, L.J., in *In re* Hoyle—*Hoyle* v. *Hoyle*, 1893, 1 Ch., at p. 98). It is, however, necessary that the names of the contracting parties should appear somewhere in writing; that the party to be charged, or his agent, should sign the memorandum or note of agreement, or else should sign another paper referring thereto; and that, when the note or memorandum is made, a complete agreement shall exist. Moreover, the memorandum must have been made before action brought, though it need not be contemporaneous with the agreement itself. As regards the stamping of the memorandum or note of agreement, a guarantee cannot be given in evidence unless properly stamped (Stamp Act, 1891). A guarantee for the payment of goods, however, requires no stamp, being within the exception contained in the first schedule of the Act. Nor is it necessary to stamp a written representation or assurance as to character within 9 Geo. IV. c. 14, *supra*. If under seal, a guarantee requires a ten-shilling stamp; otherwise a sixpenny stamp suffices; and, on certain prescribed terms, the stamps can be affixed any time after execution (Stamp Act, 1891, § 15, amended by § 18 of the Finance Act, 1895).

Extent of surety's liability.

The liability incurred by a surety under his guarantee depends upon its terms, and is not necessarily coextensive with that of the principal debtor. The surety cannot, however, be made liable except for a loss sustained by reason of the default guaranteed against. It was formerly considered to be the duty of the party taking a guarantee to see that it was couched in language enabling the party giving it to understand clearly to what extent he was binding himself (*Nicholson* v. *Paget*, 1 C. and M. 48). This view, however, can no longer be sustained, it being now recognized that a guarantee, like any other contract, must, in cases of ambiguity, be construed against the party bound thereby, and in favour of the party receiving it (*Mayer* v. *Isaac*, 6 M. and W. 605; *Wood* v. *Priestner*, L.R. 2 Exch. 66). The surety is not to be charged beyond the limits prescribed by his contract, which must be construed so as to give effect to what may fairly be inferred to have been the intention of the parties, from what they themselves have expressed in writing. In cases of doubtful import, recourse to parol evidence is permissible, to explain, but not to contradict, the written evidence of the guarantee. As a general rule, the surety is not liable if the principal debt cannot be enforced, because, as already explained, the obligation of the surety is merely accessory to that of the principal debtor. It has never been actually decided in England whether this rule holds good in cases where the principal debtor is an infant, and on that account is not liable to the creditor. Probably in such a case the surety might be held liable by estoppel (see *Kimball* v. *Newell*, 7 Hill (N.Y.) 116). When directors guarantee the performance by their company of a contract which is *ultra vires*, and therefore not binding on the latter, the directors' suretyship liability is, nevertheless, enforceable against them (*Yorkshire Railway Waggon Co.* v. *Maclure*, 21 Ch. D. 309 C.A.).

It is not always easy to determine for how long a time liability under a guarantee endures. Sometimes a guarantee is limited to a single transaction, and is obviously intended to be security against one specific default only. On the other hand, it as often happens that it is not exhausted by one transaction on the faith of it, but extends to a series of transactions, and remains a standing security until it is revoked, either by the act of the parties or else by the death of the surety. It is then termed a continuing guarantee. No fixed rules of interpretation determine whether a guarantee is a continuing one or not, but each case must be judged on its individual merits; and frequently, in order to achieve a correct construction, it becomes necessary to examine the surrounding circumstances, which often reveal what was the subject-matter which the parties contemplated when the guarantee was given, and likewise what was the scope and object of the transaction between them. Most continuing guarantees are either ordinary mercantile securities, in respect of advances made or goods supplied to the principal debtor, or else bonds for the good behaviour of persons in public or private offices or employments. With regard to the latter class of continuing guarantees, the surety's liability is, generally speaking, revoked by any change in the constitution of the persons to or for whom the guarantee is given. On this subject it is now provided by section 18 of the Partnership Act, 1890, which applies to Scotland as well as England, that "a continuing guarantee or cautionary obligation given either to a firm or to a third person in respect of the transactions of a firm, is, in the absence of agreement to the contrary, revoked as to future transactions by any change in the constitution of the firm to which, or of the firm in respect of the transactions of which the guaranty or obligation was given." This section, like the enactment it replaces, namely, section 4 of the Mercantile Law Amendment Act, 1856, is mainly declaratory of the common law, as embodied in decided cases, which indicate that the changes in the persons to or for whom a guarantee is given may consist either of an increase in their number, of a diminution thereof caused by death or retirement from business, or of the incorpora-

tion or consolidation of the persons to whom the guarantee is given. In this connexion it may be stated that the Government Offices (Security) Act, 1875, which has been amended by the Statute Law Revision Act, 1883, contains certain provisions with regard to the acceptance by the heads of public departments of guarantees given by companies for the due performance of the duties of an office or employment in the public service, and enables the Commissioners of His Majesty's Treasury to vary the character of any security, for good behaviour by public servants, given after the passing of the Act.

Before the surety can be rendered liable on his guarantee, the principal debtor must have made default. When, however, this has occurred, the creditor, in the absence of express agreement to the contrary, may sue the surety, without even informing him of such default having taken place, or requiring him to pay, and before proceeding against the principal debtor or resorting to securities for the debt received from the latter. In those countries where the municipal law is based on the Roman civil law, sureties usually possess the right, originally conferred by the Roman law, of compelling the creditor to sue the principal debtor before having recourse to the sureties. This right, according to a great American jurist (Chancellor Kent in *Hayes* v. *Ward*, 4 Johns. New York, Ch. Cas. p. 132), "accords with a common sense of justice and the natural equity of mankind." In England, however, this right has never been fully recognized; but, even in England, before any demand for payment has been made by the creditor on the surety, the latter can, as soon as the principal debtor has made default, compel the creditor, on giving him an indemnity against costs and expenses, to sue the principal debtor, if the latter be solvent and able to pay (*per* A. L. Smith, L.J., in *Rouse* v. *Bradford Banking Company*, 1894, 2 Ch. p. 75; *per* Lord Eldon in *Wright* v. *Simpson*, 6 Ves. at p. 733)

The usual mode of enforcing liability under a guarantee is by action in the High Court or in the County Court. It is also permissible for the creditor to obtain redress by means of a set-off or counter-claim, in an action brought against him by the surety. On the other hand, the surety may now, in any court in which the action or the guarantee is pending, avail himself of any set-off which may exist between the principal debtor and the creditor. Moreover, if one of several sureties for the same debt is sued by the creditor or his guarantee, he can, by means of a proceeding termed a third-party notice, claim contribution from his co-surety towards the common liability. Independent proof of the surety's liability under his guarantee must always be given at the trial; as the creditor cannot rely either on admissions made by the principal debtor, or on a judgment or award obtained against him (*Ex parte* Young *In re* Kitchin, 17 Ch. Div. 668). Should the surety become bankrupt either before or after default has been made by the principal debtor, the creditor will have to prove against his estate. This right of proof is now regulated by the 37th section of the Bankruptcy Act, 1883, which is most comprehensive in its terms.

Rights of sureties.

A person liable as a surety for another under a guarantee possesses various rights against him, against the person to whom the guarantee is given, and also against those who may have become co-sureties in respect of the same debt, default, or miscarriage. As regards the surety's rights against the principal debtor, the latter may, after he has made default, be compelled by the surety to exonerate him from liability by payment of the guaranteed debt (*per* Sir W. Grant, M.R., in *Antrobus* v. *Davidson*, 3 Meriv. 569, 579; *per* Lindley, L.J., in *Johnston* v. *Salvage Association*, 19 Q.B.D. 460, 461; and see *Wolmershausen* v. *Gullick*, 1893, 2 Ch. 514). The moment, moreover, the surety has himself paid any portion of the guaranteed debt, he is entitled, if the suretyship was undertaken at the principal debtor's actual or constructive request, but not otherwise, to rank as a creditor for the amount so paid, and to compel repayment thereof. In the event of the principal debtor's bankruptcy, the surety can prove against his estate, not only in respect of payments made before such bankruptcy, but also, it seems, in respect of the contingent liability to pay under the guarantee. As regards the rights of the surety against the creditor, they are exercisable even by one who in the first instance was a principal debtor, but has since become a surety, by arrangement with his creditor, duly notified to the creditor, though not even sanctioned by him. This was decided by the House of Lords in the case of *Rouse* v. *The Bradford Banking Co.* (1894, A.C. 586), removing a doubt created by the previous case of *Swire* v. *Redman* (1 Q.B.D. 536), which must now be treated as overruled. The surety's principal right against the creditor entitles him, after payment of the guaranteed debt, to the benefit of all securities, whether known to him (the surety) or not, which the creditor held against the principal debtor; and where, by default or *laches* of the creditor, such securities have been lost, or rendered otherwise unavailable, the surety is discharged *pro tanto*. This right, which is *not* in abeyance till the surety is called on to pay (*Dixon* v. *Steel*, 1901, 2 Ch. 602), extends to all securities, whether satisfied or not, given before or after the contract of suretyship was entered into. On this subject the Mercantile Law Amendment Act, 1856, § 5, provides that "every person, who being surety for the debt or duty of another, or being liable with another for any debt or duty, shall pay such debt or perform such duty, shall be entitled to have assigned to him, or to a trustee for him, every judgment, specialty, or other security, which shall be held by the creditor in respect of such debt or duty, whether such judgment, specialty, or other security shall or shall not be deemed at law to have been satisfied by the payment of the debt or performance of the duty, and such person shall be entitled to stand in the place of the creditor, and to use all the remedies, and, if need be, and upon a proper indemnity, to use the name of the creditor, in any action or other proceeding at law or in equity, in order to obtain from the principal debtor, or any co-surety, co-contractor, or co-debtor, as the case may be, indemnification for the advances made and loss sustained by the person who shall have so paid such debt or performed such duty; and such payment or performance so made by such surety shall not be pleadable in bar of any such action or other proceeding by him, provided always that no co-surety, co-contractor, or co-debtor shall be entitled to recover from any other co-surety, co-contractor, or co-debtor, by the means aforesaid, more than the just proportion to which, as between those parties themselves, such last-mentioned person shall be justly liable." This enactment is so far retrospective that it applies to a contract made before the Act, where the breach thereof, and the payment by the surety, have taken place subsequently. On the principal debtor becoming a bankrupt, the surety who has paid the guaranteed debt has a right to all dividends received by the creditor from the bankrupt in respect thereof, and to stand in the creditor's place as to future dividends. This right is, however, often waived by the guarantee stipulating that, until the creditor has received full payment of all sums due to him from the principal debtor, the surety shall not participate in any dividends distributed from the bankrupt's estate amongst his creditors.

As regards the rights of the surety against a co-surety, he is entitled to contribution from him in respect of their common liability. This particular right is not the result of

any contract, but is derived from a general equity, on the ground of equality of burden and benefit, and exists whether the sureties be bound jointly, or jointly and severally, and by the same, or different, instruments. There is, however, no right of contribution where each surety is severally bound for a given portion only of the guaranteed debt; nor in the case of a surety for a surety; nor where a person becomes a surety jointly with another, and at the latter's request. Contribution may be enforced, either before payment, or as soon as the surety has paid more than his share of the common debt (*Wolmershausen* v. *Gullick*, 1893, 2 Ch. 514); and the amount recoverable is now always regulated by the number of solvent sureties, though formerly this rule only prevailed in equity. The right of contribution is not the only right possessed by co-sureties against each other, but they are also entitled to the benefit of all securities which have been taken by any one of them as an indemnity against the liability incurred for the principal debtor.

The discharge of a surety from liability under his guarantee may be accomplished in various ways, he being regarded as a "favoured debtor" (*per* Turner, L.J., in *Wheatley* v. *Bastow*, 7 De G. M. and G. 279, 280; *per* Earl of Selborne, L.C., in *In re* Sherry—*London and County Banking Co.* v. *Terry*, 25 Ch. D., at p. 703). Thus, fraud subsequent to the execution of the guarantee (as where, for example, the creditor connives at the principal debtor's default) will certainly discharge the surety. Again, a material alteration made in the instrument of guarantee after its execution may also have this effect. The most prolific ground of discharge, however, is usually traceable to causes originating in the creditor's *laches* or conduct, the governing principle being that if the creditor violates any rights which the surety possessed when he entered into the suretyship, even though the damage be nominal only, the guarantee cannot be enforced. On this subject it suffices to state that the surety's discharge may be accomplished (1) by a variation of the terms of the contract between the creditor and the principal debtor, or of that subsisting between the creditor and the surety; (2) by the creditor taking a new security from the principal debtor in lieu of the original one; (3) by the creditor discharging the principal debtor from liability; (4) by the creditor binding himself to give time to the principal debtor for payment of the guaranteed debt; or (5) by loss of securities received by the creditor in respect of the guaranteed debt. A revocation of the contract of suretyship by act of the parties, or in certain cases by the death of the surety, may also operate to discharge the surety. The death of a surety does not *per se* determine the guarantee, but, save where from its nature the guarantee is irrevocable by the surety himself, it can be revoked by express notice after his death, or, it would appear, by the creditor becoming affected with constructive notice thereof; except where, under the testator's will, the executor has the option of continuing the guarantee, in which case the executor should, it seems, specifically withdraw the guarantee in order to determine it. Where one of a number of joint and several sureties dies, the future liability of the survivors under the guarantee continues, at all events until it has been determined by express notice. Moreover, when three persons joined in a guarantee to a bank, and their liability thereunder was not expressed to be several, it was held that the death of one surety did not determine the liability of the survivors. In such a case, however, the estate of the deceased surety would be relieved from liability.

The Statutes of Limitation bar the right of action on guarantees under seal after twenty years, and on other guarantees after six years, from the date when the creditor might have sued the surety.

(H. A. DE C.)

Guarda, a district of Portugal, on the watershed between the Tagus and the Douro, with an area of 2086 square miles, and a population of 263,292 in 1900. Wine is the principal product, especially in the communes of Foscôa, Mêda, Gouveia, and Ceia. Corn, *i.e.*, wheat, millet, barley, and rye, is also extensively cultivated. Woollens are made at Gouveia, Manteigas, and Guarda. The live stock, consisting principally of sheep, are estimated to amount (in value) to 3·4 per cent. of the entire kingdom. The capital, GUARDA, an episcopal see, stands on a plateau at the north end of the Serra da Estrella, 81 miles south-east of Oporto. It has a sanatorium for consumptives. Population, 5990.

Guatemala, a country of Central America, lying between 13° 42′ and 17° 49′ N. lat., and 88° 10′ and 92° 30′ W. long. The frontier towards Mexico was determined by conventions of 27th September 1882, 17th October 1883, 1st April 1895, and 8th May 1899. Starting from the Pacific, it ascends the river Suchiate, then follows an irregular line towards the north-east, till it reaches the parallel of 17° 49′ N. lat., along which it runs to the frontier of British Honduras. This frontier, by the convention of 9th July 1893, coincides with the meridian of 89° 20′ W. long. till it meets the river Sarstun, which it follows eastwards to the Gulf of Honduras. The climate is healthy, except on the coast lands, where malarial fever is prevalent. The rainy season in the interior lasts from May to October, but on the coast sometimes continues till December. The coldest month is January, and the warmest is May. The average temperatures for these months at places of different altitudes are given by Dr Sapper as follows:—

Locality.	Altitude (Feet).	Fahrenheit Degrees.	
		January.	May.
Puerto Barrios	6	74	81
Salamá	3020	68	77
Campur	3050	64	73
Chimax	4280	61	68
Guatemala	4870	60	67
Quezaltenango	7710	50	62

Area and Population.—The area is calculated at 48,300 square miles, and the population in 1900 was put at 1,574,340.

According to the returns of the census taken 26th February 1893, the population was 1,364,678 (females, 687,206; males, 677,472), of whom 882,733 were Indians: about 60 per cent. of the population are Indians, the rest are Ladinos, people of mixed blood, negroes, mulattoes, zambos, and half-caste Indians, the number of pure whites being very small. The foreign population (1893) numbered 11,331, including 1303 Americans (mostly Jews from the west), 532 Spaniards, 453 Italians, 399 Germans, 349 English, 272 French. By occupation, 327,594 persons were labourers, 46,054 bakers, 21,930 weavers, 13,034 merchants, 9653 seamstresses, 7759 servants and female cooks. The rural population numbered 827,058; inhabitants of cities and towns, 526,666; and those of special settlements, 10,954.

The principal towns, with their populations in 1893, are: Guatemala, 72,000; Quezaltenango, 16,000[1]; Antigua, 9000; Atitlán, 9000; San Cristóbal, 9000; Momostenango, 8000; Tacaná, 7000; Cobán, 6000; Nebaj, 6000; Totonicapam, 5000; Escuintla, 5000.

[1] This town was entirely destroyed at the end of April 1902 by an earthquake, but preparations for its rebuilding were promptly begun.

tion or consolidation of the persons to whom the guarantee is given. In this connexion it may be stated that the Government Offices (Security) Act, 1875, which has been amended by the Statute Law Revision Act, 1883, contains certain provisions with regard to the acceptance by the heads of public departments of guarantees given by companies for the due performance of the duties of an office or employment in the public service, and enables the Commissioners of His Majesty's Treasury to vary the character of any security, for good behaviour by public servants, given after the passing of the Act.

Before the surety can be rendered liable on his guarantee, the principal debtor must have made default. When, however, this has occurred, the creditor, in the absence of express agreement to the contrary, may sue the surety, without even informing him of such default having taken place, or requiring him to pay, and before proceeding against the principal debtor or resorting to securities for the debt received from the latter. In those countries where the municipal law is based on the Roman civil law, sureties usually possess the right, originally conferred by the Roman law, of compelling the creditor to sue the principal debtor before having recourse to the sureties. This right, according to a great American jurist (Chancellor Kent in *Hayes* v. *Ward*, 4 Johns. New York, Ch. Cas. p. 132), "accords with a common sense of justice and the natural equity of mankind." In England, however, this right has never been fully recognized; but, even in England, before any demand for payment has been made by the creditor on the surety, the latter can, as soon as the principal debtor has made default, compel the creditor, on giving him an indemnity against costs and expenses, to sue the principal debtor, if the latter be solvent and able to pay (*per* A. L. Smith, L.J., in *Rouse* v. *Bradford Banking Company*, 1894, 2 Ch. p. 75; *per* Lord Eldon in *Wright* v. *Simpson*, 6 Ves. at p. 733)

The usual mode of enforcing liability under a guarantee is by action in the High Court or in the County Court. It is also permissible for the creditor to obtain redress by means of a set-off or counter-claim, in an action brought against him by the surety. On the other hand, the surety may now, in any court in which the action or the guarantee is pending, avail himself of any set-off which may exist between the principal debtor and the creditor. Moreover, if one of several sureties for the same debt is sued by the creditor or his guarantee, he can, by means of a proceeding termed a third-party notice, claim contribution from his co-surety towards the common liability. Independent proof of the surety's liability under his guarantee must always be given at the trial; as the creditor cannot rely either on admissions made by the principal debtor, or on a judgment or award obtained against him (*Ex parte* Young *In re* Kitchin, 17 Ch. Div. 668). Should the surety become bankrupt either before or after default has been made by the principal debtor, the creditor will have to prove against his estate. This right of proof is now regulated by the 37th section of the Bankruptcy Act, 1883, which is most comprehensive in its terms.

Rights of sureties.

A person liable as a surety for another under a guarantee possesses various rights against him, against the person to whom the guarantee is given, and also against those who may have become co-sureties in respect of the same debt, default, or miscarriage. As regards the surety's rights against the principal debtor, the latter may, after he has made default, be compelled by the surety to exonerate him from liability by payment of the guaranteed debt (*per* Sir W. Grant, M.R., in *Antrobus* v. *Davidson*, 3 Meriv. 569, 579; *per* Lindley, L.J., in *Johnston* v. *Salvage Association*, 19 Q.B.D. 460, 461; and see *Wolmershausen* v. *Gullick*, 1893, 2 Ch. 514). The moment, moreover, the surety has himself paid any portion of the guaranteed debt, he is entitled, if the suretyship was undertaken at the principal debtor's actual or constructive request, but not otherwise, to rank as a creditor for the amount so paid, and to compel repayment thereof. In the event of the principal debtor's bankruptcy, the surety can prove against his estate, not only in respect of payments made before such bankruptcy, but also, it seems, in respect of the contingent liability to pay under the guarantee. As regards the rights of the surety against the creditor, they are exercisable even by one who in the first instance was a principal debtor, but has since become a surety, by arrangement with his creditor, duly notified to the creditor, though not even sanctioned by him. This was decided by the House of Lords in the case of *Rouse* v. *The Bradford Banking Co.* (1894, A.C. 586), removing a doubt created by the previous case of *Swire* v. *Redman* (1 Q.B.D. 536), which must now be treated as overruled. The surety's principal right against the creditor entitles him, after payment of the guaranteed debt, to the benefit of all securities, whether known to him (the surety) or not, which the creditor held against the principal debtor; and where, by default or *laches* of the creditor, such securities have been lost, or rendered otherwise unavailable, the surety is discharged *pro tanto*. This right, which is *not* in abeyance till the surety is called on to pay (*Dixon* v. *Steel*, 1901, 2 Ch. 602), extends to all securities, whether satisfied or not, given before or after the contract of suretyship was entered into. On this subject the Mercantile Law Amendment Act, 1856, § 5, provides that "every person, who being surety for the debt or duty of another, or being liable with another for any debt or duty, shall pay such debt or perform such duty, shall be entitled to have assigned to him, or to a trustee for him, every judgment, specialty, or other security, which shall be held by the creditor in respect of such debt or duty, whether such judgment, specialty, or other security shall or shall not be deemed at law to have been satisfied by the payment of the debt or performance of the duty, and such person shall be entitled to stand in the place of the creditor, and to use all the remedies, and, if need be, and upon a proper indemnity, to use the name of the creditor, in any action or other proceeding at law or in equity, in order to obtain from the principal debtor, or any co-surety, co-contractor, or co-debtor, as the case may be, indemnification for the advances made and loss sustained by the person who shall have so paid such debt or performed such duty; and such payment or performance so made by such surety shall not be pleadable in bar of any such action or other proceeding by him, provided always that no co-surety, co-contractor, or co-debtor shall be entitled to recover from any other co-surety, co-contractor, or co-debtor, by the means aforesaid, more than the just proportion to which, as between those parties themselves, such last-mentioned person shall be justly liable." This enactment is so far retrospective that it applies to a contract made before the Act, where the breach thereof, and the payment by the surety, have taken place subsequently. On the principal debtor becoming a bankrupt, the surety who has paid the guaranteed debt has a right to all dividends received by the creditor from the bankrupt in respect thereof, and to stand in the creditor's place as to future dividends. This right is, however, often waived by the guarantee stipulating that, until the creditor has received full payment of all sums due to him from the principal debtor, the surety shall not participate in any dividends distributed from the bankrupt's estate amongst his creditors.

As regards the rights of the surety against a co-surety, he is entitled to contribution from him in respect of their common liability. This particular right is not the result of

any contract, but is derived from a general equity, on the ground of equality of burden and benefit, and exists whether the sureties be bound jointly, or jointly and severally, and by the same, or different, instruments. There is, however, no right of contribution where each surety is severally bound for a given portion only of the guaranteed debt; nor in the case of a surety for a surety; nor where a person becomes a surety jointly with another, and at the latter's request. Contribution may be enforced, either before payment, or as soon as the surety has paid more than his share of the common debt (*Wolmershausen* v. *Gullick*, 1893, 2 Ch. 514); and the amount recoverable is now always regulated by the number of solvent sureties, though formerly this rule only prevailed in equity. The right of contribution is not the only right possessed by co-sureties against each other, but they are also entitled to the benefit of all securities which have been taken by any one of them as an indemnity against the liability incurred for the principal debtor.

The discharge of a surety from liability under his guarantee may be accomplished in various ways, he being regarded as a "favoured debtor" (*per* Turner, L.J., in *Wheatley* v. *Bastow*, 7 De G. M. and G. 279, 280; *per* Earl of Selborne, L.C., in *In re* Sherry—*London and County Banking Co.* v. *Terry*, 25 Ch. D., at p. 703). Thus, fraud subsequent to the execution of the guarantee (as where, for example, the creditor connives at the principal debtor's default) will certainly discharge the surety. Again, a material alteration made in the instrument of guarantee after its execution may also have this effect. The most prolific ground of discharge, however, is usually traceable to causes originating in the creditor's *laches* or conduct, the governing principle being that if the creditor violates any rights which the surety possessed when he entered into the suretyship, even though the damage be nominal only, the guarantee cannot be enforced. On this subject it suffices to state that the surety's discharge may be accomplished (1) by a variation of the terms of the contract between the creditor and the principal debtor, or of that subsisting between the creditor and the surety; (2) by the creditor taking a new security from the principal debtor in lieu of the original one; (3) by the creditor discharging the principal debtor from liability; (4) by the creditor binding himself to give time to the principal debtor for payment of the guaranteed debt; or (5) by loss of securities received by the creditor in respect of the guaranteed debt. A revocation of the contract of suretyship by act of the parties, or in certain cases by the death of the surety, may also operate to discharge the surety. The death of a surety does not *per se* determine the guarantee, but, save where from its nature the guarantee is irrevocable by the surety himself, it can be revoked by express notice after his death, or, it would appear, by the creditor becoming affected with constructive notice thereof; except where, under the testator's will, the executor has the option of continuing the guarantee, in which case the executor should, it seems, specifically withdraw the guarantee in order to determine it. Where one of a number of joint and several sureties dies, the future liability of the survivors under the guarantee continues, at all events until it has been determined by express notice. Moreover, when three persons joined in a guarantee to a bank, and their liability thereunder was not expressed to be several, it was held that the death of one surety did not determine the liability of the survivors. In such a case, however, the estate of the deceased surety would be relieved from liability.

The Statutes of Limitation bar the right of action on guarantees under seal after twenty years, and on other guarantees after six years, from the date when the creditor might have sued the surety.

(H. A. DE C.)

Guarda, a district of Portugal, on the watershed between the Tagus and the Douro, with an area of 2086 square miles, and a population of 263,292 in 1900. Wine is the principal product, especially in the communes of Foscõa, Mêda, Gouveia, and Ceia. Corn, *i.e.*, wheat, millet, barley, and rye, is also extensively cultivated. Woollens are made at Gouveia, Manteigas, and Guarda. The live stock, consisting principally of sheep, are estimated to amount (in value) to 3·4 per cent. of the entire kingdom. The capital, GUARDA, an episcopal see, stands on a plateau at the north end of the Serra da Estrella, 81 miles south-east of Oporto. It has a sanatorium for consumptives. Population, 5990.

Guatemala, a country of Central America, lying between 13° 42′ and 17° 49′ N. lat., and 88° 10′ and 92° 30′ W. long. The frontier towards Mexico was determined by conventions of 27th September 1882, 17th October 1883, 1st April 1895, and 8th May 1899. Starting from the Pacific, it ascends the river Suchiate, then follows an irregular line towards the north-east, till it reaches the parallel of 17° 49′ N. lat., along which it runs to the frontier of British Honduras. This frontier, by the convention of 9th July 1893, coincides with the meridian of 89° 20′ W. long. till it meets the river Sarstun, which it follows eastwards to the Gulf of Honduras. The climate is healthy, except on the coast lands, where malarial fever is prevalent. The rainy season in the interior lasts from May to October, but on the coast sometimes continues till December. The coldest month is January, and the warmest is May. The average temperatures for these months at places of different altitudes are given by Dr Sapper as follows:—

Locality.	Altitude (Feet).	Fahrenheit Degrees.	
		January.	May.
Puerto Barrios	6	74	81
Salamá	3020	68	77
Campur	3050	64	73
Chimax	4280	61	68
Guatemala	4870	60	67
Quezaltenango	7710	50	62

Area and Population.—The area is calculated at 48,300 square miles, and the population in 1900 was put at 1,574,340.

According to the returns of the census taken 26th February 1893, the population was 1,364,678 (females, 687,206; males, 677,472), of whom 882,733 were Indians: about 60 per cent. of the population are Indians, the rest are Ladinos, people of mixed blood, negroes, mulattoes, zambos, and half-caste Indians, the number of pure whites being very small. The foreign population (1893) numbered 11,331, including 1303 Americans (mostly Jews from the west), 532 Spaniards, 453 Italians, 399 Germans, 349 English, 272 French. By occupation, 327,594 persons were labourers, 46,054 bakers, 21,930 weavers, 13,034 merchants, 9653 seamstresses, 7759 servants and female cooks. The rural population numbered 827,058; inhabitants of cities and towns, 526,666; and those of special settlements, 10,954.

The principal towns, with their populations in 1893, are: Guatemala, 72,000; Quezaltenango, 16,000[1]; Antigua, 9000; Atitlán, 9000; San Cristóbal, 9000; Momostenango, 8000; Tacaná, 7000; Cobán, 6000; Nebaj, 6000; Totonicapam, 5000; Escuintla, 5000.

[1] This town was entirely destroyed at the end of April 1902 by an earthquake, but preparations for its rebuilding were promptly begun.

Government.—According to the constitution of 1879, the legislative power is vested in a national assembly of 69 deputies (1 for every 20,000 inhabitants) chosen for 4 years by direct popular vote in 38 electoral districts. The president of the Republic is elected in a similar manner, but for 6 years, and he is not eligible for the following term. He is assisted by 6 ministers, heads of Government departments, and by a council of state of 9 members, 4 of whom are appointed by himself and 5 by the national assembly. The two vice-presidents of the Republic are elected by the national assembly.

Local Government.—Each of the 22 departments is administered by an official called a *Jefe Politico*, or political chief, appointed by the president of the Republic, and each is subdivided into municipal districts, of which there are altogether 331. These districts are administered by one or more *alcaldes* or mayors, assisted by municipal councils, both *alcaldes* and councils being chosen by the people.

Justice.—The judicial power is vested in a supreme court, consisting of a chief-justice and four associate justices, elected by the people; six appeal courts, each with three judges, also elected by the people; and twenty-nine courts of first instance, each consisting of one judge appointed by the president, and two by the chief-justice of the supreme court.

Religion and Instruction.—The prevailing form of religion is the Roman Catholic, but the state recognizes no distinction of creed. The establishment of conventual or monastic institutions is prohibited. Of the population in 1893, 90 per cent. could neither read nor write, 2 per cent. could only read, and 8 per cent. could read and write. Primary instruction is compulsory, and, in Government schools, is provided at the cost of the state. In 1895 there were 1266 Government schools, with a total attendance of 64,015 (39,411 boys and 24,604 girls). But there are, besides, about 50 private (occasionally aided) schools of similar character, owners of plantations on which there are more than 10 children being obliged to provide school accommodation. Higher instruction is given in two national institutes at the capital, one for men with 500 pupils, and one for women with 300. At Quezaltenango there are two similar institutes, and at Chiquimula there are other two. To each of the six there is a normal school attached, and within the Republic there are 4 other normal schools. For professional instruction (law, medicine, engineering) there are 4 schools, supported by private funds, but aided occasionally by the Government. Other educational establishments are a school of art, a national conservatory of music, a commercial college, 4 trades' schools with more than 600 pupils, and a national library. For the year 1901 the expenditure of the state on instruction was put at 1,513,900 pesos.

Defence.—For the white and mixed population military service is compulsory; from the eighteenth to the twenty-fifth year of age, in the active army, and from the twenty-sixth to the fiftieth, in the reserve. The effective force of the active army is put at 56,900, of the reserve at 29,400.

Finance.—Of the revenue of Guatemala about 36 per cent. is derived from liquor and tobacco taxes; 28 per cent. from import and export duties; 9 per cent. from property, road, military, slaughter, and salt taxes; 1·7 per cent. from the gunpowder monopoly; and the remainder from various taxes, stamps, Government lands, and postal and telegraph services. The spending departments are chiefly those of war, government, and internal development. The gold value of the currency peso fluctuates between limits so wide that conversion into sterling (especially for a series of years), with any pretension to accuracy, is impracticable. In 1899 the rate of exchange moved between 710 per cent. and 206 per cent. premium on gold. Between 1892 and 1899 the gross revenues collected were as follows in currency pesos:—

Year.	Pesos.	Year.	Pesos.
1892	8,660,490	1896	15,150,740
1893	10,442,750	1897	12,479,740
1894	11,851,030	1898	9,738,661
1895	14,491,670	1899	8,566,910

The cash receipts and expenditure of the Treasury for 1896–99 were:—

Year.	Receipts.	Expenditure.
	Pesos.	Pesos.
1896	18,351,900	17,437,450
1897	22,073,590	21,433,190
1898	9,183,340	9,964,830
1899	5,946,120	5,937,281

For the year 1900–1 the revenue was estimated at 9,620,000 pesos, and the expenditure at 9,611,200 pesos.

At the end of 1899 the outstanding debt of the Republic was as follows:—

Consolidated external debt	£1,542,112
Muller and Thomsen loan	39,275
German syndicate loan (1897) . . .	101,500
German syndicate loan (1898) . . .	24,850
Other gold debts	109,745
Silver debt (internal loans, note issue, &c.), 25,763,776 pesos = ...	1,167,000
Total	2,984,482

The amount of the consolidated external debt includes arrears of interest. An agreement made in 1895 for the service of this debt was speedily broken by the Government, and another, made in 1898, fared little better, the funds assigned as security for its service being applied to the reduction of the more recent debts due to the German syndicates. At the end of 1899 the assets of the Republic, including national lands, railways, &c., were put at 32,535,300 silver pesos (£2,400,000).

Production.—The most important products of Guatemala are coffee and sugar, and the richest districts for the cultivation of these crops are on the Pacific slope of the range of volcanic mountains running parallel to the coast. On the Atlantic side of the mountains there are also coffee plantations, but in this region progress has been slower. Both in the west and east the most flourishing are the German plantations, which have a total area of more than 1000 square miles, and yield about one-third of the total coffee produce of Guatemala. In both regions the uncultivated land is overgrown with dense tropical forest, the area of which has perceptibly diminished only in the west. The extension of coffee cultivation is shown by the increase of the crop at intervals of five years since 1881, as follows:—

Year.	Lbs.	Year.	Lbs.
1881	26,037,200	1897	82,475,585
1886	52,975,100	1898	82,603,283
1891	52,449,500	1899	84,194,460
1896	68,773,633		

Sugar, which was largely exported from 1882 to 1890, is now again grown in considerable quantities. In 1898 the area under sugar-cane was 40,768 acres, and the yield amounted to 11,356,900 lb of white sugar, 141,620 bags of brown sugar, 13,494,425 lb of molasses, and 3,482,900 lb of inferior sugar. Cocoa-trees are planted in the lowlands to the number of 1,251,830, on an area of 7504 acres, the yield amounting in 1899 to 187,200 lb. There were 11,872 acres under bananas, yielding 910,500 bunches. Tobacco covered 1680 acres, yielding 935,000 lb. Cereals and other agricultural produce grown in small quantities include wheat, potatoes, rice, maize (860,167 bushels on 221,648 acres in 1898), beans (29,310 bushels on 15,456 acres). Rubber-trees are planted in the lowlands, and the production increases. In 1899 the export amounted to 513,800 lb. The cattle industry is prosperous, and hides and skins are exported. In 1898 the live stock within the Republic consisted of 196,768 cattle, 50,343 horses, 77,593 sheep, and 29,784 swine. Gold washing is carried on by natives in a primitive manner on the banks of the Motagua river in the departments of Izabal and Baja Verapaz. Salt mines abound in the departments of Alta Verapaz and Santa Rosa. Silver, iron, copper, lead, cinnabar, coal, and mica are found in different localities on the eastern side of the Republic. Mining, however, has not been undertaken on a large scale, and it is still doubtful whether the minerals known to exist in the country could be obtained in paying quantities. There are no manufactures of any importance. Coarse cotton and woollen stuffs are woven, and hats, shoes, agricultural implements, and other articles are made, but not in sufficient quantities to supply local demands.

Commerce.—The imports into Guatemala consist mainly of cotton goods and yarn, flour, sacks, and iron implements. The exports are coffee, sugar, and a few other products. The imports during the five years 1891–95 were of the average annual value (5 gold pesos = £1) of £1,442,000; in the year 1896, £1,828,670; in 1897, £1,373,600; in 1898, £970,160. The exports in the years 1891–95 amounted to the average annual value of (at 13·5 silver pesos = £1) £1,431,700; in 1896, £1,710,000; in 1897, £1,464,800; in 1898, £1,139,000; in 1899, £1,674,000. In 1899 the values of the principal exports were: coffee, £1,478,100; sugar, £50,070; bananas, £23,610; rubber, £51,380; hides and skins, £53,550; cocoa, £193. Of the imports, about 90 per cent. in value come from the four countries named in the following table, which shows the value imported from each of them in 1898 and 1899. It should be remembered that German trade is much assisted by the numerous German planters within the Republic:—

Countries.	1898	1899.
United States .	£309,829	£227,369
Great Britain .	129,689	157,429
Germany . . .	187,568	133,051
France . . .	43,467	35,728

Of the exports, the United States in 1899 took about 18 per cent. of the coffee, all the bananas, and 50 per cent. of the rubber; Great Britain took 22 per cent. of the coffee and 15 per cent. of the rubber; Germany took 55 per cent. of the coffee and 33 per cent. of the rubber.

Shipping and Communications.—The Republic is in regular steam communication on the Atlantic side with New Orleans, New York, and Hamburg, by vessels which visit the ports of Barrios and Livingston. On the western side the ports of San José, Champerico, and Ocós are visited by the Pacific mail steamers, by the vessels of a Hamburg company, and by those of the South American (Chilian) and the Pacific Steam Navigation Companies. In 1898 altogether 825 vessels entered and 845 cleared at the ports of the Republic. The principal towns are connected by waggon roads, towards the construction and maintenance of which each male inhabitant is required to pay two pesos or give four days' work a year. There are coach routes between the capital and Quezaltenango and Antigua, but over a great portion of the country transport is still on mule-back. The railways in operation are the Southern (or Central), 75 miles, from the capital to San José, belonging to an American company; the Western, 41 miles, from Champerico to Retalhuleu and San Filipé, belonging to a Guatemalan company, but largely under German management; and the Northern, 133 miles, from Port Barrios to El Rancho, a Government line, which is intended to be continued to Guatemala city (60 miles), so that, with the Southern railway, there may be an interoceanic system. For local traffic there are several lines; one from Iztapa, near San José, to Naranjo, and another from Ocós to the western coffee plantations. On the Atlantic slope transport is effected mainly by river tow-boats from Livingston along the Dulce Gulf and other lakes, and the Polochie river as far as Panzos. The narrow-gauge railway that serves the German plantations in the Verapaz region is largely owned by Germans.

Post and Telegraph.—Guatemala joined the Postal Union in 1881, but the international postal service has suffered from the financial rottenness of the Government, which was in debt to the Panama Railway Company and to a New Orleans steamboat company for conveyance of mail packets. The international postal movement in 1899 comprised the despatch of 328,112 and the receipt of 401,598 letters and packets. The total movement in 1898 consisted of the receipt of 2,769,543 and the despatch of 2,771,035 pieces of mail. In 1899 the telegraph lines had a length of 3126 miles, with 148 offices, through which 786,046 messages were sent. In and around the capital and Quezaltenango telephone services have been provided by private companies.

Money and Credit.—Within the Republic there are six banks of issue, to which the Government is deeply indebted. There is practically neither gold nor silver in circulation, and the value of the bank-notes is so fluctuating that trade is seriously hampered. In order to ease its own position and give general relief at a time of financial crisis the Government, on 29th October 1898, empowered a committee of the banks to increase the note circulation by the issue of 6,000,000 pesos of paper money in 1-, 5-, and 25-peso notes. This arrangement did not include a supply of fractional money necessary for retail transactions, and during the last six months of 1899 the only notes of smaller denomination than a peso were the *cedulas*, issued by municipalities, and current only within their several limits. In the course of 1899 fractional silver coins, ·500, ·600, and ·835 fine, were put in circulation to the nominal value of 346,373 pesos, but these, vanishing as soon as issued, made no appreciable difference. In August 1899 the Government made a further contract by which the banks that were parties to it were each authorized to issue, in addition to their earlier issues, small notes to the amount of 100,000 pesos. Since then other issues of small notes have been authorized to take the place of notes of larger denomination; and a later measure provided for the coining of 3,000,000 pesos of fractional nickel money, which will be legal tender only for payment of amounts strictly limited. The silver peso, the monetary unit, weighs 25 grammes ·900 fine. The metric system of weights and measures has been adopted.

History.—The recent history of Guatemala is mainly a record of political, military, and financial trouble. President Rufino Barrios, elected in 1873, governed the country after the manner of a dictator; and though he encouraged education, promoted railway and other enterprises, and succeeded in settling difficulties as to the Mexican boundary, the general result of his policy was baneful. Conspiracies against him were rife, and in 1884 he narrowly escaped assassination. His ambition was to be the restorer of the federal union of the Central American States, and when his efforts towards this end by peaceful means failed, he had recourse to the sword. Counting on the support of Honduras and Salvador, he proclaimed himself, in February 1885, the supreme military chief of Central America, and claimed the command of all the forces within the five states. President Zaldívar, of Salvador, had been his friend, but after the issue of the decree of union he entered into a defensive alliance with Costa Rica and Nicaragua. In March Barrios invaded Salvador, and on 2nd April a battle was fought, in which the Guatemalan president was killed. He was succeeded as president by General Barillas. No further effort was made to force on the union, and on 16th April the war was formally ended. Peace, however, only provided opportunity for domestic conspiracy, with assassination and revolution in view. In 1892, General Reina Barrios was elected president, and in 1897 he was re-elected; but on 8th February 1898 he was assassinated. Senor Morales, vice-president, succeeded him; but in the same year Don Manuel Estrada Cabrera was elected president for the term ending 1905. With the exception of brief intervals of quarrelling with neighbouring states, Guatemalan activity has been chiefly devoted to political disturbance and insurrection.

Guatemala, or more exactly GUATEMALA LA NUEVA, capital of the Republic, situated in the middle of a broad plain. It lies about 5000 feet above sea-level, and is surrounded on all sides by mountains and volcanoes. It is 75 miles N. of San José, on the Pacific, with which it is connected by railway, and 190 miles S.E. of Puerto Barrios, on the Gulf of Honduras, with which also there is railway communication. In preparation for the exhibition of 1897 much was done to improve the town. The boulevards, which extend to a distance of 3 miles from the city, have undergone extensive repairs, and form a fine carriage drive; a park, La Reforma, has been laid out, and the presidential palace and other public buildings have been erected. The city has suffered somewhat from a fall in the price of coffee, the depression of silver, and other causes, but with the completion of the railway to Puerto Barrios a rapid increase of prosperity is anticipated. The foreign trade is mainly in the hands of Germans. The population in 1893 was 71,525, five-sixths being of European origin.

Guayama, a small town of Porto Rico, the capital of a province of the same name, situated about 10 miles from the south coast. The natural port is Arroyo. It is connected by fine highways with San Juan and Ponce. Population (1899), 5334.

Guayaquil, a city and port of Ecuador, and capital of the province of Guayas. Population (1890), 44,772, of whom 4378 were foreigners; (1900), about 51,000. There is a weekly service of steamers, British and Chilian, north and south, and nineteen-twentieths of the commerce of Ecuador now passes through the port. The following table shows the number of foreign vessels entered and cleared at the port during the years 1896–98:—

	1896.		1897.		1898.	
	Ships.	Tonnage.	Ships.	Tonnage.	Ships.	Tonnage.
Entered .	201	267,931	192	265,208	206	298,805
Cleared .	197	264,240	192	265,208	200	290,855

The value of the exports—chiefly cocoa, coffee, sugar, hides, and fruits—in 1896 was £1,088,919; in 1897, £1,217,628; in 1898, £1,678,170; in 1900, £1,245,531. A railway line runs from Duran on the east bank of the Guayas, opposite Guayaquil, to Chimbo, 60 miles from Duran, and its extension to Quito is now being pushed. After its devastation by fire in 1896 the greater part of the business portion of the city was rebuilt in better style, but on 30th November 1899 a fire broke out in the centre of the city, which in a few hours destroyed some of the most important public buildings, including the theatre, the San José Church, the San Vincente College, and the main offices of the Custom House. A large brewery has been established, and there are cotton and woollen mills, sugar refineries, soap works, chocolate factories, &c. The city is connected with the telegraph cable, and has several tramway lines, electric lighting and telephone service.

Guayra, La, or La Guaira, a town and port of Venezuela, in the province of Caracas, from which it is distant 23 miles by rail; an important port for foreign trade. In 1898, 325 steamships entered the port, 84 of which were British, 39 American, and 70 French. The total shipments of the most valuable exports for the same year were: coffee, 30,256,911 ℔; cacao, 11,466,078 ℔; skins, 89,729 ℔; hides, 2,091,112 ℔; and sabadilla, 171,769 ℔; and in 1899 the weight of coffee shipped was 18,944,000 ℔; of cacao, 11,399,000 ℔; and of hides, 2,155,000 ℔. The total amount of the import duties collected in 1898 was £623,191. One of the most important engineering works in Venezuela is the La Guayra breakwater, built by an English company, over 2000 feet long and 40 feet deep at the extreme point.

Gubbio, a town and bishop's see of the province of Perugia, Umbria, Italy, on the Florence–Ancona line, 68 miles west by south from Ancona by rail. Amongst the public buildings may be mentioned the town hall, containing a museum of pictures, wood-carving of the 15th and 16th centuries, MSS., &c., and the famous Eugubine tables. The manufacture of rose-tinted lustred ware is still pursued with success. Silk-throwing and the making of cement are also carried on. Population (1881), 6290; (1899), 5500.

Guelderland, or Gelderland, formerly a duchy, now a province of the Netherlands. It consists of three very distinct regions. The first, formerly the *Graafschap Zutphen*, lies east of the river Yssel, with diluvial sand and gravel, sloping from east to west (131 to 26 feet), and with its rivers accordingly flowing in the same direction to join the Yssel. The extreme east is occupied by older Tertiary loam, upon which and on the river banks are the most fertile spots, woods, cultivated land, pastures for the cattle bred in the district, towns and villages, with a population of Saxon origin. Farther from the rivers lie heaths, small fens, and sand. The second region, or the *Veluwe* ("bad land"), lies west of the Yssel, is varied by hills (164 to 328 feet), and has a soil of sand and gravel, with clay only along the banks of the Yssel and its feeders. Between the Veluwe hills and the Utrecht ridge the Geldersch valley, formed by the diluvial Rhine, is ill-drained by the Grift into the Zuider Zee. All over the Veluwe are heaths, scantily cultivated (rye and buckwheat), cattle of inferior quality, and sheep, and a sparse population. It is only on grounds sloping to the rivers Yssel and Rhine that large forests have attracted a denser population of mixed origin. The third region, or the *Betuwe* ("good land"), lies south of the Yssel and Rhine, has a level clay soil, varied by isolated hills and a sandy stretch in the direction of Nimeguen. A denser population, mainly of Frankish origin, is occupied in the cultivation of wheat, beetroot, and orchards, the breeding of excellent cattle, shipping, and industrial pursuits. Guelderland is the largest province in the kingdom, having an area of 1906 square miles. Population (1873), 437,778; (1900), 566,649.

Guelph, a city (1879) of Ontario, Canada, 45 miles W. by S. of Toronto, on the river Speed and the Grand Trunk and Canadian Pacific railways. It contains, in addition to the county and municipal buildings, the Ontario Agricultural College. The exports in 1899–1900 were valued at $734,345, imports at $869,280. Population (1881), 9890; (1900), 11,087.

Guernsey. See Channel Islands.

Guerrero, a state of Mexico, bounded on the N. by the states of Mexico and Morelos, on the N.E. by that of Puebla, on the E. and S.E. by Oaxaca, and on the S.W. by the Pacific. Area, 25,003 square miles. Population in 1879, 295,590; and in 1900, 474,594. The state lacks communication facilities, and its territory is mountainous. The principal agricultural products are cereals, coffee, cacao, vanilla, tobacco, textile fibres, &c. These products are valued at about $2,000,000 a year. Gold, silver, mercury, lead, iron, coal, sulphur, &c., are found in the state, but lack of communication retards their working. The capital is Chilpancingo (6312); amongst other towns are Chilapa (8256), Iguala (6631), Tixtla (6588), Acapulco (5770).

Guiana, an extensive region in the north-east of South America, divided between Great Britain, France, Holland, Brazil, and Venezuela. British, French, and Dutch Guiana have certain common physical characteristics. In all three countries different regions must be distinguished: the northern plain, consisting of alluvium deposited by the sea and rivers, 18 to 50 miles in breadth; the gneiss and diabase, forming the beds of the rivers; and the slate formation on the surface, covered in the south by granite. Difference of structure, modified by atmospheric conditions, causes corresponding differences in the surface relief and in vegetation, forming three natural divisions. (1) The flat coast region, with reed-bordered marshes, ridges of shells and sand indicating the former shore lines, and, near the rivers, sand and blue clay or humus. Here plantations have been formed on drained and dyked lands. (2) The higher and drier savannahs, in the east much nearer to the coast than in the west, covered with sand, and overgrown with grass, shrubs, and thin forests. (3) The undulating country rising into forest-covered hills and mountains, as the Tumuc-Humac and Acarai mountains on the southern frontier; the Nassau, Brokopondo, and Mindrineti mountains, respectively near the Maroni and the Surinam and between the latter river and the Saramacca. The character of the

river channels, the rainfall, and tides affect the navigability of the waterways. Generally speaking, in the large rivers flowing south to north vessels of 16 feet draught can ascend with the tide three or four hours' sail from the sea, and vessels drawing 6½ to 9½ feet can ascend still higher in the dry season. The middle stretches up to the rapids or cataracts are navigable for canvas boats.

I. British Guiana, the only British possession in South America, lying between 9° and 1° N. lat. and between 57° and 62° W. long. Its area is over 110,000 square miles, of which only about 130 square miles are under cultivation. Its coast-line from east to west measures 300 miles, while from north to south there is a lineal depth of more than 550 miles. It is bounded on the N. by the Atlantic Ocean, on the E. by Dutch Guiana, on the W. by Venezuela, and on the S. by Brazil. The boundary line between British Guiana and Venezuela was for many years till 1899 the subject of dispute. The Dutch, while British Guiana was in their possession, claimed the whole watershed of the Essequibo river, while the Venezuelans asserted that the Spanish province of Guayana extended up to the Essequibo. In 1886 the British Government declared that it would thenceforward exercise jurisdiction up to and within the boundary (known as the Schomburgk line) suggested by Sir Robert Schomburgk after his survey of 1842–43. In 1897, in consequence of intervention on the part of the United States, arbitration was agreed upon, and two years later the tribunal gave, in Paris, its decision in favour of a line not greatly differing from the Schomburgk line, though it awarded to Venezuela Point Barima and the immediately adjacent land, and the district between the Wenamu and the upper reaches of the Cuyuni. The delimitation of the boundary between British Guiana and Brazil was in 1902 referred to the arbitration of the King of Italy. The physical nature of British Guiana offers, roughly speaking, four different types: first, the seaboard, which, though not swampy, is low, flat, and alluvial; secondly, the basin of the Essequibo river, which traverses the colony from south to due north; thirdly, the savannah, or elevated tableland, averaging 1200 to 1500 feet in height, well watered and treeless; and fourthly, the mountainous portion of the colony, a sandstone group of mountains reaching their highest ascertained summit in Roraima, a remarkable tableland of rock, measuring roughly 4 miles by 8, and rising to a height of 8600 feet above sea-level. The colony is divided into three districts, which take their names from the three principal rivers debouching into the Atlantic—namely, the Demerara, Essequibo, and Berbice, which are navigable for 90, 35, and 150 miles respectively. Other rivers, varying in size and volume from mighty streams to small creeks, intersect the interior. The capital is Georgetown, at the mouth of the Demerara river, with a population of 53,000. New Amsterdam, on the Berbice river, has a population of 8900. Each possesses a mayor and town council, with power to raise local revenues. There are twenty-three villages, with a population of 32,573, the affairs of which are controlled by village councillors. As the climate is not favourable to prolonged physical exertion, and as three days' wage will, as a rule, supply the agricultural labourer's wants for a week, the provision of a trustworthy labour supply for sugar estates is of great importance. For sixty years the labour necessary to carry on the staple industry has been imported under a system of indenture. China helped greatly between 1853 and 1859, and the West Indies and Madeira also contributed, but India has been the only permanent recruiting-ground. A scheme adopted in 1896–97, whereby allotments of lands are made to coolies wishing to remain at the end of their indentures, in lieu of passage back to India, has worked advantageously. The census of 1891 gave a total population of 278,328. In 1899 the population was estimated as follows:—

Europeans, other than Portuguese	4,500
Portuguese	12,200
East Indians	108,000
Chinese	3,800
Africans (born)	3,300
Creoles	116,000
Aboriginal Indians	7,500
Mixed races	31,200
	286,500

English is spoken throughout the colony, but the aboriginal Indians—the Warraus, Arawaks, Wapianas, and Caribs—have their own tribal languages, which are divided into many dialects. Many of these Indians are still wholly uncivilized, although both Roman Catholic and Protestant missionaries have for many generations been working amongst them. The climate is hot, especially from July to October, but not unhealthy. The temperature ranges from 78° to 88°. The rainfall ranges from 75 to 130 inches per annum; earthquakes and violent thunderstorms are of rare occurrence, and the colony is not within the region of hurricanes. Sugar, the cultivation of which is confined to the fringe of the coast lands and to the lower banks of the main rivers, for many years the principal product of British Guiana, has survived, in the face of bounties and other adverse conditions, better than in any other West Indian colony. Attention has, however, latterly been paid to other products, especially to rice, cacao, and kola. Though the lower parts of the upper reaches of the rivers are not very fertile, there are between the true coast lands and the ranges of sand dunes which occur in Berbice, Demerara, and Essequibo, at varying distances from the mouths of the rivers, great tracts of land of marked fertility formed by the deposition of the sea-borne mud of the Amazon, which will produce almost any tropical vegetable and fruit. The timber industry is limited to those regions which lie near the lower stretches of the principal rivers, overland transport of heavy logs being difficult and costly, while on the upper reaches of the rivers are many cataracts and falls. Unalienated Crown lands extend to about 80,000 square miles, largely covered by virgin forest and in need of drainage. This land can be purchased at very cheap rates. Without beneficial occupation, however, the land reverts to the Crown. Licenses to cut timber, to collect ballata gum, indiarubber, &c., and for quarrying, are granted. The gold-producing districts (mainly placer workings) are situated in the forest portion of the colony, *i.e.*, Berbice and Corentyn; Demerara and Essequibo rivers, Mazaruni and Puruni rivers; Cuyuni river and Groote Creek, Essequibo river; and Barima, Barama, and Waini rivers. The revival of the industry dates from 1884. Diamonds to the value of £11,210 were exported in 1901, almost all from the Mazaruni district.

During 1900–1, 94,745 tons of sugar (valued at £1,082,400) were exported, besides 4,023,828 gallons of rum (value, £287,400), and gold £377,400, the other exports being molasses, timber, ballata gum, shingles, cattle, and hides. In 1878 the value of the imports was £2,150,714; that of 1900–1 was £1,311,800. In 1878 the value of the exports was £2,507,571; that of 1900–1 was £1,577,400. The average value of the imports in the five years ending 1901 was £1,288,000, as compared with an average of £1,838,400 in the five years 1881–85 inclusive; the averages of the exports for the corresponding periods being £1,815,400 and £2,515,400 respectively. The following shows the direction of the import trade in 1900–1:—United Kingdom, 48·4 per cent.; British possessions, 13·7; Foreign countries, including the United States (£759,100 in 1899–1900), 31·7. In 1878 the revenue was £405,092; in 1898–99 it was £525,865. In 1878 the

expenditure was £417,995; in 1898–99 it was £525,387. The public debt in 1877 was £323,563; in 1899 it was £975,791. During 1897–98 the tonnage of vessels entering was 304,428 (steam, 242,571; sailing, 61,857), and cleared 316,770 (steam, 253,960; sailing, 62,810). After the United Kingdom, Holland sends the most vessels; then Norway and France. Queen's College, Georgetown, a Government institution, provides secondary education for about 100 boys (mainly English or Creole, but including a fair number of Portuguese, Chinese, East Indian, and others). Secondary teaching for girls is provided at private establishments—Roman Catholic and Wesleyan. The matriculation and other examinations of the University of London and the Cambridge Local Examinations are held in the colony. A scholarship is awarded annually of £200 per annum for three years, or, for medical students, £150 for five years. In 1898–99 there were 210 state-aided elementary schools under the management of ministers of religion, with 28,689 children on the books, and an average daily attendance of 15,959. Except those belonging to estates, these schools are denominational as follows:—Anglican, 72; Church of Scotland, 36; Congregational, 30; Wesleyan, 29; Roman Catholic, 27; Estate, 13; Moravian, 2; Lutheran, 1. Four Government primary scholarships are given yearly. The bishopric of British Guiana forms part of the West Indian Province of the Church of England.

There are no imperial troops now stationed in the colony. The police, semi-military in character, numbers 806 officers and men, with a rural constabulary numbering 1169. The militia numbers 426, with a reserve of 196. There are 5 public hospitals and lunatic and leper asylums; 69 post-offices (39 being telegraph stations), and 1157 miles of telegraph lines. There are two lines of railway: from Georgetown to Mahaica (20 miles); from Demerara river to Essequibo river (18½ miles). The total length of roads in the colony is 264 miles (of which 163 were constructed by Government, and 101 by the proprietors of sugar estates).

The political constitution of the colony is, from a theoretical point of view, a mixture of a Crown colony, a dependency, and an autonomous colony—due to the fact that when Great Britain acquired the colony from the Dutch in 1814 she adopted the Dutch-Roman law bequeathed by Holland, which is still in force in civil cases, modified by Orders in Council and local ordinances; the criminal law being based on that of England. The Government consists of the governor and the court of policy, which comprises 15 members, 7 *ex-officio* nominated, and 8 elected. The court acts as a legislative council except for purposes of taxation, which is settled by the "combined court," consisting of the court of policy and 6 elected financial representatives. There is also an executive council, consisting of the governor, 5 official and 3 unofficial members nominated by the Crown, which discharges administrative functions, which until 1891 belonged to the court of policy.

(F. CU.)

II. DUTCH GUIANA, or SURINAM, has an area of about 57,900 square miles. The interest taken by the Netherlands in the colony greatly increased during the last twenty years of the 19th century, as shown by the establishment of the Surinam Association, of the Steam Navigation Company's service to Paramaribo, and by the formation of a botanical garden for experimental cultures at that town, as also by geological and other scientific expeditions, and the exhibition at Haarlem, 1898. The most important crops and those supplying the chief exports are cocoa, yielding, in 1899, 9,733,900 lb, coffee 893,100 lb, and sugar, all cultivated on the larger plantations, with rice, maize, and bananas on the smaller or coast lands. The area under sugar in 1899 was 4243 acres, under cocoa 33,536 acres, other cultures 3669 acres; total, 41,448 acres. Most of the larger plantations are situated on the lower courses of the Surinam, Commewyne, Nickerie, and Cottica, and on the coast lands, rarely in the upper parts. The goldfields lie in the older rocks (especially the slate) of the upper Surinam, Saramacca, and Maroni, and near these rivers mining concessions had been granted of 968,155 acres in 1899. The production of gold in 1899 amounted to 893,197 grammes, valued at £101,970. Cattle-rearing is a very inconsiderable industry, the total live stock of the colony in 1899 being represented by about 6760 cattle and horses, 600 asses and mules, 181 sheep, 1726 goats, and 2627 swine.

During late years meteorological observations have been carried on at five stations (Paramaribo, Burnside (Coronie), Sommelsdijk, Nieuw-Nickerie, and Groningen). The mean range of temperature for the day, month, and year shows little variation, being respectively 77·54°–88·38° F., 76·1°–78·62° F., and 70·52°–90·14° F. The north-east trade winds prevail throughout the year, but the rainfall varies considerably; for December and January the mean is respectively 8·58 and 9·57 inches, for May and June 11·26 and 10·31 inches, but for February and March 7·2 and 6·81 inches, and for September 2·48 and 2·0 inches. The seasons comprise a long and a short dry season, and a period of heavy and of slight rainfall. The inhabitants of Surinam differ with the soil and the products. The Indians (Caribs, Arawaks, Warrous) live on the savannahs, or on the upper Nickerie, Coppename, and Maroni, far from the plantations, cultivating their fields of manioc or cassava, and for the rest living by fishing and hunting. They number 1000 to 2000. The bush negroes (Marrons) dwell between 3° and 4° N., near the isles and cataracts. They are estimated at 8000, and are employed in the transport of men and goods to the goldfields, the navigation of the rivers, in trade with the Indians, and in the transport of wood to Paramaribo and the plantations. The inhabitants of Paramaribo and the plantations comprise a variety of races, represented by 400 Chinese, 600 Javanese, 10,000 coolies from India and the West Indies, 30,000 to 40,000 negroes, and 2000 of the white race; Jews number about 1200, and there is a floating Dutch population of 600. The total (1899) is about 67,150, of whom nearly one-half are in Paramaribo and one-half in the districts. In 1852 there were 6000 persons in the town and 32,000 in the districts; thus, while the population has increased but little during fifty years, the movement from the districts to the town has increased. During the same period the number of immigrants was 29,570. Agriculture is the chief means of subsistence. Of 30,000 persons whose occupation was given in the statistics, close upon 21,000 were engaged in agriculture or on the plantations, 2400 in gold-mining, and only 1000 in trade. The exports increased in value from £200,800 in 1875 to £459,800 in 1899, and the export of gold between 1882 and 1899 from £65,350 to £99,600. The imports increased from £260,450 in 1875 to £510,180 in 1899. The growth of the commerce and the countries with which it is chiefly carried on are shown in the following table:—

Year.	Vessels.			Tonnage.			Value in thousands of £.		
	Netherlands.	United States.	Other Countries.	Netherlands.	United States.	Other Countries.	Netherlands.	United States.	Other Countries.
				Imports.					
1883	30	21	198	5,944	5800	39,410	173	84	173
1899	27	14	190	27,752	7641	100,209	267	111	132
				Exports.					
1883	15	21	214	3,180	5462	42,328	69	104	165
1899	27	8	197	27,137	3578	106,935	147	267	45

According to statistics compiled by ex-governor Asch van Wyck, the population in 1898 comprised 29,000 Moravian Brethren, 9000 Protestants, 16,750 Roman Catholics, 1250 Jews, 2700 Mahommedans, and 9700 Hindus. As regards instruction, Paramaribo had in 1899 six government primary schools with 53 teachers and 1612 pupils, besides eighteen private schools with 75 teachers and 3876 pupils. In the districts there were thirteen government schools with 14 teachers and 693 pupils, and sixteen private schools with 21 teachers and 959 pupils.

(C. M. K.)

III. FRENCH GUIANA.—This colony is situated between Dutch Guiana and Brazil. A delimitation of the territory belonging to France and the Netherlands was arrived at in 1891, by decision of the Emperor of Russia. In December 1900 the Swiss Government fixed as the boundary between French Guiana and Brazil the river Oyapok and the watershed on the Tumuc Humac mountains, thus awarding to France about 3000 of the 100,000

square miles which she claimed. French Guiana, according to the most recent official estimate, has an area of 50,030 square miles; but a strange divergence of opinion exists upon this point, and competent authorities variously place it, without the zone whose possession was till recently disputed with Brazil, at 47,000 square miles and 58,000 square miles. M. Coudreau ventured across the immense inland tropical forest in 1887–91, but it is still little known. The population has little altered in numbers, being estimated at about 30,000 in 1898. Of this total 12,350 lived at Cayenne, 10,100 were in the communes, 5700 formed the penal population, 1500 were native Indians (Galibi, Emerillon, Oyampi), and 500 near Maroni were negroes. Apart from Cayenne, which was rebuilt after the great fire of 1888, the centres of population are unimportant: Sinnamary with 1500 inhabitants, Mana with 1750, Roura with 1200, and Approuague with 1150. In 1892 French Guiana was finally divided into fourteen communes, exclusive of the Maroni district. Belonging to the colony are also the three Safety Islands (Royale, Joseph, and Du Diable—the last notable as the island where Dreyfus was imprisoned), the Enfant Perdu Island, and the five Remire Islands. The colony is administered by a governor, assisted by a director of the interior, a chief of the judicial service, a director of the penitentiary administration, and by a privy council. In 1879 an elective general council of sixteen members was constituted. There are a tribunal of first instance and a higher tribunal at Cayenne, besides four justices of peace, one of whom has extensive jurisdiction in other places. White convicts are now sent to the settlements; in 1885 French Guiana was appointed as a place of banishment for confirmed criminals and for convicts sentenced to more than eight years' hard labour. Of the £207,000 demanded for the colony in the colonial budget for 1901, £195,000 represented the estimated expenditure on the penal settlement, so that the cost of the colony was only about £12,000. The local budget for 1901 balanced at £99,000. Instruction is given in the college of Cayenne and in six primary schools. At the head of the clergy is an apostolic prefect. The armed force consists of two companies of marine infantry, half a battery of artillery, and a detachment of gendarmerie, and comprises about 380 men. A very small portion of the territory is devoted to agriculture, although France has paid some attention to the development of this branch of activity. In 1880 a colonial garden was created near Cayenne; since 1894 an experimental garden has been laid out at Baduel. About 8200 acres are cultivated, of which 5400 acres are under cereals and rice, the remainder being under coffee, cacao, cane, and other cultures. The low lands between Cayenne and Oyapok are capable of bearing colonial produce, and the savannahs from the Oyapok to the Arajovary might support large herds; cereals, root-crops, and vegetables might easily be grown on the high grounds, and the working of the timber in the forests of the interior should be profitable. As regards gold-mining, placers of very great wealth have been discovered on the Awa, on the Dutch frontier, and at Carsevenne in the territory which formed the subject of the Franco-Brazilian dispute. The production amounted to £160,000 in 1889, £280,000 in 1892, and to nearly £320,000 in 1899. But wages are high and transport is costly. Silver and iron have been found in various districts; kaolin is extracted in the plains of Montsinéry; and phosphates have been discovered at several places. Besides 123 workings for gold, the industries of French Guiana comprise saw-mills, distilleries, brick-works, and sugar-works. The commerce in 1885 amounted to £336,000 for imports, and to £144,000 for exports; in 1897 the values were respectively £373,350 and £286,400. The share of France and her colonies in the exports was £277,400, and in the imports £253,500. For 1899 imports were valued at £421,000, exports at £270,000. The gold export amounted to £255,000. The imports consist of wines, flour, clothes, &c. The shipping during 1899 numbered 150 vessels of 40,300 tons (metric) entered, and 149 of 39,500 tons cleared. Cayenne is almost the only port. One of the drawbacks to the development of the colony is the lack of labour. Native labour is most difficult to obtain, and attempts to utilize convict labour have not proved very successful. So far also every effort to supply the need by immigration has proved a failure. The land routes are not numerous. The most important are that from Cayenne to Iracoubo (78 miles), and that from Cayenne to Kaw along the coast to the mouth of the Approuague. Towards the interior there are only foot-paths, badly made. By water, Cayenne is in regular communication with the Safety Islands (35 miles), and the mouth of the Maroni (80 miles), with Fort de France in the island of Martinique, where travellers meet the mail packet for France, and with Boston (United States). There is a French cable between Cayenne and Brest.

See VIALA. *Les Trois Guyanes.* Montpellier, 1893.—LEVASSEUR. *La France*, tome ii. Paris, 1893. (P. L.)

Guildford, a municipal borough, market-town, and county town of Surrey, England, in the Guildford parliamentary division (since 1885) of the county, on the Wey, 30 miles south-west of London by rail. It is the seat of a suffragan bishopric. Guildford Castle has been purchased by the corporation, and the ground about it opened as a public garden (1888). Public baths, a cattle market, and an isolation hospital have been erected, and the Royal Surrey Hospital has been enlarged. Area, 607 acres. Population (1881), 11,288; (1901), 15,937.

Guimarães, a town of Portugal, district Braga, 25 miles S.E. of Braga. It has one of the largest markets in the kingdom, and manufactures cutlery, linen, leather, and preserved fruits. The vineyards cover about 9000 acres. Population (1900), 8863.

Guinea, French, a French colony in West Africa, bounded on the W. by the Atlantic, on the N. by Portuguese Guinea and Senegal, on the E. by Senegal and the Ivory Coast, and on the S. by Liberia and Sierra Leone. The shore, which extends from the Alcatraz Islands on the north to the Scarcies Islands on the south, is low, monotonous, and bordered with sand-dunes. The islands of Tomba, Laos, Matakong are at various distances from the coast. The protectorate of Futa Jallon, which commences at a distance of 80 miles from the sea, is high, and possesses well-marked features; some places have an altitude of 4000 feet, and there is scarcely any more important hydrographic centre in Africa. French Guinea is watered by the Cogon, the Rio Nunez (70 miles), the Rio Pongo, and the Mellacoree; from the Futa Jallon flow the Gambia, the Faleme, the Bafing, and the Niger. Futa Jallon was annexed after the expeditions of Moustier and Zweifel (1879), Bayol (1881), and Plat (1888). There has never been any difficulty in occupying this region. French Guinea was administered by the governor of Senegal till 1893, when the colony was declared a separate administrative unit. The present limits of the hinterland were fixed by the decree of October 1899, dividing the French Sudan (see SUDAN) among the four French West African colonies, by which French Guinea received the six circles Dinguiray, Siguiri, Kurussa, Kankan, Kissandugu, Beyla, and nearly doubled its area, which is now estimated at 92,000 square miles. The population on this area numbers about 1,250,000. The

colony is administered by a governor (since 1895 under the governor-general of French West Africa), assisted by a council composed of three official and three civil members. One of the three French colonies allowed to manage their own finances, French Guinea is practically self-supporting. In 1898 the local expenditure was only £53,805 as compared with a revenue of £70,763, and in 1899, though there was a subsidy from the home Government of £12,700, about £4500 of this was voted for military expenditure and £4000 for a road to the Niger. The inhabitants do not cultivate more than one-tenth of the surface of the country. Cotton textiles are by far the most important import; in 1898 their value amounted to £153,800 out of a total of £360,800, in 1899 to £253,000 out of a total of £617,700 (including £77,000 specie). The other principal items in 1899 were hardware £36,800, and rice £31,500. Great Britain and Sierra Leone supply practically all the textiles, and have a commanding share in the other imports. The proportionate share of France itself is small, but increasing: £59,400 in 1898, £165,000 in 1899. Rubber predominates even more among the exports than textiles among the imports, being valued in 1898 at £237,600 out of a total value of exports of £312,000, and in 1899 at £280,000 out of a total of £378,500. Though a source of great prosperity to the colony, the consequences of the supply of rubber coming to an end through abusive exportation are already beginning to be discussed. Of other exports, that of cattle from Futa Jallon is important; this has had to be curtailed for fear of exhausting the supply. Futa Jallon is also rich in gold. There is thought to be a promising future for the export of groundnuts and wax. Great Britain and Sierra Leone receive most of the exports, but France's share increased from £22,000 in 1898 to £38,500 in 1899. Means of communication are difficult. A railway will connect Konakry with Kurussa on the Niger, so as to bring the produce of the Sudan to the coast. The inland system of telegraphs was united in 1899 with that of Senegal by a line which brought the total length laid down in three years up to 560 miles. There is telegraphic communication with Europe along an English submarine cable, and steamers call at Konakry from Havre, Bordeaux, and Marseilles, and Liverpool, Antwerp, and Hamburg. The Belgian line has transferred its headquarters to Konakry from Sierra Leone, which, indeed, has in other directions lately lost much of its trade to its French neighbour. In 1898, 2369 vessels of 263,763 tons entered Konakry, and 2286 of 263,127 tons cleared. The centres of population are Konakry, the capital, on the isle of Tomba, Boké on the Rio Nunez, Dubreka, Beuti, and Timbo in Futa Jallon.

Guinea, Portuguese, a colonial province of Portugal, on the west coast of Africa, between 11° 40′ and 12° 40′ N. and 13° 40′ W. and the Atlantic, with an area of 4394 square miles, and an estimated population of 67,165. It is on the whole a flat region, traversed by an extensive network of rivers, of which the chief are—the Cacheo, navigable to Farim, 105 miles; the Mansoã, navigable for 44 miles; the Geba; the Corubal; the Grande de Guinala, virtually an inlet of the sea; the Combidian; and the Cacine. It includes the neighbouring archipelago of Bissagos. The rainy season lasts from May to November, and is very hot (89·6° F.) and tempestuous. Rice and millet are the principal cultivated crops. The natural products of the soil embrace *mancarra* (almonds), indiarubber, tobacco, kola nuts, indigo, cotton, coffee, and palm oil; and of the forests, mahogany, ebony, calabash, and other trees. The total trade (imports and exports) has increased from £111,100 in 1894 to £356,670 in 1899; the shipping which entered has likewise increased from 745 vessels of 47,978 tons in 1894 to 1294 vessels of 64,756 tons in 1899. The capital is Bolama, on the island of the same name in the Bissagos Archipelago, opposite the estuary of the Grande; but the principal port is Bissao, on the island of the same name. The native inhabitants belong chiefly to the Fulah, Mandingo, and Biafada races. The province is administered by a governor, assisted by a council. The estimated revenue for 1900–1901 was £23,780, and the expenditure £40,670.

See E. DE VASCONCELLOS, *As Colonias Portuguesas.* Lisbon, 1896-97. (E. DE V.)

Guines, a town in the interior of Havana province, Cuba. It is in the midst of a rich sugar district. Population (1899), 8149.

Guipuzcoa, a maritime province of Northern Spain, with an area of only 728 square miles, divided into four administrative districts and ninety parishes. The population was 181,856 in 1887, and 191,822 in 1897, being then surpassed in density only by the provinces of Barcelona and Pontevedra. Of the births 3·42 per cent. were illegitimate. The province loses large numbers through emigration. The main line of the northern railway from Madrid to France runs through the province for 90 miles, passing one of the most important custom-houses of Spain. This province has 350 miles of first-class roads, kept up at local expense only. It is very rich in mineral springs, having no fewer than two salt, twenty-two sulphurous, and thirty-five ferruginous, much frequented every summer by people from all parts of Spain. The fishing fleet is composed of 350 sailing boats and some small steamers, manned by 1900 men and boys, who secure £80,000 worth of fish annually. The coasting trade exceeds £400,000 a year, and by Irun, Passages, and the frontier roads £4,000,000 of imports and £3,000,000 of exports pass to and from France, partly in transit for the rest of Europe. Apart from the four Catalan provinces, no province has witnessed such a development of local industries as Guipuzcoa. The principal industrial centres are Irun, Renteria, Villabona, Vergara, and Azpeitia for cotton and linen stuffs; Zumarraga for osier; Eybar, Plasencia, and Elgoibar for arms and cannon, and gold incrustations; Irun for soap and carriages; San Sebastian, Irun, and Onate for paper, glass, chemicals, and saw-mills; Tolosa for paper, timber, cloths, and furniture; and the banks of the bay of Passages for the manufacture of liqueurs of every kind, and the preparation of wines for export and for consumption in the interior of Spain. This last industry occupies several thousand French and Spanish workmen. There are only nineteen productive mines, from which the main outputs in 1898 were 20,582 tons of iron and 20,659 tons of lignite; and of hydraulic cement 79,064 tons were manufactured. The mines and works connected therewith gave employment to 1300 hands. In 1898 the live stock included 1937 horses, 254 mules, 5492 asses, 60,655 cattle, 119,444 sheep, 1378 goats, 16,840 pigs. Oxen are much used as draught animals on the steep roads of the mountains. Wheat occupied 30,690 acres, and 31,000 were given to beans.

Guiraud, Ernest (1837–1892), French composer, was born at New Orleans on 26th June 1837. He studied at the Paris Conservatoire, where he won the "Grand Prix de Rome." His father had gained the

same distinction many years previously. The fact is worthy of note, as it affords the only instance of both father and son obtaining this much-coveted prize. Ernest Guiraud is the composer of the following operas :—*Sylvie* (1864), *Le Kobold* (1870), *Madame Turlupin* (1872), *Piccolino* (1876), *Galante Aventure* (1882); also the ballet *Gretna Green*, given at the Opéra in 1873. His opera *Frédégonde* was left in an unfinished condition and terminated by Saint-Saens. It was produced at the Paris Opéra in 1895. Guiraud, who was a fellow student and intimate friend of Georges Bizet, was for some years professor of composition at the Conservatoire. He was the author of an excellent treatise on Instrumentation. His music, if not particularly individual, is characteristically French, and is invariably scored with consummate art. He died in Paris, 6th May 1892.

Gujranwala, a town and district of British India, in the Rawalpindi division of the Punjab. The town is situated 40 miles N. of Lahore by rail. The population in 1881 was 22,884, in 1891 it was 26,785; the municipal income in 1897–98 was Rs.68,799. There are manufactures of brass-ware, jewellery, silk and cotton scarves. The DISTRICT comprises an area of 3017 square miles. The population in 1881 was 616,892, and in 1891 was 690,169, giving an average density of 229 persons per square mile. In 1901 the population was 756,749, showing an increase of 10 per cent. The land revenue and rates were Rs.10,95,970, the incidence of assessment being R.1–9–9 per acre; the cultivated area in 1896–97 was 675,169 acres, of which 557,452 were irrigated, including 230,685 from government canals. Part of the upland tract has been brought under cultivation by the Chenab canal. The number of police was 503; the number of schools in 1896–97 was 320, with 10,137 pupils, the proportion of boys at school to the male population of school-going age being 15·8 per cent.; the registered death-rate in 1897 was 27·89 per thousand. There are three printing-presses, issuing one vernacular newspaper, and two factories for pressing cotton. There are 116 miles of railway in all, 82 miles of navigable river, and 64 miles of metalled roads.

Gujrat, a town and district of British India, in the Rawalpindi division of the Punjab. The town stands about 5 miles from the right bank of the river Chenab, and about 70 miles N. of Lahore by rail. The population in 1891 was 18,050; the municipal income in 1897–98 was Rs.31,104. It has manufactures of inlaid work in gold and iron, brass-ware, boots, cotton goods, and shawls, and also one printing-press. The DISTRICT comprises an area of 2051 square miles. The population in 1881 was 689,115, and in 1891 was 760,875, giving an average density of 371 persons per square mile. In 1901 the population was 752,038, showing a decrease of 1 per cent., compared with an increase of 10 per cent. in the previous decade. The land revenue and rates were Rs.7,66,520, the incidence of assessment being R.1–2–9 per acre; the cultivated area in 1896–97 was 533,498 acres, of which 184,128 were irrigated, entirely from private wells; the number of police was 520; the number of schools in 1896–97 was 413, with 12,880 pupils, the proportion of boys at school to the male population of school-going age being 17·6 per cent., the highest figure in the province; the registered death-rate in 1897 was 21·89 per thousand. There are 76 miles of railway in all, 72 miles of navigable river, and 55 miles of metalled roads, but no government canal.

Gull, Sir William Withey, BART. (1816–1890), English physician, was the youngest son of John Gull, a bargeowner and wharfinger of Thorpe-le-Soken, Essex, and was born on 31st December 1816. He began life as a schoolmaster, but in 1837 Benjamin Harrison, the treasurer of Guy's Hospital, who had noticed his ability, brought him up to London from the school at Lewes where he was usher, and gave him employment at the hospital, where he also gained permission to attend the lectures. In 1838 he matriculated at the University of London, and graduated M.B. in 1841. Two years later he was made a lecturer in the medical school of the hospital, in 1851 he was chosen an assistant physician, and in 1858 he became full physician. In 1847 he was elected Fullerian professor of physiology in the Royal Institution, retaining the post for the usual three years, and in 1848 he delivered the Gulstonian Lectures, taking for his subject paralysis, the disease of which he afterwards died. At the College of Physicians he filled every office of honour but that of president. He died in London on 29th January 1890 after a series of paralytic shocks, the first of which had occurred nearly three years previously. He was created a baronet in 1872, in recognition of the skill and care he had shown in attending the Prince of Wales during his attack of typhoid in 1871. Sir William Gull's fame rested mainly on his success as a clinical practitioner; as he said himself, he was "a clinical physician or nothing." This success must be largely ascribed to his remarkable powers of observation, and to the great opportunities he enjoyed for gaining experience of disease. He was sometimes accused of being a disbeliever in drugs. That was not the case, for he prescribed drugs like other physicians when he considered them likely to be beneficial. He felt, however, that their administration was only a part of the physician's duties, and his mental honesty and outspokenness prevented him from deluding either himself or his patients with unwarranted notions of what they can do. But though he regarded medicine as primarily an art for the relief of physical suffering, he was far from disregarding the scientific side of his profession, and he made some real contributions to medical science. His papers, which were not very numerous, were printed chiefly in *Guy's Hospital Reports* and in the proceedings of learned societies: among the subjects he wrote about were cholera, rheumatic fever, tænia, paraplegia, and abscess of the brain, while he distinguished for the first time the disease now known as myxœdema, describing it as a "cretinoid condition in adult women."

Gulpáïgán, a district and city in Central Persia, situated north-west of Isfahán and south-east of Irák. Together with Khunsár it forms a small province, paying a yearly revenue of about £6000. The city of Gulpáïgán is situated 87 miles N.W. of Isfahán, at an elevation of 5875 feet, in 33° 24′ N. lat. and 50° 20′ E. long., and has a population of about 5000. The district is fertile, and produces much grain and some opium. Sometimes it is under the governor-general of the Isfahán province, at others it forms part of the province of Irák, and at times it is under a governor appointed from Tehran. It was in 1902 part of Irák.

Gumuljina, a town of European Turkey, in the vilayet of Adrianople. It is situated on the river Karaja, south of the eastern extremity of the Rhodope range of mountains and north-east of the Gulf of Lagos, and is a station on the railway between Salonica and Dedé-Agach. It has a population of about 20,000, of whom three-fourths are Turks, and the remainder Greeks, Jews, and Armenians. The district produces hard wheat, equal in quality to that of Taganrog, maize, barley, and tobacco. Sericulture and viticulture are both practised on a limited scale. The wine of Gumuljina is everywhere highly

esteemed. The most prominent feature in the commercial life of the place is its cattle fair, held annually on Greek Palm Sunday.

Gümüsh-Khaneh, the chief town of a sanjak of the same name (area, 2365 square miles; population, 114,800) in the Trebizond viláyet of Asiatic Turkey, altitude 4400 feet, situated on high ground in the valley of the Kharshut Su, about half a mile from the Trebizond–Erzerúm *chaussée*. The silver mines from which the place takes its name were noted in ancient times, and are mentioned by Marco Polo. The population of the town is 3000, chiefly Greeks.

Gun.—Firearms are said to have been first used in European warfare in the 14th century. The hand gun came into practical use in 1446, and was of very rude construction. It consisted of a simple iron or brass tube with a touch-hole at the top fixed in a straight stock of wood, the end of which passed under the right armpit when the "gonne" was about to be fired. A similar weapon was also used by the horse-soldier, with a ring at the end of the stock, by which it was suspended by a cord round the neck; a forked rest, fitted by a ring to the saddlebow, served to steady the gun. This rest, when not in use, hung down in front of the right leg. A match made of cotton or hemp spun slack, and boiled in a strong solution of saltpetre, or in the lees of wine, was an appurtenance of the hand gun. The touch-hole was first placed on the top of the barrel, but afterwards at the side, with a small pan underneath to hold the priming, and guarded by a cover moving on a pivot.

An improvement in firearms took place in the first year of the reign of Henry VII., or at the close of Edward IV., by fixing a cock on the hand gun to hold the match, which was brought down to the priming by a trigger, whence the term matchlock or *arc-à-bouche*, a bow with a mouth, subsequently corrupted to *harquebus*. The harquebus or matchlock was supposed to have been invented in Italy. This weapon is still in use among the Chinese, Tartars, Sikhs, Persians, and Turks. An improvement in the stock was also made during this period by forming it with a wide butt end to be placed against the right breast. Subsequently the stock was bent, a German invention, and the arm was called a hackbutt or hagbut, and the smaller variety a demihague. The harquebus and hackbutt were about a yard in length, including barrel and stock, and the demihague was about half the size and weight, the forerunner of the pistol. The wheel-lock, an improvement on the matchlock, was invented in Nuremberg in 1517; was first used at the siege of Parma in 1521; was brought to England in 1530, and continued in partial use there until the time of Charles II. This wheel-lock consisted of a fluted or grooved steel wheel which protruded into the priming pan, and was connected with a strong spring. The cock, also regulated by a spring, was fitted with a piece of pyrites (sulphuret of iron). In order to discharge the gun the lock was wound up by a key, the cock was let down on the priming pan, the pyrites resting on the wheel; on the trigger being pressed the wheel was released and rapidly revolved, emitting sparks, which ignited the powder in the pan. The complicated and expensive nature of this lock, with its liability to injury, no doubt prevented its general adoption.

About 1540 the Spaniards constructed a larger and heavier firearm, carrying a ball of 10 to the pound, called a musket. This weapon was introduced into England before the middle of the 16th century, and came into general use throughout Europe, having been first extensively used at the battle of Pavia in 1525. The snaphaunce was invented about this period in Germany, and from its comparative cheapness was much used in England, France, and Holland. It held a flint instead of the pyrites of the wheel or firelock, which ignited the powder in the pan by striking on a piece of furrowed steel, when released by the trigger, and emitting sparks.

As a sporting weapon the gun may be said to date from the invention of the wheel-lock in the beginning of the 16th century, though firearms were used for sporting purposes in Italy, Spain, Germany, and to some extent in France, in the 15th century. Before that period the longbow in England and the crossbow on the Continent were the usual weapons of the chase. In Great Britain little use appears to have been made of firearms for game shooting until the latter half of the 17th century, and the arms then used for the purpose were entirely of foreign make.

The French gunmakers of St Étienne claim for their town that it is the oldest centre of the firearms industry. They do not appear to have made more than the barrels of the finest sporting arms, and these even were sometimes made in Paris. The production of firearms by the artists of Paris reached its zenith about the middle of the 17th century. The Italian, German, Spanish, and Russian gunsmiths also showed great skill in the elegance and design of their firearms, the Spaniards in particular being makers of fine barrels. Pistols are understood to have been made for the first time about 1540 at Pistoia in Italy, from which town they receive their name. About 1635 the modern firelock or flint-lock was invented, which only differed from the snaphaunce by the cover of the pan forming part of the furrowed steel struck by the flint. Originally the priming was put into the pan from a flask containing a fine-grained powder called serpentine powder. Later the top of the cartridge was bitten off, and the pan filled therefrom before loading. The mechanism of the flint-lock musket rendered all this unnecessary, as, in loading, a portion of the charge passed through the vent into the pan, where it was held by the cover or hammer. The highest development of the flint-lock is found in the fowling-pieces of the end of the 18th and beginning of the 19th centuries, particularly those made by Joseph Manton, the celebrated English gunsmith and inventor. The Napoleonic wars afforded English gunmakers an opportunity, which they fully utilized, of gaining the supremacy over their foreign competitors in the gunmaking trade. English gunmakers reduced the weight, improved the shooting powers, and perfected the lock mechanism of the sporting gun, and increased the range and efficiency of the rifle. This transference of the gunmaking craft from the Continent to England was also assisted by the tyranny of the foreign gunmaking guilds. In 1637 the London gunmakers obtained their Charter of Incorporation. The important gunmaking industry of Birmingham dates from 1603, and soon rivalled that of London. Double shot-guns do not appear to have been generally used until the 19th century. The first successful double guns were built with the barrels over and under, and not side by side, and were invented about 1616 by one Guilliano Bossi of Rome. In 1784 double shot guns were described as a novelty. Joseph Manton patented the elevated rib which rested on the barrels. The general success of the double gun was eventually due to the light weight which the better material and workmanship of the best gunmakers made possible, and to the quickness and certainty of ignition of the modern cartridge.

The objections to the flint-lock were that it did not entirely preserve the priming from wet, and that the flint sparks sometimes failed to ignite the charge. In 1807

the Rev. Mr Forsyth obtained a patent for priming with a fulminating powder made of chlorate of potash, sulphur, and charcoal, which exploded by concussion. This important improvement in firearms was not recognized and adopted by the military authorities until more than thirty years later. In the meantime it was gradually developed, and the copper percussion cap invented, by various gunmakers and private individuals. Thomas Shaw of Philadelphia first used fulminate in a steel cap in 1814, which he changed to a copper cap in 1816. It was not until the introduction of the copper cap that the percussion gun could be considered in every way superior to the flint. In 1834, in the reign of William IV., Forsyth's invention was tested at Woolwich by firing 6000 rounds from six flint-lock muskets, and a similar number from six percussion muskets, in all weathers. This trial established the percussion principle. The shooting was found to be more accurate, the recoil less, the charge of powder having been reduced from 6 to 4½ drs., the rapidity of firing greater, and the number of miss-fires much reduced, being as 1 to 26 nearly in favour of the percussion system. In consequence of this successful trial the military flintlock in 1839 was altered to suit the percussion principle. This was easily accomplished by replacing the hammer and pan by a nipple with a hole through its centre to the vent or touch-hole, and by replacing the cock which held the flint by a smaller cock or hammer with a hollow to fit on the nipple when released by the trigger. On the nipple was placed the copper cap containing the detonating composition, now made of three parts of chlorate of potash, two of fulminate of mercury, and one of powdered glass.

In 1840 the Austrian army was supplied with the percussion musket, and in 1842 a new model percussion musket with a block or back-sight for 150 yards was issued to the British army, 11 ℔ 6 ozs. in weight, 4 ft. 6¾ in. in length without bayonet, 6 ft. with bayonet, and with a barrel 3 ft. 3 in. in length, firing a bullet of 14½ to the ℔ with 4½ drs. of powder. This musket was larger in bore than that of France, Belgium, Russia, and Austria, and thus had the advantage of being able to fire their balls, while the English balls could not be fired from their barrels. But the greater weight and momentum of the English ball was counteracted by the excess of windage. This percussion musket of 1842, the latest development of the renowned Brown Bess, continued in use in the British army until partially superseded in 1851 by the Minié rifle, and altogether by the Enfield rifle in 1855. (For further information as to the history and development of military, target, and sporting rifles see RIFLE.)

Modern Shot Guns.—The modern sporting breech-loaders may be said to have originated with the invention of the cartridge-case containing its own means of ignition. The breech-loading mechanism antedated the cartridge by many years, the earliest breech-loading hand guns dating back to 1537. Another distinct type of breech-loader was invented in France about the middle of the 17th century. During the 17th and 18th centuries breech-loading arms were very numerous and of considerable variety. The original cartridge, a charge of powder and bullet in a paper envelope, dates from 1586. These were used with muzzle-loaders, the base of the cartridge being ripped or bitten off by the soldier before placing in the barrel. It was only when the detonating cap came into use that the paper cartridge answered well in breech-loaders. The modern breech-loader has resulted from a gradual series of improvements, and not from any one great invention. Its essential feature is the prevention of all escape of gas at the breech when the gun is fired by means of an expansive cartridge-case containing its own means of ignition. The earlier breech-loaders were not gas-tight, because the cartridge-cases were either consumable or the load was placed in a strong non-expansive breech-plug. The earliest efficient modern cartridge-case was the pin-fire, patented by Houiller, a Paris gunsmith, in 1847, with a thin weak shell which expanded by the force of the explosion, fitted perfectly in the barrel, and thus formed an efficient gas check. Probably no invention connected with firearms has wrought such changes in the principle of gun-construction as those effected by the expansive cartridge-case. This invention has completely revolutionized the art of gunmaking, has been successfully applied to all descriptions of firearms, and has produced a new and important industry—that of cartridge manufacture.

About 1836, Lefaucheux, a Paris gunsmith, improved the old Pauly system of breech-loading, but its breech action was a crude mechanism, with single grip worked by a bottom lever. The double grip for the barrels was the subsequent invention of a Birmingham gunmaker. The central-fire cartridge, practically as now in use, was introduced into England in 1861 by Daw. It is said to have been the invention of Pottet, of Paris, improved upon by Schneider, and gave rise to considerable litigation in respect of its patent rights. Daw, who controlled the English patents, was the only exhibitor of central-fire guns and cartridges at the International Exhibition of 1862. In his system the barrels work on a hinge joint, the bottom lever withdraws the holding-down bolt; the cartridge is of the modern type, the cap being detonated by a striker passing through the standing breech to the inner face. The cartridge-case is withdrawn by a sliding extractor fitted to the breech ends of the barrels. Daw was subsequently defeated in his control of the patents by Eley Bros., owing to the patent not having been kept in force in France. The modern breech-loading gun has been gradually and steadily improved since 1860. Westley Richards adopted and improved Matthews' top-lever mechanism. About 1866 the rebounding lock was introduced, and improved in 1869. The treble wedge-fast mechanism for holding down the barrels was originated by W. W. Greener in 1865, and perfected in 1873. A very important improvement was the introduction of the hammerless gun, in which the mechanism for firing is placed entirely within the gun. This was made possible by the introduction of the central-fire cartridge. In 1862 Daw, and in 1866 Green, introduced hammerless guns in which the cocking was effected by the under lever. These guns did not attain popularity. In 1871 T. Murcott patented a hammerless gun, the first to obtain distinct success. This also was a lever-cocking gun. About the same time Needham introduced the principle of utilizing the weight of the barrels to assist in cocking. In 1875 Anson and Deeley utilized the fore-end attached to the barrels to cock the locks. From this date hammerless guns became really popular. Subsequently W. W. Greener and some other gunmakers improved the hammerless mechanism. Still greater improvements have since been introduced by Westley Richards, Purdey, and others, including cocking by means of the mainspring. In 1874 J. Needham introduced the ejector mechanism, by which each empty cartridge-case is separately and automatically thrown out of the gun when the breech is opened. The necessary force is provided by the mainspring of the lock. W. W. Greener and some other gunmakers have since introduced minor modifications and improvements of this mechanism. The latest improvement in the modern breech-loader is the single trigger mechanism introduced by some of the leading English gunmakers, by which both barrels can be fired in succession

by a single trigger. This improvement enables both barrels to be rapidly fired without altering the grip of the right hand.

Repeating or magazine shot-guns on the principle of the repeating rifle, with a magazine barrel below the single firing barrel, are also made by some American and other gunmakers (particularly by the Winchester Small Arms Company), but as yet have not come into general use, being comparatively cumbersome and not well balanced. The difficulty of a shifting balance as each cartridge is fired has also yet to be overcome. Several varieties of a combination rifle and shot-gun are also made, for a description of which see RIFLE.

The chief purposes for which modern shot-guns are required are game-shooting, trap-shooting at pigeons, and wild-fowling. The game gun may be any bore from 32 to 10 gauge. The usual standard bore is 12 gauge. The usual weight of the 12-bore double-barrelled game gun is from 6 to 7 ℔ with barrels 30 inches long. These barrels are made of laminated steel twisted and welded, and are known as Damascus barrels, or of forged wrought steel drilled, or more usually of Whitworth fluid-compressed steel. The standard charge is 3 drams of powder and $1\frac{1}{8}$ oz. of No. 6 shot. The ordinary game gun should have a killing circle of 30 inches at 30 yards with the first barrel and at 40 yards with the second. Improved materials and methods of manufacture, and what is known as "choke" boring of the barrels have enabled modern gunmakers to regulate the shooting of guns to a nicety. Choke-boring is the constriction of the diameter of the barrel near the muzzle, and was known in America in the early part of the 19th century. In 1875 Pape of Newcastle was awarded a prize for the invention of choke-boring, there being no other claimant. The methods of choke-boring have since been varied and improved by the leading English gunmakers. The pigeon gun is usually heavier than the game gun, and more choked. It generally weighs from 7 to 8 ℔. In England its weight, by club rules, is restricted to 8 ℔, and its bore to 12 gauge. The standard wild-fowling gun is a double 8-bore with 30-inch barrels weighing 15 ℔, and firing a charge of 7 drams of powder and $2\frac{3}{4}$ to 3 oz. of shot. These guns are also made in both smaller and larger varieties, including a single barrel 4-bore, which is the largest gun that can be used from the shoulder, and single barrel punt guns of $1\frac{1}{2}$-inch bore, weighing 100 ℔. (H. S.-K.)

Gung'l, Josef (1810–1889), Hungarian composer and conductor, was born, 1st December 1810, at Zsámbék, in Hungary. After starting life as a school-teacher, and learning the elements of music from Ofen, the school-choir-master, he became first oboist at Graz, and, at twenty-five, bandmaster of the 4th regiment of Austrian artillery. His first composition, a Hungarian march, written in 1836, attracted some notice, and in 1843 he was able to establish an orchestra in Berlin. With this band he travelled far, even in 1849 to America. It is worth recording that Mendelssohn's complete *Midsummer Night's Dream* music is said to have been first played by Gung'l's band. In 1853 he became bandmaster to the 23rd Infantry Regiment at Brünn, but in 1864 he lived at Munich, and in 1876 at Frankfort, after (in 1873) having conducted with great success a series of promenade concerts at Covent Garden, London. From Frankfort Gung'l went to Weimar to live with his daughter, a well-known German opera singer and local prima donna. There he died, 31st January 1889. Gung'l's dances number over 300, perhaps the most popular being the "Amoretten," "Hydropaten," "Casino," "Dreams on the Ocean" waltzes; "Im Stille Mitternacht" polka, and "Blue Violets" mazurka. His Hungarian march had the honour of being transcribed by Liszt. His music is characterized by the same easy flowing melodies and well-marked rhythm that distinguish the music of Strauss, to whom alone he can be ranked second in this kind of composition. (R. H. L.)

GUN-MAKING.

THE ninth edition of this Encyclopædia carried the history of British service guns up to the year 1878. These guns were of a short, muzzle-loading type, and consisted of a steel barrel, over which was shrunk a series of wrought-iron coils. Forged steel was chosen as the best material for the barrel, on account of the closer nature of its texture and the absence of flaws as compared with wrought iron; it was therefore far less eroded by the action of the powder gases than the more open fibre of wrought iron, in which streaks of slag, due to the imperfect forging or welding operation, are invariably present. The manufacture of large steel forgings was then practically in its infancy, and defects which occasionally appeared in the mass of an apparently sound forging—often the result of imperfect annealing—caused the material to be looked upon as somewhat treacherous, and liable to fracture, without warning, under any sudden stress, unless strengthened by surrounding it with coils of wrought iron. Experience gained from the bursting of guns, by accident or design, had shown that this latter material always showed evident signs of distress before finally fracturing. The coiled iron never flew to pieces as the steel of that period occasionally did. These guns were built up of as few coils as possible, and only in the largest guns were two layers of coils superimposed on the barrel. Thick coils were preferred to thin ones, the argument being that one thick coil cost less than several thin ones, and thus one of the principles of the Armstrong construction was rendered inoperative. At the present time the opposite extreme is favoured, and by the use of wire the full benefit is obtained of the ideal thin coil or hoop, without the disadvantage of excessive weight and cost. Wrought iron is no longer considered the best material; indeed, so far as structural purposes go, it is non-existent. The steel industry has made so much progress since 1880 that steel is looked upon as one of the most trustworthy metals in use.

The gun steel used in England and most foreign countries is prepared by the open-hearth method in a regenerative gas furnace of the Siemens-Martin type. (For a full description of the arrangement see *Ency. Brit.*, 9th edition, vol. xiii. page 294, and *Supp.* IRON AND STEEL.) The steel is run from the furnace into a large ladle, previously heated by gas, and from this it is poured into a cast-iron ingot mould of from 10 to 12 feet high and 2 feet or more in diameter. The external shape of these ingots varies in different steel works, but they are so arranged that, as the ingot slowly cools, the shrinkage of the metal shall not set up dangerous internal stresses. *Forging the barrel.* The top of the ingot is generally porous, and consequently, after cooling, it is usual for about one-third of the length of the ingot to be cut from the top and remelted; a small part of the bottom is also often discarded. The centre of the larger ingots is also inclined to be somewhat unsound, and a hole is therefore bored through them to remove this part. In the Whitworth method of fluid-compressed steel

FIG. 2.—Effects of Forging on Structure of Metal.

this porosity at the top and centre of the ingot does not occur to the same extent, and a much greater portion can therefore be utilized. The sound portion of the ingot is heated in a reheating gas furnace, which is usually built in close proximity to a hydraulic forging press. This press is now almost exclusively used for forging the steel in place of the steam hammers which were formerly an important feature in all large works (Fig. 1, PLATE). The largest of these steam hammers could not deliver a blow of more than some 500 foot tons of energy; with the hydraulic press, however, the pressure amounts to, for ordinary purposes, from 1000 tons to 5000 tons, while for the manufacture of armour plates it may amount to as much as 10,000 or 12,000 tons. For 8-inch guns and those of larger calibre the bored-out ingot is forged hollow on a tubular mandrill, kept cool by water running through the centre; from two to four hours' forging work can be performed before the metal has cooled down too much. Generally, after one end of the ingot has been forged down to the proper size, it is then reheated and the other end similarly treated. The forging of the steel and the subsequent operations have a very marked influence on the structure of the metal, as will be seen from the micro-photographs of Fig. 2 (PLATE); (*a*) and (*b*) show the structure of the cast steel of the actual ingot. From these it will be noticed that the crystals are very large and prominent, but as the metal passes through the various operations they become smaller and less pronounced. Thus (*c*) and (*d*) show the metal after forging; (*e*) shows the pearlite structure with a magnification of 1000 diameters, which disappears on the steel being oil-hardened; and (*f*) shows the oil-hardened and annealed crystals. At the Bofors Works in Sweden gun barrels up to 15 centimetres calibre are often formed of an unforged cast steel tube, but this practice, although allowing of the production of an inexpensive gun, is not followed by other nations.

After the forging is completed it is annealed by reheating and cooling slowly, and a number of test pieces are cut from each end tangentially to the circumference of the bore. Half the number of these are tested to ascertain the quality of the steel in the soft state, and the remainder are hardened and annealed in the way described hereafter for the treatment of the gun forging, and tested partly for tensile test and partly for bending. It is found that the quality of the steel is greatly improved by forging, so long as this is not carried so far as to set up a laminar structure in the metal, which is thereby rendered less suitable for gun construction, being weaker across the laminæ than in the other directions. It is then termed overforged.

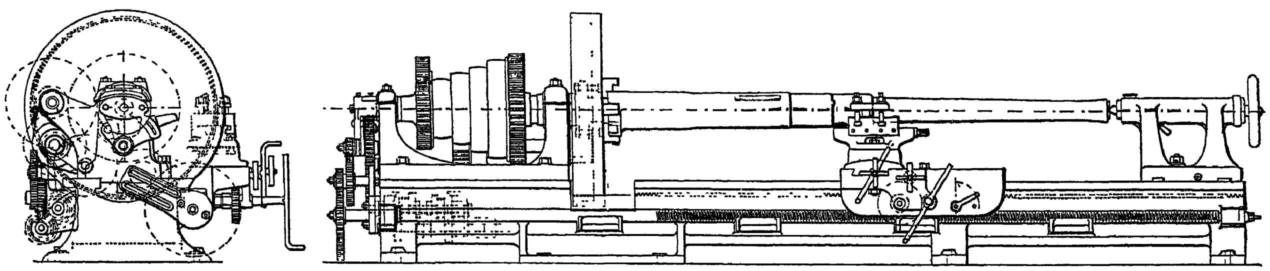

Fig. 3A.

If the tests are satisfactory the forging is rough-turned and bored, and then reheated to a temperature of 1600° F., and hardened by being plunged into a vertical tank of rape oil. This process is a somewhat critical one; great care must be observed in uniformally heating the whole of the forging in a furnace in close proximity to the oil tank into which it is plunged, and it must be completely submerged as rapidly as possible. In some cases the oil in the tank is circulated by pumping, so that uniformity of cooling is ensured, and in addition the tank is surrounded by a water jacket, which also helps to keep it at a uniform heat. The forging is subsequently again heated to from 900° F. to 1200° F., and allowed to cool slowly by being placed in warm sand, &c. This last operation is termed annealing, and is intended to dissipate any internal stress which may have been induced in the forging by any of the previous processes, especially that of oil-hardening.

After this annealing process a second set of test pieces, two for tensile and two for bending test, are cut from each end of the forging in the positions above mentioned. For guns of less than 3-inch calibre only half this number of test pieces is taken, and with hoops of less than 48 inches in length the test pieces are taken only from the end which formed the upper part of the cast ingot. In all cases of annealed steel the test piece of 2 inches length and 0·533 inch diameter must not break with less than 34 tons per square inch or more than 44 tons per square

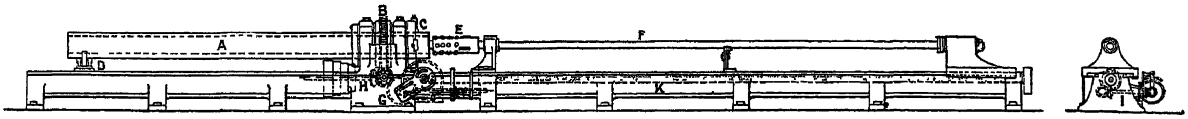

Fig. 3B.

inch; the elongation must not be less than 17 per cent., nor the elastic limit less than 21 tons per square inch. For breech screws the steel is made of a harder quality, as it has to resist a crushing stress. These are the tests required in England, but they differ in different countries; for instance, in France a harder class of steel is employed, and the tensile strength must not be less than 46 tons, nor the elastic limit less than 25 tons per square inch, neither must the elongation fall below 15 per cent.

Steel having about 3 per cent. of nickel is now being used to some extent for the smaller guns, and offers certain advantages. It does not require tempering, and in the soft state has a tensile strength equal to that of ordinary tempered gun steel, with a higher elastic limit and about the same elongation. The structure is of a very uniform and finely crystalline nature.

Assuming that the tests of the annealed forging are satisfactory, the forging, which we will suppose to be a barrel, is tested for straightness, and, if necessary, rectified; it is then bored out to nearly the finished dimension and rough- and afterwards fine-turned in a lathe, on the exterior (Fig. 3A). In the meantime the other portions of the gun are in progress, and as it is far easier to turn down the outside of a tube than to bore out its interior to the exact

measurements required to allow for shrinkage, the interior of the jacket and other hoops are bored out in a boring-machine and finished before the exterior of the barrel is fine-turned; and so for any other hoop. The process is illustrated in Fig. 3B. The barrel or hoop A to be bored is passed through the revolving headstock B and firmly held by jaws C, the other end being supported on rollers D. A head E, mounted on the end of a boring-bar F, is drawn gradually through the barrel as it revolves by the leading screw K actuated by the gear G. The boring head is provided with two or more cutting tools, and also with a number of pins of brass or pieces of hard wood to act as guides, in order to keep the boring head central after it has entered the barrel. The revolving headstock B is driven by a belt and worm-gear H.

With wire guns the procedure is somewhat different. The wire is wound on to its tube, which has been previously fine-turned; the exterior diameter of the wire is then carefully measured, and the interior of the covering tube or hoop finished to suit. The covering hoop is often not allowed any shrinkage, as it is simply intended as a protection to the wire and to give longitudinal strength; but in order to place it over the wire it must be heated, and thus some little contraction always does take place, as it is found that any hoop on cooling, after being heated, is somewhat smaller than it was originally. The heat to

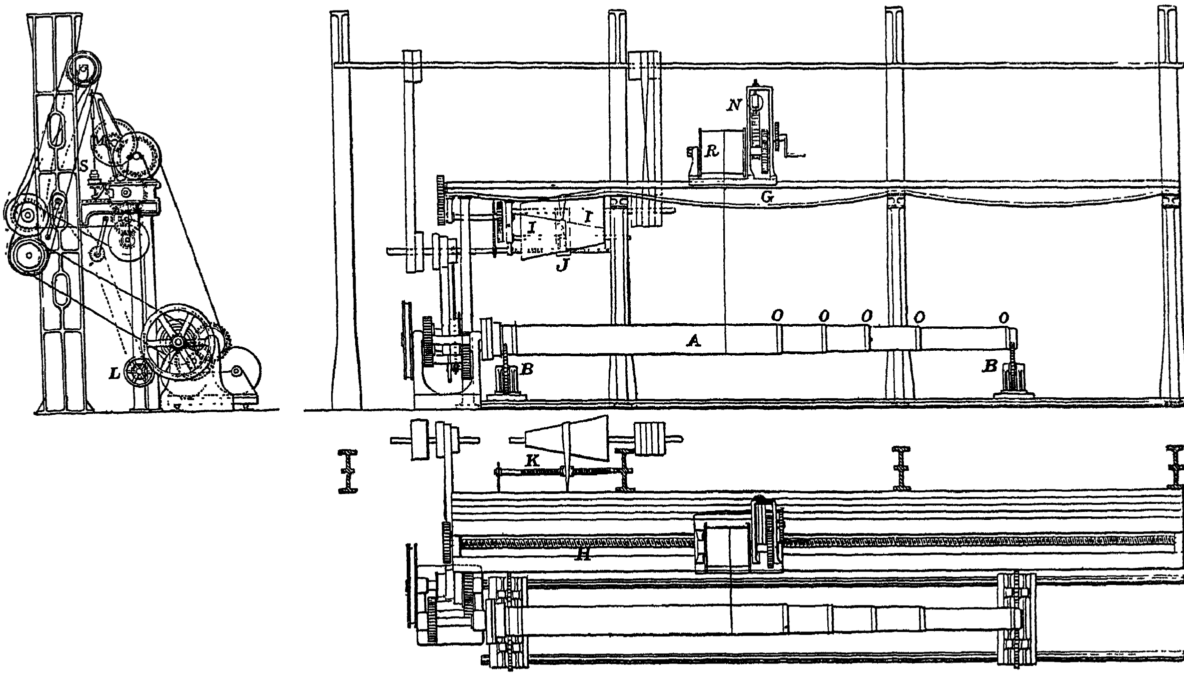

Fig. 4.

which these hoops are brought for shrinking never exceeds, or even approaches, that used in annealing, otherwise the modifying effects of the annealing process would be interfered with.

In the earliest modern type B.-L. guns the breech screw engaged directly with a screw thread cut in the barrel, which thus had to resist a large portion of, if not all, the longitudinal stress. This was, until quite recently, the system adopted in France, but it has some serious objections. The principal one is, that the barrel must be made of large external diameter to meet the longitudinal stress, and this in consequence reduces the circumferential strength of the gun. Again, the diameter of the screw is always considerably larger than the breech opening, and so an abrupt change of section takes place, which should always be avoided in structures liable to sudden shocks. The only advantage is, that the thick barrel gives stiffness against bending, but this liability is met in a better manner in all the later patterns of British guns by the long continuous outer tubes which are shrunk over the barrel or wire. In the English system the breech screw is engaged either in the breech piece, *i.e.*, the hoop which is shrunk on over the breech end of the barrel, or in a special bush screwed into the breech piece. The latter method suits the latest system of construction, in which the breech piece is put on the barrel from the muzzle, while with the earlier type it was put on from the breech end.

Hoop construction.

With the earlier constructions short hoops were used whenever possible, as, for instance, over the chase of the gun, principally because the steel in short lengths was less likely to contain flaws. But as the metallurgical processes of steelmaking developed the necessity for this disappeared, and the hoops have become gradually longer. This has, however, increased correspondingly the difficulties in boring and turning, and to a much greater extent those encountered in building up the gun. In this operation the greatest care has to be taken, or warping of the long tubes will occur during heating. The tubes are heated in a vertical cylindrical furnace, gas jets playing on both the exterior and interior of the tube. When sufficiently hot, the tube is raised out of the furnace and dropped vertically over the barrel or other portion of the gun. In cooling it shrinks longitudinally as well as circumferentially, and in order to avoid gaps it is, after being placed in position, cooled at one end to make it grip by a ring of water jets, while the other portions are kept hot by rings of burning gas flames, which are successively extinguished to allow the hoop to shorten gradually, and thus avoid internal longitudinal stress. A stream of water is also directed along the interior of the gun during the building-up process, in order to ensure the hoop cooling from the interior. After the building up has been completed, the barrel is fine-bored and ground, then chambered and rifled. The breech is then screwed either for the bush or breech screw, and the breech mechanism is fitted to the gun.

In order to obtain longitudinal strength, the outer

tubes are so arranged that each hooks on to its neighbour from muzzle to breech. Thus the chase hoop hooks on to the barrel by a step, and the succeeding hoops hook on to each other until the jacket is reached; this is secured to the breech piece by a strong collar and screwed ring. In some of the later patterns of guns there is usually only a chase hoop covering the forward portion of the gun and a jacket covering the breech portion—an arrangement which simplifies the design, but greatly increases the difficulties of manufacture.

Wire guns are now made of almost all calibres, ranging from 3-inch to 12-inch. Many authorities object to guns of less calibre than 4·7 inch being wound with wire, as they consider that on diameters so small the interior surface of each layer of wire is over-compressed, while the exterior is too much extended; but if the thickness of the wire is proportioned to the diameter of the tube on which it is wound, there is no reason why this should be the case. The wire is wound on the barrel with a certain tension, ascertained by calculation, and varying from about 50 tons per square inch for the layers first wound on the gun to about 35 or 40 for the outer layers. To fasten the wire at the beginning and end, several methods are adopted. In the Woolwich system a narrow annular ring (O O, Fig. 4), with slots cut into one of its faces, is shrunk on to the gun, and into these slots one end of the wire is inserted and secured in position by a steel-screwed plug, each layer of wire being fastened at the beginning and end in this way. At Elswick the wire is fastened by bending it into a circular-cut groove in a similar annular ring, but the wire is only fastened off in the same way after several layers have been wound. With each succeeding layer of wire the interior layers are compressed, and these in turn compress the barrel; it is therefore necessary, in order to prevent the fatigue of the material of the barrel, to make it relatively thick, or, better still, to have an outer barrel superimposed on the inner one. This latter arrangement is now used in all guns larger than 4·7 inch, but it will probably be extended to guns of even 4-inch calibre; it is not so important with smaller guns, where the barrel is always comparatively thick, and thus meets the conditions. With modern guns the interior of the outer barrel is bored taper, the larger end being towards the breech, and the exterior of the inner barrel or liner is made taper to correspond. The latter is then inserted in the outer barrel while both are cold, and forced into position by hydraulic pressure. The details of the machines for winding on the wire differ somewhat in different works, but all are arranged so that any desired tension can be given to the wire as it is being wound on to the gun.

Wire construction.

The wire is manufactured in much the same way as ordinary wire. A red-hot bar of steel, gradually rolled down between rollers to a section about double that which it is finally intended to have, is annealed and carefully pickled in an acid bath to detach any scale. It is then wound on a drum, ready for the next process, which consists in drawing it through graduated holes made in a hardened steel draw-plate, the wire being often annealed and pickled during this process. The draw-plate holes vary in size from slightly smaller than the rolled bar section to the finished size of the wire, and, as a rule, the sharp corners of the wire are only given by the last draw. It is found that considerable wear takes place in the holes of the draw-plate, and a new plate may be required for each hank of 500 or 600 yards of wire. Great importance is attached to the absence of scale from the wire when it is being drawn, and after pickling, the rolled bar and wire are treated with lime or some similar substance to facilitate the drawing. The tests for the finished wire are as follows:—It has to stand a tensile stress of from 90 to 110 tons per square inch of section, and a test for ductility, in which a short length of the wire is twisted a considerable number of turns in one direction, then unwound, and retwisted in the opposite direction without showing signs of fracture. It will be seen that the wire is extremely strong, and the moderate stress of from 25 to 30 tons per square inch, which at most it is called upon to withstand in a gun, is far less than it could endure with perfect safety.

The wire, after manufacture, is made up into hanks for storage purposes, but when required for gun construction it is thoroughly cleaned and wound on a drum R about 3 feet 6 inches in diameter, which is placed in one portion of the machine in connexion with a powerful band friction brake M. The wire is then led to the gun A placed between centres or on rollers BB, parallel to the axis of the wire drum. By rotating the gun the wire is drawn off from the drum against the resistance of the band brake, which is so designed that, by adjusting the weight S, suspended from the brake strap, any desired resistance can be given in order to produce the necessary tension in the wire as it is being wound on the gun. The stress on the wire is indicated on the dial N. The headstock, containing the drum of wire, is capable of being moved along the bed G by a leading screw H, driven by a belt through variable speed cones I; the belt is moved along the cones by forks J, traversed by screws K, which in their turn are actuated by chain belts from the hand-wheel L. The traversing speed is regulated to suit the diameter of winding by moving the belt along the speed cones. The wire is rectangular in section, 0·25 inch wide and 0·06 inch thick, and after it has been wound on to the gun it presents a very even surface, which does not generally require any further preparation. The diameter over the wire is gauged, and the jacket or other covering hoop is carefully bored equal to this, if no shrinkage is to be allowed, or the dimension is diminished in accordance with the amount of shrinkage to be arranged for. The gun is built up, after wiring, in the same manner as a gun without wire, the jacket or other hoop being heated in the vertical gas furnace, and when hot enough dropped into place over the wire, cooled by the ring of water jets at the end first required to grip, and kept hot at the other, exactly as before described.

Strictly speaking, the description of obturators should be included in that of breech mechanism; but as there are, at present, two systems of obturation in use in the British service, and as the design of the breech mechanism depends in a large measure on the system adopted, we propose to consider this part of the subject separately. The purpose of the obturator is to make the breech end of the gun gas-tight, and

Obturators.

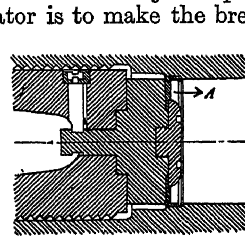

Fig. 5.

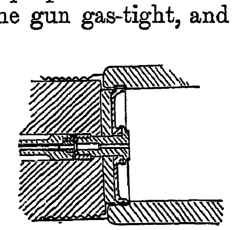

Fig. 6.

to prevent any escape of gas past the breech arrangements. In the first Armstrong B.-L. guns this object was attained by fitting to the breech block a copper ring coned on the exterior; the cone surface was screwed tightly up, by the breech screw, against a corresponding copper ring fitted at the breech opening of the gun chamber. This was a positive method, but one which could be used only when it was possible to jam the copper surfaces together by a powerful screw. In the French service B.-L. guns have been in use since about 1863, and one of the first systems of obturation was arranged on the same principle as the leather packing ring of the hydraulic press. On the face of the breech screw a steel ring, A, of a cup form, was fastened by a central screw; the outer lip of the cup fitted against a slightly coned seating formed in the breech of the gun (Fig. 5). When the gun

was fired, the gas pressure expanded the cup ring and forced it into close bearing against the breech screw and the seating in the gun, thus preventing any escape of gas. Very similar to this was the Elswick cup obturation (Fig. 6), introduced by the Elswick Ordnance Company, except that its bearing face was slightly rounded, so that on

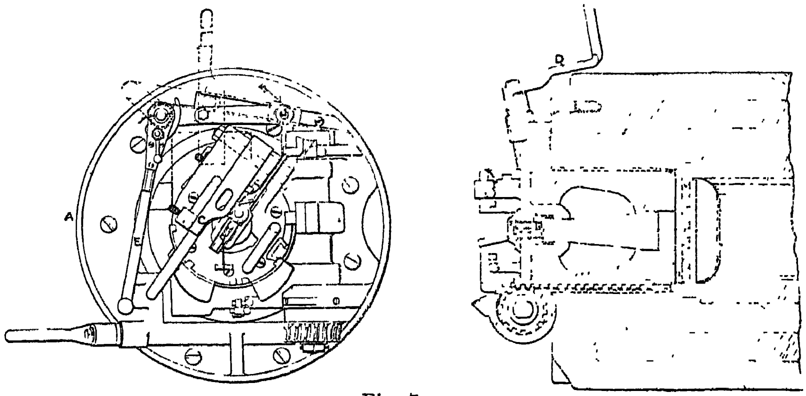

Fig. 7.

setting back against the breech screw it became flattened and expanded the lip more than with the French obturator. Besides this, the seating in the gun was formed of a copper ring, let into the gun, which could be renewed when necessary. Both these types of obturators were perfectly efficient if treated with care, and with the Elswick plan the parts liable to damage could be replaced, though a slight abrasion of the cup or seating allowed the gas to escape, and so accentuated the defect with each round fired; unless, therefore, the fault was immediately remedied, considerable damage was caused to the gun after a few rounds. The Broadwell gas ring, used in some French B.-L. guns and by Krupp for his guns, and described in the ninth edition of this Encyclopædia, depends on the same principle, and is open to the same objections. For all his latest pattern guns Krupp uses the metallic cartridge case, to be described lower down.

After this there was introduced into the French service by Colonel De Bange a new form of obturator, which has since been adopted by the British and other Governments. It consists of a pad (Fig. 8) made up of a strong annular-shaped canvas bag, containing a mixture of asbestos fibre and mutton suet; the bag with its contents is placed in a properly formed die and subjected to hydraulic pressure. The pad is placed on the front of the breech screw, and it is protected on its faces by discs of metallic tin or copper, having steel wedge rings on the outer edges; the circumference of the complete pad and discs is slightly coned, and fits into a corresponding seating formed at the breech end of the gun, the canvas of the circumference of the pad being in immediate contact with the gun. In front of the pad is placed a strong steel disc formed with a spindle, and called a mushroom head, the spindle passing through the hole in the pad and through the breech screw being secured in rear by a nut. The firing vent is generally drilled through the mushroom head and spindle, and is then termed an axial vent, to distinguish it from the radial vent bored through the body of some guns. On the gun being fired the gas exerts a great pressure on the mushroom head, which compresses the pad and forces it out on the circumference into close contact with the seating, thus forming a perfect gas seal. It is found that this apparently delicate arrangement will stand considerable ill-usage and act perfectly for an indefinite time, and as it is easily replaced, it is looked upon as one of the best forms of obturator. In some countries the Freyre obturator is in use; this has a somewhat similar axial head to the De Bange, but the asbestos pad is replaced by a single steel wedge ring into which the axial head fits. On firing the gun the head is forced into the wedge ring, and thus expands it against the seating of the gun.

We have now to consider one other means of obturation, viz., metallic cartridge cases. These act on the same principle as the cup obturation, and are extremely efficient for the purpose; moreover, they have certain advantages when used for small guns. The idea has developed from the use of such cartridges in small arms, and larger cartridges of the same type were introduced in 3-pounder and 6-pounder guns by Hotchkiss and Nordenfelt about the year 1880. Then in 1886 the Elswick Company produced a 36-pounder (soon converted to a 45-pounder) of 4·7 inches calibre, with the powder charge contained in metallic cases, and about 1888 a 6-inch 100-pounder gun, using similar cartridges. Metallic cases of a short pattern were also used in guns of 8-inch and 10-inch calibre, and although their action was quite efficient, they were heavy to manipulate, and it was considered that for guns above 6-inch calibre the De Bange obturation was the most advantageous. Krupp, however, uses cartridge cases with guns even of 12 inches calibre, but this is, in all probability, due to the difficulties attending the use of the

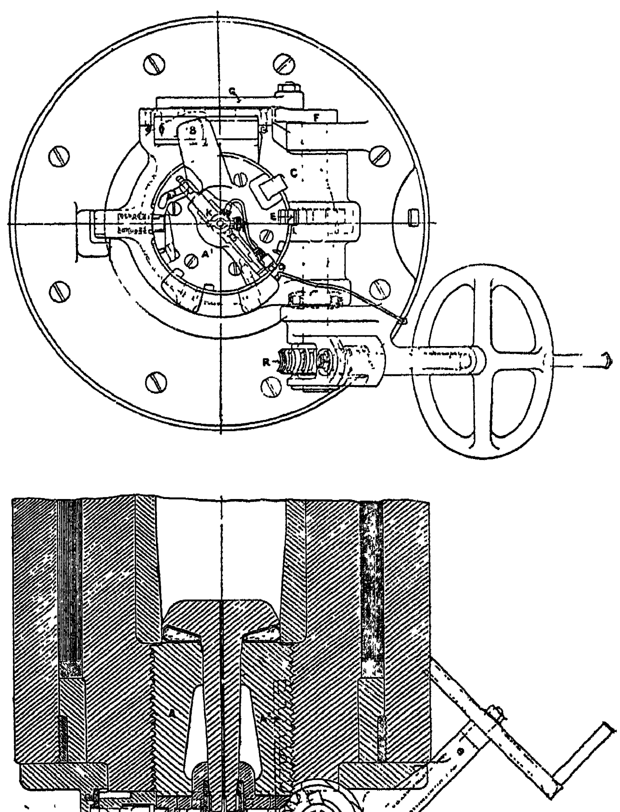

Fig. 8.

ordinary forms of obturation with the wedge breech system, especially now that the use of smokeless powder, which is exceedingly searching in its action, is almost obligatory. With smokeless powder any small defect in the ring obturators is immediately attacked, and increases with such

rapidity as quickly to render the obturator useless, even if it does not seriously damage the gun. There are, however, certain disadvantages with cartridge cases, such as their weight, the difficulty of stowage, &c., which has caused a reaction in England in favour of the De Bange system, especially for guns of 6-inch and even smaller calibres. Most other nations, however, still retain cartridge cases for guns up to 6-inch calibre. Aluminium cases have been

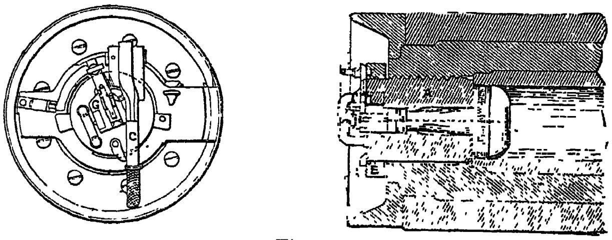

Fig. 9.

experimented with, but up to the present have not proved satisfactory.

Breech mechanism.

One of the most important parts of the gun is the breech mechanism, and a vast amount of ingenuity is expended in designing this, that it may be as simple and at the same time as effective and quick-acting as possible. In England the interrupted breech screw is used. This is a French invention, and consists of a strong screwed plug engaging with a corresponding screw thread cut on the interior of the breech opening of the gun. The screw surface of the breech plug is cut away in sections equally divided and alternating with the threaded portions. The screw surface of the breech opening of the gun is similarly cut away, so that the plug can be pushed nearly home into the breech opening without trouble; by then revolving the breech screw through a small angle, the screwed portions of the plug and breech opening engage. Thus if three sections are cut away, the angle of revolution necessary to ensure a full engagement of the screw surfaces will be 60°. A modification of the cylindrical breech screw (called the Welin screw), in which the loss of the threaded surface by the interrupted portion is reduced, has lately been introduced into the English service. In the older types of mechanism the breech was opened in from three to four different operations, which involved considerable loss of time. Thus in the earlier patterns of 10-inch B.-L. gun, to open the breech the cam lever C was folded up so that it engaged the pin J in connexion with the ratchet lever E (Fig. 7). This was then worked, and disengaged the breech screw from the threads cut in the gun; the cam lever was then folded down so as to start the breech screw, and the winch handle D rotated to withdraw the screw and swing it clear of the breech opening. During these operations the firing lock was actuated and made safe, but the fired tube had to be extracted by hand. To close the gun these various operations were reversed. To open or close the gun would certainly occupy at least half a minute with trained men. To compare with this a modern 12-inch breech mechanism is shown in Fig. 8. In order to open this breech it is only necessary to turn the hand-wheel continuously in one direction, and to close it again the motion of the hand-wheel has only to be reversed; either closing or opening the breech occupies about six seconds. Supposing the breech closed, the hand-wheel when rotated gives motion to the link G through the worm-wheel R and crank F. By this means the tooth B is moved from its extreme right position to the left, and so disengages the breech screw A from the threads in the gun; the rack A^2 on the breech screw then comes into gear with the pinion E, and draws the breech screw out of the gun into the carrier ring C which finally swings on the axis pin RF and clears the breech opening. While the opening is being performed the firing lock K is operated by the cam groove A^3, which puts the firing mechanism, either electric or percussion, to safety by withdrawing the firing needle, extracts the fired tube, and leaves the primer chamber open for a fresh primer. All these operations are performed in the reverse order on closing. With both these types of mechanism the De Bange system of obturation, with the pad only slightly coned, is used. With smaller guns the mechanism is still simpler, as less power is required for opening the breech. Thus with the 6-inch B.-L. gun, Mark IV., date about 1885 (Fig. 9), the breech is opened in three separate operations:—(*a*) the cam-lever C, which also locks the breech, is raised into the vertical position and pulled over to the left, disengaging the screw threads; (*b*) the cam lever is folded down, so that the cam acting on the rear face of the gun releases the De Bange obturator, and the screw A is then pulled by hand through the carrier ring B out of the breech; and (*c*) the carrier ring and breech screw are revolved together to the right, clear of the breech opening. In a modern 6-inch gun fitted with De Bange obturator all these operations are combined, and the mechanism worked by a horizontal hand lever, which is moved from left to right through an angle of about 200°. The hand lever A (Fig. 10) moves a link B connected to a pin C on the breech screw D, and disengages the screw from the gun; a small lateral movement is then given to the axis pin of the carrier, so as to allow the obturator pad E to swing out of its seating; when this is quite free the whole mechanism revolves on the axis pin, and thus clears the breech opening. The

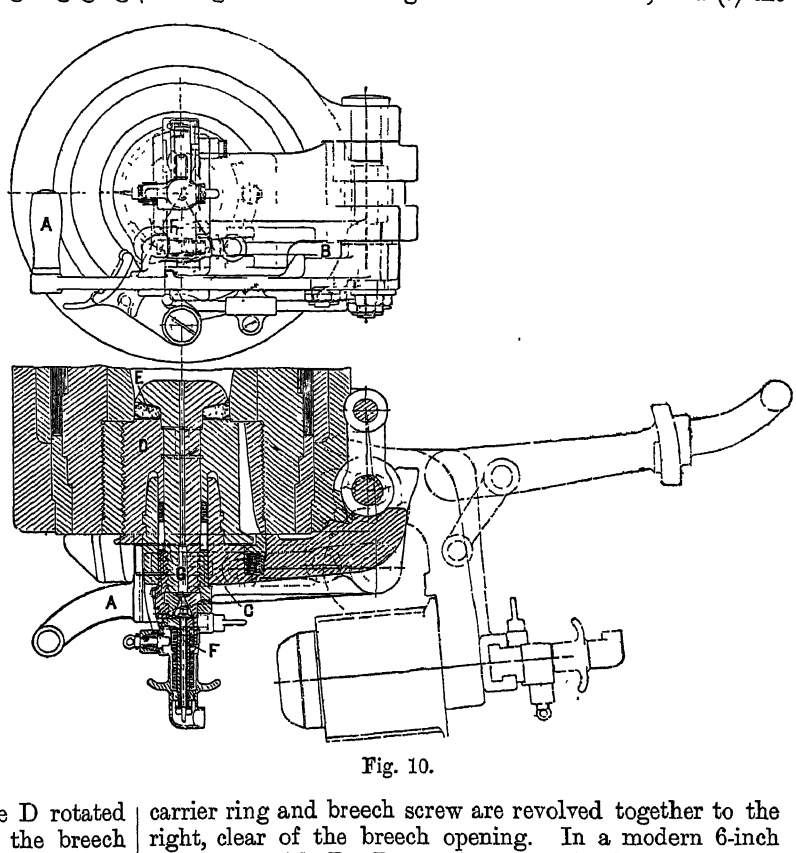

Fig. 10.

firing lock F is actuated at the same time and ejects the fired tube G, and a new tube is inserted while the gun is being loaded, so that immediately the breech is closed the charge can be fired without loss of time. In the old mechanisms the breech had to be closed first and the firing tube inserted afterwards.

The breech mechanism for guns firing metallic cartridge cases is somewhat simpler than that for the De Bange obturation, due principally to the fact of the firing primer being contained in the cartridge case, when this is intro-

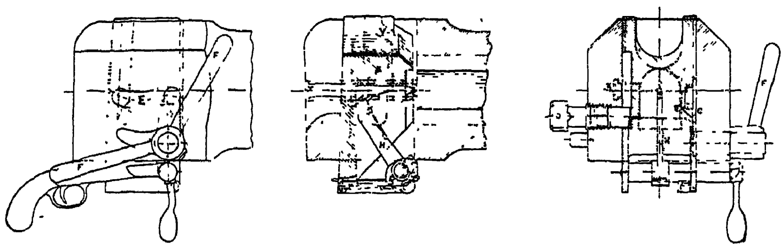

Fig. 11.

duced into the gun. In the Hotchkiss and also in the Skoda systems the mechanism is of the vertical breech block type; the actuating lever F (Fig. 11) is on the right side of the gun, and is connected to a powerful crank arm C working in a groove E cut in the breech lock. By pulling the lever towards the rear the crank arm forces down the block A and extracts the fired case by an extractor X, which in the Hotchkiss gun is actuated by a cam groove Y, also cut on the side of the block. As the mechanism is opened the hammer H is cocked ready for the next round. To close the mechanism the lever is pushed over to the front, and by releasing the trigger sear by pulling the lanyard the hammer falls and fires the cap of the cartridge case. Automatic gear can be fitted which opens the breech and extracts the fired case by means of a supplementary mechanism and strong spring actuated by the

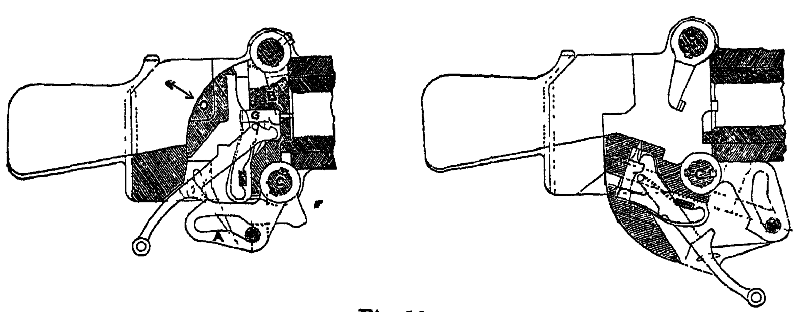

Fig. 12.

recoil of the gun; when a new cartridge is pushed into the gun the breech, which was retained by the extractor, is released, and closes automatically.

The Nordenfelt mechanism (Fig. 12) consists of a breech block B and a wedge O to secure it. A hand lever on the shaft C is pulled to the rear, and this works the action cam A, which pulls down the wedge; the breech block B is then caused to rotate, and falls back to the rear. This motion of the breech block actuates the extractor and extracts the case. While the wedge is being withdrawn the firing pin G is pulled back and cocked for the next round. The mechanism is closed by reversing the hand lever, which rotates the breech block upwards, and pushes home the cartridge case; the wedge is then forced up, and secures the breech block.

For larger guns the Elswick type of coned screw has found much favour, and has been fitted to guns of all calibres from 3-inch to 6-inch, both for the British and numerous foreign Governments. The breech screw is formed partly conical and partly cylindrical, to facilitate its entrance and its exit; this form, moreover, is taken advantage of by cutting the interruptions in the screwed surface alternately on the coned part and on the cylindrical part, so that there is a screw surface all round the circumference of the breech screw. By this means the stress is taken all round the circumference, both of the breech screw and in the gun, instead of in portions alternately, as with the ordinary cylindrical form of breech screw. This form of breech screw can also be used with De Bange obturation and the actuating mechanism similar to that already described. The breech screw F (Fig. 13) is mounted on a carrier D pivoted on the right side of the gun. On the rear face of the breech screw projects a pin A, which is connected to the horizontal hand lever E by a block B, sliding in a groove cut in the carrier and link C. When the hand lever is pulled from left to right to open the gun, the link pulls the sliding block across the rear face of the breech screw, and rotates it until the screw threads are disengaged; the sliding block then comes to a stop in the carrier, and the whole mechanism can be revolved on the axis pin G, clear of the breech opening. This then also acts on an extractor H, which extracts the fired cartridge case a short distance, so that it is easily removed by hand; it would be dangerous to the gun's crew for these heavy cartridge cases to be violently ejected. On first moving the hand lever to open the gun the firing mechanism is put to safety by slightly withdrawing the firing needle, and it is impossible to fire the gun until the lever is quite closed. To fire by percussion, the needle is drawn back by hand until it is cocked; by then pulling the lanyard attached to the trigger J, the needle is released and fires the primer.

Rifling.

The rifling of a gun is the term given to the numerous shallow grooves cut spirally along the bore; the rib left between two grooves is called the "land." The machine used for rifling modern guns is very similar to that employed for the old muzzle-loaders; but as guns have kept increasing in length, the difficulties of their manufacture have increased also, and it has only been by improving the mechanical appliances that the various obstacles have been surmounted and a steady progress made possible. The rifling machine (Fig. 14) is a special tool used in gun construction only, and is in reality a copying machine. A steel or cast-iron bar J, which forms the copy of the developed rifling curve, is first made. The copying bar—which is straight if the rifling is to be uniform, but curved if it is to be increasing—is fixed inclined at the proper angle to standards K on the machine. The cutting tool is carried at one end, C, of a strong hollow cylindrical rifling bar B, the other end of which is fixed to a saddle M. This is moved along the bed of the machine by a long screw N, and the rifling bar is consequently either pushed into the gun or withdrawn by the motion of the saddle along the machine. During this motion it is made slowly to rotate by being connected to the copying bar by suitable gearing, I; it will thus be seen that the cutting tool will cut a spiral groove along the bore of the gun in strict conformity with the copy. In most English machines the cutting tool cuts only as the rifling bar is drawn out of the gun; during the reverse motion the cutter F is withdrawn out

of action by means of a wedge arrangement D, actuated by a rod passing through the centre of the rifling bar, which also pushes forward the tool at the proper time for cutting. One, two, or three grooves may be cut at one time, the full depth being attained by slowly feeding the tool after each stroke. After each set of grooves is cut the rifling bar or the gun is rotated, so as to bring the cutters to a new position.

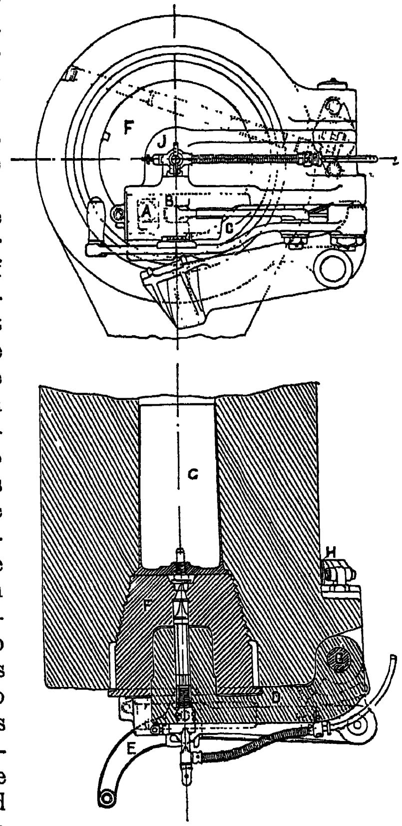

Fig. 13.

All modern guns are rifled on the poly-groove system, *i.e.*, a considerable number (from four to six per inch of diameter) of shallow grooves are cut all round the bore of the gun; the stress induced on the rifling, in forcing the projectile to rotate during its passage along the bore, is thereby distributed around the circumference. In the old muzzle-loaders a few deep and wide grooves only were cut, so that the metal studs fixed in the projectile should not be too numerous, and thus unduly weaken its walls. When the studs were superseded by the copper gas check, more numerous grooves were cut so as to distribute the rotational pressure. This was a great improvement, as the powder gas expanded the edge of the gas check, and so prevented the escape of gas over the projectile, as in the previous systems.

The first type of driving band used in modern breech-loading guns was a broad band of copper fixed to the base of the projectile, but this was expensive, and not altogether satisfactory. Mr Vavasseur then devised the plan of pressing, by hydraulic or other means, a comparatively narrow band of copper into a recessed groove cut near the base of the projectile; this proved most satisfactory, and has now been universally adopted. It will be seen that with breech-loading guns the projectile is better centred, and the copper driving band forms a definite stop for the projectile; in consequence, the capacity of the gun chamber is practically constant. In addition, the use of a copper band ensures a uniform resistance while the projectile is being forced through the gun, and it also prevents the escape of gas. These elements have a very great influence on the accuracy of the gun, and fully account for the vastly superior results obtained from breech-loading ordnance as compared with the muzzle-loading type. Many authorities believe that the best results are obtained when the projectile is fitted with two copper bands, one near the head and the other near the base. No doubt it is better centred when so arranged, but such projectiles can only be fired from guns rifled with a uniform twist, and it must also not be forgotten that the groove formed for the front band in the head of the projectile necessarily weakens the part of the shot which should be strongest.

Projectiles with a driving band at the base only can be fired from guns rifled either uniformly or with increasing twist. The pitch of the rifling or the amount of twist depends altogether on the length of the projectile; if this is short, a small amount of twist only is necessary; if long, a greater amount of twist must be arranged for in order to spin the shell more rapidly. Professor Greenhill has shown that the pitch of the rifling necessary to keep a projectile in steady motion is independent of the velocity, of the calibre, or of the length of the gun, but depends principally on the length of the shell and on its description, so that for similar projectiles one pitch would do for all guns.

The following table has been calculated from Professor Greenhill's formula :—

Length of projectile in calibres.	Minimum twist at muzzle of gun requisite to give stability of rotation expressed in 1 turn in n calibres.			
	Cast iron common shell; cavity $=\frac{8}{27}$ths vol. of shell. (Density of cast iron 7·207.)	Palliser shell; cavity $=\frac{1}{8}$th vol. of shell (Density of chilled iron 8·000.)	Solid steel bullet. (Density of steel 8·000.)	Solid lead and tin bullets of similar composition to M.-H. bullets. (Density of alloy 10·9.)

In most modern guns the projectile varies in length from 3·5 to 4 calibres, so that the rifling is made to terminate at the muzzle with a twist of 1 turn in 30 calibres, which is found ample to ensure a steady flight to the projectile. With howitzers the projectile may be 4·5 calibres long, and the rifling has to be made of a shorter pitch to suit. The relative merits of uniform and increasing rifling depend on the description of gunpowder used in the gun; for quick-burning explosives most authorities favour the increasing twist, while for slow-burning powder it would appear that the uniform twist has the advantage. So many considerations have to be taken into account in this important question, that it would not be possible to detail them here. We give, in the following table, the pressures between the rifling and driving band of the projectile, which have been calculated from the experiments carried out by Sir Andrew Noble with some 4·7-inch guns. These results are obtained by using the formulæ shown in *Ency. Brit.*, vol. xi. p. 295 :—

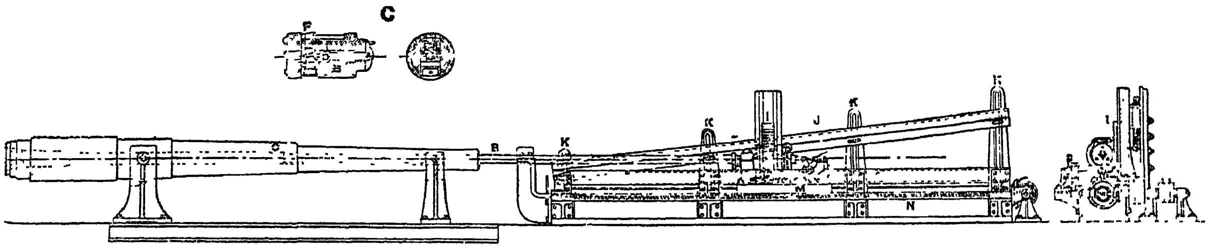

Fig. 14.

Travel of shot in bore in feet.	Total thrust, &c., on base of shot in tons.	Uniform Rifling. Total thrust in tons between driving surface of grooves and ring of projectile.	Velocity in ft. secs.	Parabolic Rifling. Total thrust between driving surface of groove and ring of projectile in tons.

In order to understand properly the principles of gun construction, it is necessary to study the theoretical considerations of the stresses set up in the metal of the gun by the pressure of the powder gases, or by the shrinkage of the tubes in built-up guns or the tension of the wire in wire-wound guns.

For this purpose take a small brick-shaped piece of the metal of the tube (see Fig. 15), and suppose its dimensions to be defined as follows :—

(i.) By two adjacent concentric cylinders of radii r and $r+\delta r$,

(ii.) By two consecutive radial planes at an angle $\delta\theta$,

(iii.) By two transverse planes at distances x and $x+\delta x$ from one end,

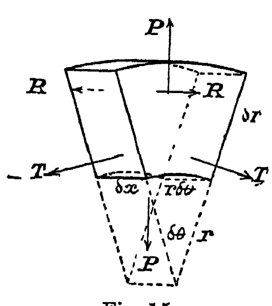

Fig. 15.

so that the width of the lower part of the element will be $r\delta\theta$, its depth δr, and thickness δx.

Let the tube be acted upon by the powder gases, which will induce in the small piece of metal—

T = a circumferential stress,

P = a radial stress,

R = a longitudinal stress,

and assume by these stresses that the piece is slightly altered in all its dimensions, so that the radius increases by u and the thickness by $d\xi$, thus—

$r\delta\theta$ becomes $\quad r\delta\theta\left(1+\frac{u}{r}\right)$,

so that the circumferential extension $=\frac{u}{r}=e$,

δr becomes $\quad \delta r\left(1+\frac{du}{dr}\right)$,

and the radial extension $\quad =\frac{du}{dr}=f$,

δx becomes $\quad \delta x\left(1+\frac{d\xi}{dx}\right)$,

and the longitudinal extension $\quad =\frac{d\xi}{dx}=g$.

Putting $A=\frac{1}{3n}+\frac{1}{9k}$, the longitudinal dilatation for unit stress,

$B=\frac{1}{6n}-\frac{1}{9k}$, the transverse contraction for unit stress for any single force acting alone (see *Ency. Brit.*, vol. vii. p. 806).

Therefore, when the three forces are acting on the element together we have

$$\left.\begin{aligned} e&=AT-B(P+R)\\ f&=AP-B(T+R)\\ g&=AR-B(P+T)\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

or since $\quad \frac{B}{A}=\sigma$, Poisson's ratio,

and putting $\frac{1}{A}=M$, Young's modulus of elasticity, we have

$$\left.\begin{aligned} Me&=T-\sigma(P+R)\\ Mf&=P-\sigma(T+R)\\ Mg&=R-\sigma(P+T)\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

We have also (see *Ency. Brit.*, vol. xv. p. 745)

$$T=\frac{d}{dr}(Pr) \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

From equations (2) we obtain

$$T=\frac{M}{(1+\sigma)(1-2\sigma)}\{(1-\sigma)e+\sigma(f+g)\} \quad . \quad . \quad (4)$$

$$P=\frac{M}{(1+\sigma)(1-2\sigma)}\{(1-\sigma)f+\sigma(e+g)\} \quad . \quad . \quad (5)$$

$$R=\frac{M}{(1+\sigma)(1-2\sigma)}\{(1-\sigma)g+\sigma(e+f)\} \quad . \quad . \quad (6)$$

Now making use of the relation in equation (3) and using equations (4) and (5) we obtain, by putting the proper values of e, f, and g,

$$(1-\sigma)\frac{u}{r}+\sigma\left(\frac{du}{dr}+\frac{d\xi}{dx}\right)=(1-\sigma)\left(\frac{du}{dr}+r\frac{d^2u}{dr^2}\right)$$
$$+\sigma\left(\frac{du}{dr}+r\frac{d}{dr}\frac{d\xi}{dx}+\frac{d\xi}{dx}\right),$$

or transposing and dividing by r

$$(1-\sigma)\left(\frac{d^2u}{dr^2}+\frac{1}{r}\frac{du}{dr}-\frac{u}{r^2}\right)+\sigma\frac{d}{dr}\frac{d\xi}{dx}=0 \quad . \quad . \quad . \quad (7)$$

Assuming that the longitudinal stress R is constant throughout the section,

$$\frac{dR}{dr}=0,$$

and from (6)

$$(1-\sigma)\frac{d}{dr}\frac{d\xi}{dx}+\sigma\left(\frac{d^2u}{dr^2}+\frac{1}{r}\frac{du}{dr}-\frac{u}{r^2}\right)=0 \qquad . \quad . \quad (8)$$

From (7) and (8) we see that

$$\frac{d^2u}{dr^2}+\frac{1}{r}\frac{du}{dr}-\frac{u}{r^2}=0 \qquad . \quad . \quad . \quad . \quad . \quad (9)$$

and

$$\frac{d}{dr}\frac{d\xi}{dx}=0 \qquad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

Integrating (9)

$$\frac{du}{dr}+\frac{u}{r}=2C, \text{ a constant,}$$

or $$rdu+udr=2Crdr,$$

and again integrating $$ur=Cr^2+D$$

that is $$e=\frac{u}{r}=C+\frac{D}{r^2}$$

and $$f=\frac{du}{dr}=C-\frac{D}{r^2}$$

Integrating (10)

$$g=\frac{d\xi}{dx}=a, \text{ a constant.}$$

Suppose we are dealing with a single tube of a gun of radii r_{n-1} and r_n; then the radial stress varies from P_{n-1} at the interior to P_n at the exterior of the tube. As the tensional stresses are considered positive, the pressures must be negative.

Therefore from (5)

$$P_{n-1}-P_n=D\frac{M}{1+\sigma}\left(\frac{r_n^2-r_{n-1}^2}{r_{n-1}^2r_n^2}\right)$$

$$D=\frac{1+\sigma}{M}\frac{r_{n-1}^2r_n^2}{r_n^2-r_{n-1}^2}(P_{n-1}-P_n),$$

and by putting $R=0$ or to a constant in (6) and combining the result with (5) we obtain the other constants,

$$C=\frac{1-\sigma}{M}\frac{P_{n-1}r_{n-1}^2-P_nr_n^2}{r_n^2-r_{n-1}^2}$$

$$a=-\frac{2\sigma}{M}\frac{P_{n-1}r_{n-1}^2-P_nr_n^2}{r_n^2-r_{n-1}^2}.$$

Using these values in equations (4), (5), and (6) we find for any intermediate radius r that

$$T=\frac{P_{n-1}r_{n-1}^2-P_nr_n^2}{r_n^2-r_{n-1}^2}+\frac{r_{n-1}^2r_n^2}{r^2}\frac{P_{n-1}-P_n}{r_n^2-r_{n-1}^2}$$

$$=\frac{P_{n-1}(r^{-2}+r_n^{-2})-P_n(r_{n-1}^{-2}-r^{-2})}{r_{n-1}^{-2}-r_n^{-2}} \qquad . \quad . \quad (11)$$

$$P=\frac{r_{n-1}^2r_n^2}{r^2}\frac{P_{n-1}-P_n}{r_n^2-r_{n-1}^2}-\frac{P_{n-1}r_{n-1}^2-P_nr_n^2}{r_n^2-r_{n-1}^2}$$

$$=\frac{P_{n-1}(r^{-2}-r_n^{-2})+P_n(r_{n-1}^{-2}-r^{-2})}{r_{n-1}^{-2}-r_n^{-2}} \qquad . \quad . \quad (12)$$

$$R=0 \text{ or a constant} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$$

From the last equation of (2) it will be seen that

$$T+P=\frac{1}{\sigma}(R-Mg), \text{ a constant.}$$

Therefore in the same hoop, P being of negative sign,

$$T_n-P_n=T-P \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

Suppose the radii of the barrel to be r_0 and r_1, of the superimposed hoop r_1 and r_2, and of the n^{th} hoop r_{n-1} and r_n. Then from (12) the external pressure of the n^{th} hoop is

$$P_n=r_{n-1}^2\frac{P_{n-1}-P_n}{r_n^2-r_{n-1}^2}-\frac{P_{n-1}r_{n-1}^2-P_nr_n^2}{r_n^2-r_{n-1}^2},$$

and from (11) the internal tension of this hoop is

$$T_{n-1}=\frac{P_{n-1}r_{n-1}^2-P_nr_n^2}{r_n^2-r_{n-1}^2}+r_n^2\frac{P_{n-1}-P_n}{r_n^2-r_{n-1}^2}.$$

Adding, we find

$$T_{n-1}+P_n=(P_{n-1}-P_n)\frac{r_n^2+r_{n-1}^2}{r_n^2-r_{n-1}^2}.$$

Therefore the pressure between the n^{th} hoop and the $(n-1)^{th}$ hoop is

$$P_{n-1}=\frac{r_n^2-r_{n-1}^2}{r_n^2+r_{n-1}^2}(T_{n-1}+P_n)+P_n \qquad . \quad . \quad (15)$$

In the same way the pressure between the $(n-1)^{th}$ and $(n-2)^{th}$ hoops is

$$P_{n-2}=\frac{r_{n-1}^2-r_{n-2}^2}{r_{n-1}^2+r_{n-2}^2}(T_{n-2}+P_{n-1})+P_{n-1} \qquad . \quad . \quad (16)$$

So that when P_n and the tensions T_{n-1}, T_{n-2} . . . are known, the other pressures can be found. It is usual in gun construction to consider that the proof tension of the barrel should not exceed 15 tons per square inch, and of the outer hoops 18 tons per square inch. If the n^{th} hoop is the exterior hoop then $P_n=0$, if we neglect the atmospheric pressure.

The stress obtained by (15) is called the *Firing stress*, as it is due to the pressure P_0 of the powder gases produced by the discharge of the gun, P_0 varying for different positions along the bore (GUNNERY: § *Interior Ballistics*). In order to obtain the full benefit of the hoop system it will be seen that a certain pressure, to be obtained by shrinkage, should exist at the common surface of each pair of hoops; this is called the *initial stress* or *stress of repose*. Considering the gun a homogeneous solid block of steel, *i.e.*, by putting $n=1$ in (15) the powder pressure P_0 will produce the *powder stress;* and the following relation exists:—

$$\text{Initial stress}+\text{powder stress}=\text{firing stress} \quad . \quad . \quad (17)$$

The method of working will best be seen by a practical example. Take, for instance, a section across the chamber of a 4·7-inch Q.-F. gun, in which the diameter of the chamber is 5 inches, that of the barrel 8·2 inches, and the external diameter of the jacket 15 inches.

$$\text{Here } r_0=2{\cdot}5\ ;\ r_1=4{\cdot}1\ ;\ \text{and } r_2=7{\cdot}5$$
$$T_0=15\ ;\ T_1=18\ ;\ \text{and } P_2=0.$$

From (15) we have for the firing stress

$$P_1=\frac{(7{\cdot}5)^2-(4{\cdot}1)^2}{(7{\cdot}5)^2+(4{\cdot}1)^2}\times 18=9{\cdot}72 \text{ tons per square inch.}$$

$$P_0=\frac{(4{\cdot}1)^2-(2{\cdot}5)^2}{(4{\cdot}1)^2+(2{\cdot}5)^2}\times(15+9{\cdot}72)+9{\cdot}72=21 \text{ tons per square inch.}$$

By (14) we can obtain the tension $T_n{}^1$ of the outer fibres of the hoops, thus

$$T_2{}^1=P_2+T_1-P_1=18-9{\cdot}72=8{\cdot}28 \text{ tons,}$$
$$\text{and } T_1{}^1=P_1+T_0-P_0=9{\cdot}72+15-21=3{\cdot}72 \text{ tons.}$$

For the powder stress (11) and (12) may be used by making $n=1$ and $p_1=0$, then

$$t_0=\frac{(7{\cdot}5)^2+(2{\cdot}5)^2}{(7{\cdot}5)^2-(2{\cdot}5)^2}\times 21=26{\cdot}25 \text{ tons,}$$

$$t_2{}^1=26{\cdot}25-21=5{\cdot}25 \text{ tons,}$$

for a radius $r=4{\cdot}1$ inches

$$p=6{\cdot}32 \text{ tons and } t_1=11{\cdot}57 \text{ tons.}$$

Subtracting the powder stress from the firing stress we obtain the initial stress, which can be seen at a glance from the following table:—

		Tensions.			Pressures.		
	At Radius.	Firing Stress.	Powder Stress.	Initial Stress.	Firing Stress.	Powder Stress.	Initial Stress.
Barrel	$r_0=2{\cdot}5$	15·0	26·25	−11·25	21·0	21·0	0
	$r_1=4{\cdot}1$	3·72	11·57	−7·85	9·72	6·32	3·4
Jacket	$r_1=4{\cdot}1$	18·0	11·57	6·43	9·72	6·32	3·4
	$r_2=7{\cdot}5$	8·28	5·25	3·03	0	0	0

Figure 16, A shows the stress drawn to scale.

Denoting by u^1_{n-1} and u_{n-1} the radial displacement, from the unstrained position, of the outer and inner circumferential fibres of a tube and the superimposed hoop respectively due to shrinkage, the external radius $r_{n-1}+u_{n-1}{}^1$ of the tube will be diminished by $u_{n-1}{}^1$ and the internal radius $r_{n-1}-u_{n-1}$ of the hoop will be increased by u_{n-1}.

Since the shrinkage S is defined as the excess of the external diameter of a tube over the internal diameter of the hoop before shrinkage when both are in the cold state

$$\tfrac{1}{2}S=(r_{n-1}+u_{n-1}{}^1)-(r_{n-1}-u_{n-1})=u_{n-1}{}^1+u_{n-1}$$

As u_{n-1} denotes an extension it is considered positive in sign, and since u^1_{n-1} denotes a compression it is negative. From (2) we have

$$Me=\ M\frac{u_{n-1}}{r_{n-1}}=T_{n-1}-\sigma(P_{n-1}+R)$$

$$-Me=-M\frac{u^1_{n-1}}{r_{n-1}}=T^1_{n-1}-\sigma(P_{n-1}+R).$$

Therefore subtracting

$$M(u_{n-1}+u_{n-1}{}^1)=(T_{n-1}-T_{n-1}{}^1)r_{n-1},$$

or, denoting the shrinkage between the $(n-1)^{th}$ and n^{th} hoops by ${}_{n-1}S_n$ we find that

$${}_{n-1}S_n=(T_{n-1}-T_{n-1}{}^1)\frac{2r_{n-1}}{M} \qquad . \quad . \quad . \quad (17)$$

From (14)

$$T_{n-1} - T_{n-1}{}^1 = T_{n-1} - T_{n-2} + P_{n-2} - P_{n-1},$$

and consequently

$$_{n-1}S_n = \left\{T_{n-1} - T_{n-2} + \frac{r_{n-1}^2 - r_{n-2}^2}{r_{n-1}^2 + r_{n-2}^2}(T_{n-2} + P_{n-1})\right\}\frac{2r_{n-1}}{M} \quad . \quad (18)$$

Where M can be taken as 12,500 tons per square inch for gun steel. (See Unwin's *Testing of Materials of Construction*, p. 249.)

In wire guns, we may regard the tube on which the wire is wound, as so large, in comparison with the thickness of the wire, that the compression of the concave surface of the wire and the extension of its convex surface may be neglected without sensible error. We may also neglect any consideration of longitudinal stress in the wire coils.

It is assumed that in the firing stress the tension T, usually taken at from 25 to 30 tons per square inch, is uniform throughout the thickness of the wiring. If the wire is wound direct on the barrel and is covered by a jacket, then r_0, r_1 are the radii of the barrel, r_1, r_2 are the radii of the internal and external layer of wire, and r_2, r_3 the radii of the jacket. Then for the firing stress in the wire we have—

$$T(r_2 - r) = Pr - P_2 r_2 \quad . \quad . \quad . \quad (19)$$

or

$$T(r - r_1) = P_1 r_1 - Pr \quad . \quad . \quad . \quad (20)$$

The initial tensions of the wire are arranged so that T is uniform when the gun is fired, and we have now to determine what must be the winding tensions to produce these conditions.

Denote by θ the winding tension, by ϕ the initial tension, and by ω the pressure at any radius r. It is assumed that M is uniform for the gun steel and wire, and that θ, at any radius r, is equal to ϕ increased by the circumferential stress, due to the initial radial pressure ω, of the superincumbent layers, acting on the portion of the wire coil and barrel between the radii r_0 and r. Thus from equation (15) by putting $n=1$ and $P_0=0$, and considering the barrel and wire homogeneous

$$\theta = \phi + \omega\frac{r^2 + r_0^2}{r^2 - r_0^2} \quad . \quad . \quad . \quad . \quad (21)$$

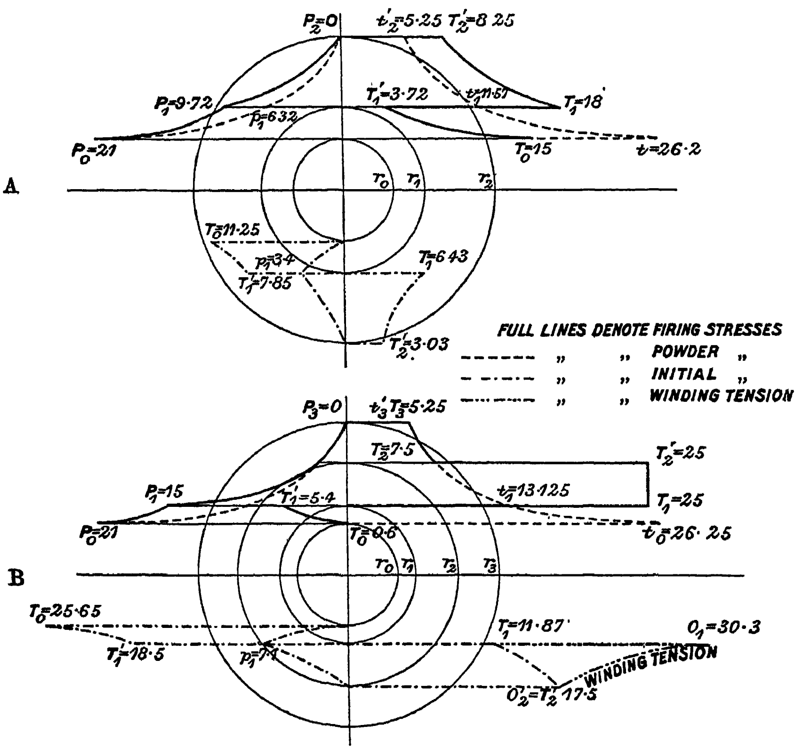

Fig. 16.

From (17), (11), and (12), P_0 being now the powder pressure—

$$\phi = T = P_0\frac{r_0^2}{r^2} \cdot \frac{r_3^2 + r^2}{r_3^2 - r_0^2} \quad . \quad . \quad . \quad (22)$$

$$\omega = P - P_0\frac{r_0^2}{r^2} \cdot \frac{r_3^2 - r^2}{r_3^2 - r_0^2} \quad . \quad . \quad . \quad (23)$$

By means of these equations and by (19) we find that the expression (21) reduces to

$$\theta = \frac{E}{r} + \frac{F}{r - r_0} + \frac{G}{r + r_0}$$

where

$$E = -(T + P_2)r_2$$
$$F = (T + P_2)r_2 - (T + P_0)r_0$$
$$G = (T + P_2)r_2 + (T + P_0)r_3.$$

To compare with the previous example, we will calculate the stresses in a 4·7 Q.-F. wire gun, consisting of a barrel, intermediate layer of wire, and jacket.

Here $r_0 = 2{\cdot}5$, $r_1 = 3{\cdot}75$, $r_2 = 5{\cdot}5$, $r_3 = 7{\cdot}5$;

the tension T_1 to $T_2{}^1$ of the wire = 25 tons per square inch, suppose.

Take $P_0 = 21$ tons per square inch and consider that the jacket fits tightly over the wire, but has no shrinkage. Then for the firing stresses we have from (12)

$$P_2 = 2{\cdot}25 \text{ tons},$$

and from (19) and (20) $T_1(r_2 - r_1) = P_1 r_1 - P_2 r_2$

$$P_1 = 14{\cdot}97, \text{ say } 15 \text{ tons};$$

from (15) we can obtain T_0 and T_2 since we know P_0, P_2, and P_2

$$T_0 = 0{\cdot}6 \text{ tons}, \ T_2 = 7{\cdot}5 \text{ tons}.$$

From (11) we find

$$T_1{}^1 = -5{\cdot}4 \text{ tons (a compression) and } T_3{}^1 = 5{\cdot}25 \text{ tons}.$$

The powder stress can be obtained in the same way as in the previous example, and so also the initial stress; therefore tabulating:—

	At Radius	Tensions. Firing Stress.	Tensions. Powder Stress.	Tensions. Initial Stress.	Pressures. Firing Stress.	Pressures. Powder Stress.	Pressures. Initial Stress
Barrel	$r_0 = 2{\cdot}5$	0·6	26·25	−25·65	21·0	21·0	0
	$r_1 = 3{\cdot}75$	−5·4	13·125	−18·525	15·0	7·875	7·125
Wire	$r_1 = 3{\cdot}75$	25·0	13·125	11·875	15·0	7·875	7·125
	$r_2 = 5{\cdot}5$	25·0	7·5	17·5	2·25	2·25	0
Jacket	$r_2 = 5{\cdot}5$	7·5	7·5	0	2·25	2·25	0
	$r_3 = 7{\cdot}5$	5·25	5·25	0	0	0	0

For the winding tension of the wire

$$E = -149{\cdot}875 \ ; \ F = 34{\cdot}875 \ ; \ G = 264{\cdot}875 \ ;$$

so that calculating θ we find that the winding tension must commence 30·3 tons per square inch and finish off at 17·5 tons per square inch. It will be noticed that the finishing-off tension is the same as the initial tension which would be expected.

Fig. 16, B shows these stresses.

Professor Greenhill has put these formulas, both for the built-up and wire-wound guns, into an extremely neat and practical geometrical form, which could be used instead of the arithmetical processes; for these see the *Text-Book of Gunnery*, *Treatise of Service Ordnance*, and *Journal of the United States Artillery*, vol. iv.

In England, as we have before mentioned, the longitudinal stress at the breech end of the gun is provided for by the breech piece; or, in guns where this is absent, by the jacket. Its amount is easily calculated on the hypothesis of uniform stress throughout the thickness of the breech piece or jacket.

If r_0 is the largest radius of the gun chamber, P_0 the maximum powder pressure, and the radii of the breech piece or jacket r_1 and r_2, then the tension in tons per square inch

$$T = \frac{2\pi P_0 r_0^2}{2\pi(r_2^2 - r_1^2)} = P_0\frac{r_0^2}{r_2^2 - r_1^2}.$$

Gunmakers usually arrange that a large factor of safety is observed in providing for this longitudinal stress; and in the larger calibres of guns both the breech piece and jacket may be available for longitudinal strength; but even in this case the jacket is best considered as an auxiliary only, as, owing to the necessary connexions between these two portions, it is possible the jacket may not be taking its full share of stress.

The screw thread of the breech screw and of the breech opening must be so proportioned as to provide for a similar strength; but in many modern B.-L. guns fitted with De Bange obturation the diameter of the seating at the breech opening can be made just large enough to admit the projectile freely. As this would generally be considerably smaller than the maximum diameter of the chamber, a less area is exposed to the gas pressure, and consequently less thread section is required.

(A. G. H.)

GUNNERY OR BALLISTICS.

BALLISTICS, the science of throwing warlike missiles or projectiles, is now divided into two parts: *Exterior Ballistics*, in which the motion of the projectile is considered after it has received its initial impulse, when the projectile is moving freely under the influence of gravity and the resistance of the air, and it is required to determine the circumstances so as to hit a certain object, with a view to its destruction or perforation; and *Interior Ballistics*, in which the pressure of the powder-gas is analysed in the bore of the gun, and the investigation is carried out of the requisite charge of powder to secure the initial velocity of the projectile; also including the calculation of the strength of the various parts of the gun required to withstand the pressure at all parts of the bore.

I. Exterior Ballistics.

In the ancient theory due to Galileo, the resistance of the air is ignored, and, as shown in ordinary treatises on Dynamics, the trajectory is now a *parabola*. But this theory is very far from being of practical value for most purposes of gunnery; so that a first requirement is an accurate experimental knowledge of the resistance of the air to the projectiles employed, at all velocities useful in artillery. The theoretical assumptions of Newton and Euler (*hypotheses magis mathematicæ quam naturales*) of a resistance varying as some simple power of the velocity, for instance, as the square or cube of the velocity (the quadratic or cubic law), lead to results of great analytical complexity, and are useful only for provisional extrapolation at high or low velocities, pending further experiment.

The foundation of our knowledge of the resistance of the air, as employed in the construction of Ballistic Tables, is the series of experiments carried out between 1867 and 1879 by the Rev. F. Bashforth, B.D. (*Report on the Experiments made with the Bashforth Chronograph*, &c., 1865–1870; *Final Report*, &c., 1878–1880; *The Bashforth Chronograph*, Cambridge, 1890). According to these experiments, the resistance of the air can be represented by no simple mathematical law over a large range of velocity. Abandoning therefore all *à priori* theoretical assumption, Bashforth set to work to measure experimentally the velocity of shot and the resistance of the air by means of equidistant electric screens furnished with vertical threads or wire, and by a chronograph which measured the instants of time at which the screens were cut by a shot flying nearly horizontally. Formulæ of the *Calculus of Finite Differences* enable us from the chronograph records to infer the velocity and retardation of the shot, and thence the resistance of the air. (For practical details refer to the article CHRONOGRAPH.)

As a first result of the experiments it was found that the resistance of similar shot was proportional, at the same velocity, to the surface, or cross section, or square of the diameter. The resistance R can thus be divided into two factors, one of which is d^2, where d denotes the diameter of the shot in inches, and the other factor is denoted by p or $f(v)$, where p is the resistance in pounds at the same velocity to a similar 1-inch projectile; thus

$$R = d^2p = d^2f(v),$$

and the value of p, or $f(v)$, for velocities ranging from 100 to 2800 feet per second (f/s) is given in the second column of the extract from the abridged Ballistic Table.

These values of p refer to a standard density of the air, of 534·22 grains per cubic foot, which is the density of dry air at sea-level in the latitude of Greenwich, at a temperature of 62° F. and a barometric height of 30 inches.

But in consequence of the humidity of the climate of England it is better to suppose the air to be (on the average) two-thirds saturated with aqueous vapour, and then the standard temperature will be reduced to 60° F., so as to secure the same standard density; the density of the air being reduced perceptibly by the presence of the aqueous vapour.

It is further assumed, as the result of experiment, that the resistance is proportional to the density of the air; so that if the standard density changes from unity to any other relative density denoted by τ, then

$$R = \tau d^2p,$$

and τ is called the *coefficient of tenuity*.

The factor τ becomes of importance in long-range high-angle fire, where the shot reaches the higher attenuated strata of the atmosphere; on the other hand, we must take $\tau =$ about 800, in calculations of shooting under water.

The resistance of the air is considerably reduced in modern projectiles by giving them a greater length and a sharper point, and by the omission of projecting studs, and a factor κ, called the *coefficient of shape*, is introduced to allow for this change.

For projectiles in which the ogival head is struck with a radius of 2 diameters, Bashforth puts $\kappa = 0{\cdot}975$; on the other hand, for flat-headed projectiles, as required at proof-butts, $\kappa = 1{\cdot}8$, say 2 on the average.

For spherical shot κ is not constant, and a separate ballistic table must be constructed; but κ may be taken as 1·7 on the average.

Lastly, to allow for the superior centring of the shot obtainable with the breech-loading system, Bashforth introduces a factor σ, called the *coefficient of steadiness*.

This steadiness may vary during the flight of the projectile, as the shot may be unsteady for some distance after leaving the muzzle, afterwards steadying down, like a spinning-top. Again, σ may increase as the gun wears out, after firing a number of rounds.

Collecting all the coefficients, τ, κ, σ, into one, we put

$$(1) \qquad R = nd^2p = nd^2f(v)$$

where

$$(2) \qquad n = \tau\kappa\sigma,$$

and n is called the *coefficient of reduction*.

By means of a well-chosen value of n, determined by a few experiments, it is possible, with the most recent designs, to utilize Bashforth's experimental results carried out with old-fashioned projectiles, pending further experiments. For instance, $n = 0{\cdot}8$ is considered a good average for the modern rifle bullet.

Starting with the experimental values of p, for a standard projectile, fired under standard conditions in air of standard density, we proceed to the construction of the Ballistic Tables; and first determine the time t in seconds required for the velocity of a shot, d inches in diameter and weighing w pounds, to fall from any initial velocity V f/s to any final velocity v f/s.

If r denotes the retardation of the shot, in f/s², due to the resistance of R pounds, then by Newton's *Second Law of Motion*, "Change of Motion is proportional to the Impressed Force."

$$(3) \qquad \frac{r}{g} = \frac{R}{w} = \frac{nd^2}{w}p,$$

since r varies as R, and $r = g$ when $R = w$.

If Δv denotes the loss of velocity in the small interval of time Δt,

$$(4) \qquad \frac{\Delta v}{\Delta t} = \text{average retardation in the interval } \Delta t$$
$$= r = \frac{R}{w}g = \frac{nd^2}{w}gp$$

where p denotes the average value in the interval; and therefore

$$(5) \qquad \Delta t = \frac{w}{nd^2}\frac{\Delta v}{gp}.$$

We put

$$(6) \qquad \frac{w}{nd^2} = C,$$

and call C the *ballistic coefficient* (driving-power) of the shot; so that

$$(7) \qquad \Delta t = C\frac{\Delta v}{gp};$$

and now if t changes to T for the standard projectile for which $C = 1$,

$$(8) \qquad \Delta t = C\Delta T,$$

where

$$(9) \qquad \Delta T = \frac{\Delta v}{gp}.$$

Since p is tabulated as $f(v)$, a function of v, the velocity v is taken as the argument of the Ballistic Table; starting with the lowest experimental value, say $v = 400$, the change in velocity Δv is taken constantly as 10, and the average value of p in each interval of velocity between 400, 410, 420, . . . is multiplied by g and divided into $\Delta v = 10$, to obtain the corresponding value of ΔT; the sum of these values of ΔT is afterwards made, by an arithmometer, and entered in the column under T.

The number T is also denoted by T(v), and now

$$(10) \qquad T(V) - T(v)$$

is the time taken by the standard projectile for the velocity to fall from V to v f/s; while

$$(11) \qquad t = C\{T(V) - T(v)\}$$

is the number of seconds occupied by a projectile whose ballistic coefficient is C, between the same limits of velocity, V and v.

Next let Δs denote the number of feet of advance in the time Δt; then

$$(12) \qquad \Delta s = v\Delta t,$$

and if s changes to S for the standard projectile,

$$(13) \qquad \Delta S = v\Delta T,$$

where v denotes the mean velocity in the interval; and ΔS can be calculated with sufficient accuracy from ΔT by taking the mean velocity in the intervals as 415, 425, 435. . . .

These differences ΔS are entered in the corresponding column of the table; and their sum, obtained by the arithmometer, is entered in the column headed S.

The number S, also denoted by S(v), is such that

$$(14) \qquad S(V) - (S)v$$

is the number of feet advanced horizontally by the standard projectile, while the velocity falls from V to v f/s; and

$$(15) \qquad s = C[S(V) - S(v)]$$

is the number of feet of advance of any other projectile whose ballistic coefficient is C, between the same limits of velocity, V and v.

To save the trouble of proportional parts required when the velocity proceeds by increments of 10, Bashforth has provided Ballistic Tables which give by interpolation the values of T and S for every unit of velocity, in the region useful in artillery. A third table, due to Mr W. D. Niven, F.R.S., Director of Naval Studies, Greenwich, called the *degree* table, determines the change of direction of motion of the shot while the velocity changes from V to v, the shot flying nearly horizontally.

To explain the theory of this table, suppose the tangent at the point of the trajectory, where the velocity is v, to make an angle i radians with the horizon.

Then, resolving normally in the trajectory, and supposing the resistance of the air to act tangentially,

$$(16) \qquad v\frac{di}{dt} = g\cos i,$$

where di denotes the infinitesimal *decrement* of i in the infinitesimal increment of time dt.

In problems of Direct Fire, where the trajectory is flat enough for $\cos i$ to be undistinguishable from unity, equation (16) becomes

$$(17) \qquad v\frac{di}{dt} = g, \text{ or } \frac{di}{dt} = \frac{g}{v};$$

so that we can put

$$(18) \qquad \frac{\Delta i}{\Delta t} = \frac{g}{v},$$

if v denotes the mean velocity during the small finite interval of time Δt, during which the direction of motion of the shot changes through Δi radians.

If the inclination or change of inclination in degrees is denoted by δ or $\Delta\delta$,

$$(19) \qquad \frac{\delta}{180} = \frac{i}{\pi},$$

so that

$$(20) \qquad \Delta\delta = \frac{180}{\pi}\Delta i = \frac{180g}{\pi}\frac{\Delta t}{v};$$

and if δ and i change to D and I for the standard projectile,

$$(21) \qquad \Delta I = g\frac{\Delta T}{v},$$

$$(22) \qquad \Delta D = \frac{180g}{\pi}\frac{\Delta T}{v}.$$

The differences ΔD are thus calculated, while the values of D are obtained by summation with the arithmometer; and they are entered in their respective columns.

For some purposes it is preferable to retain the circular measure, i radians, as being undistinguishable in Direct Fire from $\sin i$ and $\tan i$; and now the differences ΔI and the sum I are calculated and entered in their columns.

The last function A, called the *altitude function*, will be explained when High Angle Fire is considered (p. 175).

The annexed scheme of computation shows the method employed, using four-figure logarithms; and when the significant figures are reduced to three, the work can be shortened still further by the use of the Slide Rule.

When the values of p are revised in accordance with the results of new experiments, a recomputation of the Ballistic Tables in this manner will have to be carried out.

CALCULATION OF A BALLISTIC TABLE.

v		1600-1610.	1610-1620.	1620-1630.
p		11·48	11·60	11·72

In the calculation of Range Tables for *Direct Fire*, defined officially as "fire from guns with full charges at elevations not exceeding 15°," the vertical component of the resistance of the air may be ignored as insensible, and

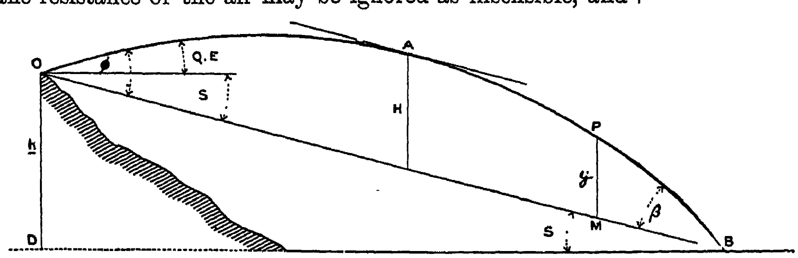

Fig. 1.

the actual velocity and its horizontal component, or component parallel to the line of sight, are undistinguishable.

The equations of motion are now, the co-ordinates x and y being measured in feet,

$$\frac{d^2x}{dt^2} = -r = -\frac{gp}{C}. \tag{23}$$

$$\frac{d^2y}{dt^2} = -g. \tag{24}$$

The first equation leads, as before, to

$$t = C\{T(V) - T(v)\}. \tag{25}$$

$$x = C\{S(V) - S(v)\}. \tag{26}$$

The integration of (24) gives

$$\frac{dy}{dt} = \text{constant} - gt = g(\tfrac{1}{2}T - t), \tag{27}$$

if T denotes the whole time of flight from O to the point B (Fig. 1), where the trajectory cuts the line of sight; so that $\frac{1}{2}$T is the time to the vertex A, where the shot is flying parallel to OB.

Integrating (27) again,

$$y = g(\tfrac{1}{2}Tt - \tfrac{1}{2}t^2) = \tfrac{1}{2}gt(T - t)\,; \tag{28}$$

and denoting T − t by t', and taking $g = 32f/s^2$,

$$y = 16tt', \tag{29}$$

Colonel Sladen's formula, employed in plotting ordinates of a trajectory.

At the vertex A, where $y = H$, we have $t = t' = \frac{1}{2}T$, so that

$$H = \tfrac{1}{8}gT^2, \tag{30}$$

which for practical purposes, taking $g = 32$, is replaced by

$$H = 4T^2, \text{ or } (2T)^2. \tag{31}$$

Thus if the time of flight of a shell is 5 seconds, the height of the vertex of the trajectory is about 100 feet; and if the fuse is set to burst the shell one-tenth of a second short of its impact at B, the height of the burst is 7·84, say 8 feet.

The line of sight Ox, considered horizontal in Range Table results, may be slightly inclined to the horizon, as in shooting up or down moderate slopes, without appreciable modification of (25) and (26), and y or PM is still drawn vertically to meet OB in M.

Given the ballistic coefficient C, the initial velocity V, and a range of R yards or X = 3R feet, the final velocity v is first calculated from (26) by

(32) $$S(v) = S(V) - \frac{X}{C},$$

and then the time of flight T by

(33) $$T = C\{T(V) - T(v)\}.$$

Denoting the angles of departure and descent, measured in degrees and from the line of sight OB, by ϕ and β, the total deviation in the range OB is (Fig. 1)

(34) $$\delta = \phi + \beta = C\{D(V) - D(v)\}.$$

To share the δ between ϕ and β, the vertex A is taken as the point of *half-time* (and therefore beyond *half-range*, because of the continual diminution of the velocity), and the velocity v_o at A is calculated from the formula

(35) $$T(v_o) = T(V) - \frac{\frac{1}{2}T}{C} = \tfrac{1}{2}\{T(V) + T(v)\};$$

and now the degree table gives

(36) $$\phi = C\{D(V) - D(v_o)\},$$

(37) $$\beta = C\{D(v_o) - D(v)\}.$$

This value of ϕ is the tangent elevation (T. E.); the quadrant elevation (Q. E.) is ϕ − S, where S is the angular depression of the line of sight OB; and if O is h feet vertical above B, the angle S in minutes at a range of R yards is given by

(38) $$\sin S = \frac{h}{3R}$$

or, for small angle, expressed in minutes,

(39) $$S = 1146\frac{h}{R}.$$

So also the angle β must be increased by S to obtain the angle at which the shot strikes a horizontal plane, the water, for instance.

The following is a specimen of the calculations required in the compilation of a Range Table for moderate ranges of Direct Fire:—a 6-inch gun has been selected, with increments of range of 500 yards, reaching up to 2000 yards; the intermediate hundreds of yards can be interpolated, and the results tabulated in the ordinary form of a Range Table (of which a short extract is given), in which vertical columns give the values of v, t, ϕ, β, &c., corresponding to every hundred yards of range. The discrepancies between the calculated and tabulated results will serve to show the influence of a slight change in the coefficient of reduction n and the muzzle velocity V.

The Abridged Ballistic Table has been employed, of which the extract given above covers the extent of velocity required; to avoid the trouble of proportional parts required for units of velocity with the Abridged Table, extended tables are given in Text-Books of Gunnery, but these are too long for insertion here.

A Slide Rule can be used for the computations, instead of four-figure logarithms, with ample accuracy for practical purposes.

Calculation of a Range Table for 6-inch Gun.

High Angle and Curved Fire.—"High Angle Fire," as defined officially, "is fire at elevations greater than 15°," and "Curved Fire is fire from howitzers at all angles of elevation not exceeding 15°." In these cases the curvature of the trajectory becomes considerable, and the methods employed in Direct Fire must be modified; the method generally employed is due to Colonel Siacci of the Italian Artillery.

Starting with the exact equations of motion in a resisting medium

$$(40) \qquad \frac{d^2x}{dt^2} = -r\cos i = -r\frac{dx}{ds},$$

$$(41) \qquad \frac{d^2y}{dt^2} = -r\sin i - g = -r\frac{dy}{ds} - g,$$

and eliminating r,

$$(42) \qquad \frac{dx}{dt}\frac{d^2y}{dt^2} - \frac{dy}{dt}\frac{d^2x}{dt^2} = -g\frac{dx}{dt};$$

and this, in conjunction with

$$(43) \qquad \tan i = \frac{dy}{dx} = \frac{dy}{dt}\Big/\frac{dx}{dt}.$$

$$(44) \qquad \sec^2 i\frac{di}{dt} = \left(\frac{dx}{dt}\frac{d^2y}{d^2t} - \frac{dy}{dt}\frac{d^2x}{dt^2}\right)\Big/\left(\frac{dx}{dt}\right)^2,$$

reduces to

$$(45) \qquad \frac{di}{dt} = -\frac{g}{v}\cos i, \text{ or } \frac{d\tan i}{dt} = -\frac{g}{v\cos i},$$

the equation obtained, as in (16), by resolving normally in the trajectory, but di now denoting the *increment* of i in the increment of time dt.

Denoting $\frac{dx}{dt}$, the horizontal component of the velocity, by q, so that

$$(46) \qquad v\cos i = q,$$

equation (40) becomes

$$(47) \qquad \frac{dq}{dt} = -r\cos i,$$

and therefore

$$(48) \qquad \frac{dq}{di} = \frac{dq}{dt}\frac{dt}{di} = \frac{rv}{g},$$

by reason of (45).

It is convenient to express p as a function of v in the notation

$$(49) \qquad p = f(v),$$

so that

$$(50) \qquad r = g\frac{f(v)}{C},$$

and now

$$(51) \qquad \frac{dq}{di} \text{ or } \frac{dv\cos i}{di} = \frac{vf(v)}{C},$$

an equation connecting $v = q\sec i$, or q and i.

Now

$$(52) \qquad \frac{dt}{dq} = -C\frac{\sec i}{gf(q\sec i)},$$

and multiplying by $\frac{dx}{dt}$ or q,

$$(53) \qquad \frac{dx}{dq} = -C\frac{q\sec i}{gf(q\sec i)},$$

and multiplying by $\frac{dy}{dx}$ or $\tan i$,

$$(54) \qquad \frac{dy}{dq} = -C\frac{q\sec i\tan i}{gf(q\sec i)};$$

also

$$(55) \qquad \frac{di}{dq} = C\frac{1}{q\sec i f(q\sec i)}$$

$$(56) \qquad \frac{d\tan i}{dq} = C\frac{\sec i}{qf(q\sec i)},$$

from which the values of t, x, y, i, and $\tan i$ are given by integration with respect to q, when $\sec i$ is given as a function of q by means of (48).

Now these integrations are quite intractable, even for very simple mathematical assumptions of the function $f(v)$, say the quadratic or cubic law, $f(v) = kv^2$, or kv^3.

But, as originally pointed out by Euler, the difficulties can be turned if we notice that in the ordinary trajectories of practice the quantities i, $\cos i$, and $\sec i$ vary so slowly that they may be replaced by their *mean* values η, $\cos\eta$, and $\sec\eta$; especially if the trajectory, when considerable, is divided up in the calculations into arcs of small curvature, the curvature of an arc being defined as the angle between the tangents or normals at the ends of the arc.

Replacing then the angle i on the right-hand side of equations (52)–(56) by some mean value η, we introduce Siacci's pseudo-velocity u defined by

$$(57) \qquad u = q\sec\eta,$$

so that u is a quasi-component parallel to the mean direction of the tangent, say the direction of the chord of the arc.

Integrating from any initial pseudo-velocity U,

$$(58) \qquad t = C\int_u^U \frac{du}{gf(u)},$$

$$(59) \qquad x = C\cos\eta\int\frac{u\,du}{gf(u)},$$

$$(60) \qquad y = C\sin\eta\int\frac{u\,du}{gf(u)};$$

and supposing the inclination i to change from ϕ to θ radians over the arc,

$$(61) \qquad \phi - \theta = C\cos\eta\int\frac{du}{uf(u)},$$

$$(62) \qquad \tan\phi - \tan\theta = C\sec\eta\int\frac{du}{uf(u)}.$$

But according to the definition of the functions T, S, I, and D of the Ballistic Table, employed for Direct Fire, with u written for v,

$$(63) \qquad \int_u^U\frac{du}{gf(u)} = \int\frac{du}{gp} = T(U) - T(u),$$

$$(64) \qquad \int\frac{u\,du}{gf(u)} = S(U) - S(u),$$

$$(65) \qquad \int\frac{du}{uf(u)} = I(U) - I(u);$$

and therefore

$$(66) \qquad t = C[T(U) - T(u)]$$

$$(67) \qquad x = C\cos\eta[S(U) - S(u)]$$

$$(68) \qquad y = C\sin\eta[S(U) - S(u)]$$

$$(69) \qquad \phi - \theta = C\cos\eta[I(U) - I(u)]$$

$$(70) \qquad \tan\phi - \tan\theta = C\sec\eta[I(U) - I(u)],$$

while, expressed in degrees,

$$(71) \qquad \phi^\circ - \theta^\circ = C\cos\eta[D(U) - D(u)].$$

These (66)–(71) are Siacci's equations, slightly modified by General Mayevski; and now in the numerical applications to High Angle Fire we can still employ the Ballistic Table for Direct Fire.

It will be noticed that η cannot be exactly the same mean angle in all these equations; but if η is the same in (67) and (68),

$$(72) \qquad \frac{y}{x} = \tan\eta,$$

so that η is the inclination of the chord of the arc of the trajectory, as in Niven's method of calculating trajectories (*Proc. R. S.*, 1877); but this method requires η to be known with accuracy, as 1% variation in η causes more than 1% variation in $\tan\eta$.

The difficulty is avoided by the use of Siacci's altitude-function A or A(u), by which y/x can be calculated without introducing $\sin\eta$ or $\tan\eta$, but in which η occurs only in the form $\cos\eta$ or $\sec\eta$, which varies very slowly for moderate values of η, so that η need not be calculated with any great regard for accuracy, the arithmetic mean $\frac{1}{2}(\phi + \theta)$ of ϕ and θ being near enough for η over any moderate arc $\phi - \theta$.

Now taking equation (70), and replacing $\tan\theta$, as a variable final tangent of an angle, by $\tan i$ or $\frac{dy}{dx}$,

$$(73) \qquad \tan\phi - \frac{dy}{dx} = C\sec\eta\Big[I(U) - I(u)\Big]$$

and integrating with respect to x over the arc considered,

$$(74) \qquad x\tan\phi - y = C\sec\eta\left[xI(U) - \int_0^x I(u)dx\right].$$

But

$$(75) \qquad \int_0^x I(u)dx = \int_U^u I(u)\frac{dx}{du}du$$
$$= C\cos\eta\int_u^U I(u)\frac{u\,du}{gf(u)}$$
$$= C\cos\eta[A(U) - A(u)]$$

in Siacci's notation; so that the altitude-function A must be calculated by summation from the finite differences,

(76) $$\Delta \mathrm{A} = \mathrm{I}(u)\frac{u\Delta u}{gp} = \mathrm{I}(u)\Delta \mathrm{S},$$

as shown already in the specimen computation of the Ballistic Table.

Dividing again by x, as given in (67),

(77) $$\tan\phi - \frac{y}{x} = \mathrm{C}\sec\eta\left[\mathrm{I}(\mathrm{U}) - \frac{\mathrm{A}(\mathrm{U}) - \mathrm{A}(u)}{\mathrm{S}(\mathrm{U}) - \mathrm{S}(u)}\right]$$

from which y/x can be calculated, and thence y.

In the application of Siacci's method to the calculation of a trajectory in High Angle Fire by successive arcs of small curvature, starting at the beginning of an arc at an angle ϕ with velocity v_ϕ, the curvature of the arc $\phi - \theta$ is first settled upon, and now

(78) $$\eta = \tfrac{1}{2}(\phi + \theta)$$

is a good first approximation for η.

Now calculate the pseudo-velocity u_ϕ from

(79) $$u_\phi = v_\phi \cos\phi \sec\eta,$$

and then, from the given values of ϕ and θ, calculate u_θ from either of the formulæ of (70) or (71),

(80) $$\mathrm{I}(u_\theta) = \mathrm{I}(u_\phi) - \frac{\tan\phi - \tan\theta}{\mathrm{C}\sec\eta}.$$

(81) $$\mathrm{D}(u_\theta) = \mathrm{D}(u_\phi) - \frac{\phi^\circ - \theta^\circ}{\mathrm{C}\cos\eta}.$$

Then with the suffix notation to denote the beginning and end of the arc $\phi - \theta$,

(82) $${}_\phi t_\theta = \mathrm{C}[\mathrm{T}(u_\phi) - \mathrm{T}(u_\theta)]$$

(83) $${}_\phi x_\theta = \mathrm{C}\cos\eta[\mathrm{S}(u_\phi) - \mathrm{S}(u_\theta)]$$

(84) $${}_\phi\left(\frac{y}{x}\right)_\theta = \tan\phi - \mathrm{C}\sec\eta\left[\mathrm{I}(u_\phi) - \frac{\Delta\mathrm{A}}{\Delta\mathrm{S}}\right],$$

Δ now denoting any finite tabular difference of the function between the initial and final (pseudo-) velocities.

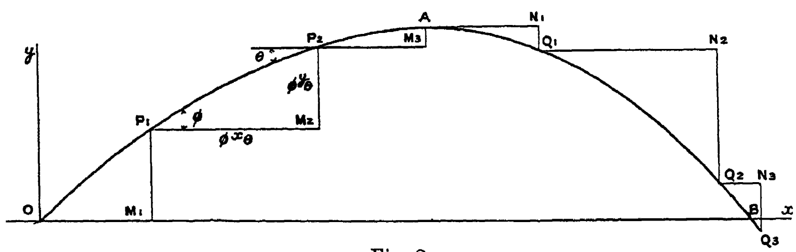

Fig. 2.

Also the velocity v_θ at the end of the arc is given by

(85) $$v_\theta = u_\theta \sec\theta \cos\eta.$$

Treating this final velocity v_θ and angle θ as the initial velocity v_ϕ and angle ϕ of the next arc, the calculation proceeds as before (Fig. 2).

In long range High Angle Fire the shot ascends to such a height that the correction for the tenuity of the air becomes important, and the curvature $\phi - \theta$ of an arc should be so chosen that ${}_\phi y_\theta$, the height ascended, should be limited to about 1000 feet, equivalent to a change of 1 inch in the barometer or 3 % in the tenuity-factor τ.

A convenient rule has been given by Captain James M. Ingalls, U.S.A., for approximating to a high angle trajectory in a single arc, which assumes that the mean density of the air may be taken as the density at two-thirds of the estimated height of the vertex; the rule is founded on the fact that in an unresisted parabolic trajectory the average height of the shot is two-thirds the height of the vertex, as illustrated in a jet of water, or in a stream of bullets from a Maxim gun.

The longest recorded range is that given in 1888 by the 9·2-inch gun to a shot weighing 380 ℔ fired with velocity 2375 f/s at elevation 40°; the range was about 12 miles, with a time for flight of about 64 seconds, shown in Fig. 2.

A calculation of this trajectory is given by Lieutenant A. H. Wolley-Dod, R.A., in the *Proceedings R.A. Institution*, 1888, employing Siacci's method and about twenty arcs; and Captain Ingalls, by assuming a mean tenuity-factor $\tau = 0{\cdot}68$, corresponding to a height of about 2 miles, on the estimate that the shot would reach a height of 3 miles, was able to obtain a very accurate result, working in a single arc over the whole trajectory (Ingalls, *Handbook of Ballistic Problems*).

Siacci's altitude-function is useful in Direct Fire, for giving immediately the angle of elevation ϕ required for a given range of R yards or X feet, between limits V and v of the velocity; also the angle of descent β.

In Direct Fire the pseudo-velocities U and u, and the real velocities V and v, are undistinguishable; so that, putting $y = 0$ in (77),

(86) $$\tan\phi = \mathrm{C}\sec\eta\left[\mathrm{I}(\mathrm{V}) - \frac{\Delta\mathrm{A}}{\Delta\mathrm{S}}\right],$$

in which $\sec\eta$ may be replaced by unity; or according to Siacci, $\sec\eta$ being replaced by $\sec^2\phi$,

(87) $$\sin 2\phi = 2\mathrm{C}\left[\mathrm{I}(\mathrm{V}) - \frac{\Delta\mathrm{A}}{\Delta\mathrm{S}}\right].$$

Also

(88) $$\tan\phi - \tan\beta = \mathrm{C}\sec\eta\,[\mathrm{I}(\mathrm{V}) - \mathrm{L}(u)]$$

in which $\sec\eta$ may be replaced by unity, so that

(89) $$\tan\beta = \mathrm{C}\left[\frac{\Delta\mathrm{A}}{\Delta\mathrm{S}} - \mathrm{I}(v)\right],$$

or, as Siacci writes it,

(90) $$\sin 2\beta = 2\mathrm{C}\left[\frac{\Delta\mathrm{A}}{\Delta\mathrm{S}} - \mathrm{I}(v)\right],$$

the two forms leading practically to the same value of β for moderate angles.

To simplify the work, so as to look out the value of $\sin 2\phi$ without the intermediate calculation of the remaining velocity v, a double-entry table has been devised by Captain Braccialini Scipione (*Problemi del Tiro*, Roma, 1883), and adapted to British units by Mr. A. G. Hadcock, late R.A., and published in the *Proc. R.A Institution*, 1898; and in *Gunnery Tables*, 1898.

In this table

(91) $$\sin 2\phi = \mathrm{C}a,$$

where a is a function tabulated for the two arguments, V the initial velocity, and $\frac{\mathrm{R}}{\mathrm{C}}$ the *reduced* range in yards.

The table is too long for insertion here, but the results for ϕ and β, as calculated for the Range Tables above, are given there for comparison.

After all care has been taken in laying and pointing, in accordance with the rules of theory and practice, absolute certainty of hitting the same spot every time is unattainable, as causes of error exist which cannot be eliminated, such as variations in the air and in the explosion of the powder charge, also in the steadiness of the shot in flight.

To obtain an estimate of the accuracy of a gun, as much actual practice as is available must be utilized, in accordance with the laws of Probability, for the calculation of the 50 per cent. zones shown in the Range Table; the article PROBABILITY must be consulted for the theory by which the percentage of hits to be expected on a given object at a known range is calculated, when the gun has been properly laid.

The Perforation of Armour.

The energy in foot-tons

(92) $$\mathrm{E} = \frac{wv^2}{2g \times 2240}$$

of a shot weighing w ℔, striking with velocity v f/s, on a target composed of iron or steel plates, or other resisting material, is used up in penetrating a certain thickness, p inches, against some unknown law of resistance of the material, as shown in the last column of the Range Table.

Empirical formulæ for the calculation of p, such as those of Fairbairn, Krupp, De Marre, Tressidder, and Gâvre, are constructed by putting

(93) $$p = k\frac{\mathrm{E}^q}{d^z}, \text{ or } \mathrm{K}\frac{w^x v^y}{d^z},$$

where d denotes the diameter of the shot, and then determining the best numbers for the indices x, y, z from experiments, plotted preferably on a logarithmic chart.

	Fair-bairn.	Krupp.	De Marre.	Tressid-der.	Gâvre.
x	$\frac{1}{2}$	$\frac{3}{4}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{5}{7}$
y	1	$\frac{3}{2}$	1	$\frac{3}{2}$	$\frac{10}{7}$
z	$\frac{1}{2}$	$\frac{5}{4}$	$\frac{3}{4}$	$\frac{1}{2}$	$\frac{15}{14}$

Taking logarithmic differentials,

$$(94) \qquad \frac{\Delta p}{p} = x\frac{\Delta w}{w} + y\frac{\Delta v}{v} - z\frac{\Delta d}{d};$$

or expressed in popular language, 1 % increase in w, v, or d, varying one at a time, is such as to cause x, y, or $-z$ % increase in p; but little reliance can be placed on these formulæ for extrapolation beyond the limits of experiments for prediction of results to be expected.

For a full discussion of these empirical formulæ, and of the numerical values of the indices x, y, z, with numerous illustrations of actual practice, consult *Armour and its Attack by Artillery*, by Captain Orde Browne.

II. Interior Ballistics.

The investigation of the relations connecting the pressure, volume, and temperature of the powder gas inside the bore of the gun, of the work realized by the expansion of the powder, of the dynamics of the movement of the shot up the bore, and of the stress set up in the material of the gun, constitutes the branch of Interior Ballistics.

A gun may be considered a simple thermodynamic machine or heat engine which does its work in a single stroke, and does not act in a series of periodic cycles as an ordinary steam or gas engine.

An indicator diagram can be drawn for a gun (Fig. 3) as for a

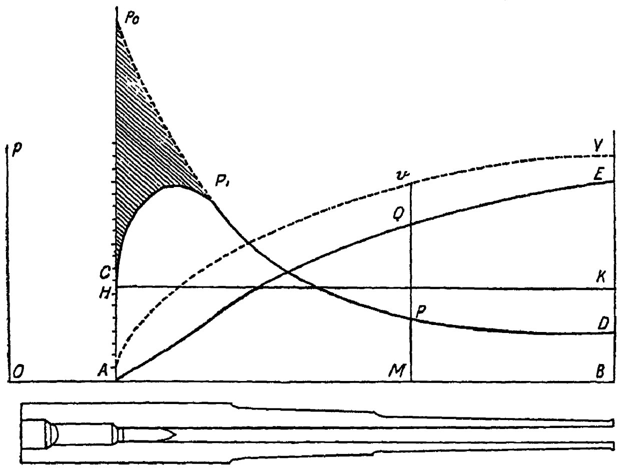

Fig. 3.

steam engine, representing graphically by a curve CPD the relation between the volume and pressure of the powder gas; and in addition the curves AQE of energy, AvV of velocity, and AtT of time can be plotted, or derived.

The velocity and energy at the muzzle B are denoted by V and E, and at any intermediate position M of the base of the shot by v and e.

After a certain discount due to friction in the bore and the energy of rotation and of recoil of the gun, the net work realized by the powder gas is represented by the area ACPM, and this is equated to the energy e of translation of the shot. The mean effective pressure (M.E.P.) in tons/inches², multiplied by $\frac{1}{4}\pi d^2$ the cross section of the bore in square inches, gives in tons the mean effective thrust X of the powder on the base of the shot; and, multiplied again by l, the length in feet of travel AM of the shot up the bore, gives the work realized in foot-tons; so that equating it to the muzzle energy

$$(1) \qquad E = \frac{wV^2}{2g \times 2240} \text{ (foot-tons)}$$

we deduce

$$(2) \qquad \text{M.E.P.} = \frac{wV^2}{2g \times 2240 \times \frac{1}{4}\pi d^2 l} \text{(tons/inches}^2\text{)}.$$

But the maximum pressure may exceed the mean in the ratio of 2 or 3 to 1, as shown in Figs. 4 and 5, representing graphically the results of Sir Andrew Noble's experiments with a 6-inch gun, capable of being lengthened to 100 calibres or 50 feet (*Proc. R.S.*, June 1894).

On the assumption of uniform pressure up the bore, practically realizable in a Zalinski pneumatic dynamite gun, the pressure curve would be a straight line parallel to AM; the energy curve AeE

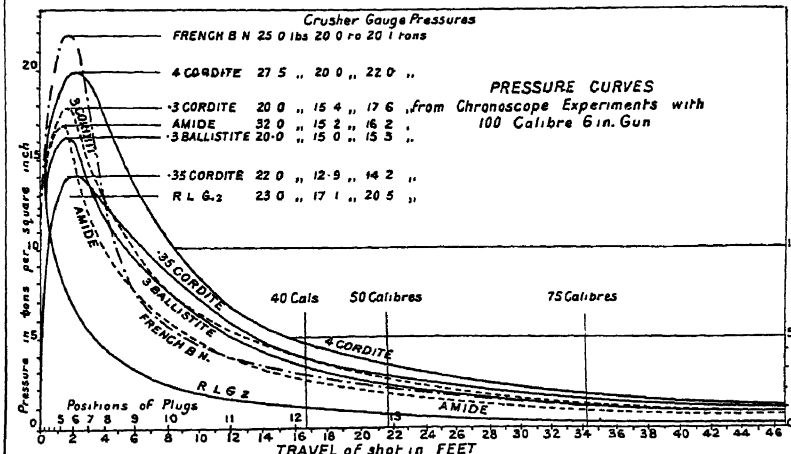

Fig. 4.

would be another straight line through A; the velocity curve AvV, of which the ordinates v are as the square roots of e, would be a parabola; and the acceleration of the shot being constant, the time curve AtT will also be a similar parabola.

If the pressure falls off uniformly, so that the pressure curve is a straight line CPD sloping downwards and cutting AM in F, then the energy curve will be a parabola curving downwards, and the velocity curve can be represented by an ellipse, or circle with centre F and radius FA; while the time curve will be a sinusoid.

But if the pressure curve is a straight line F′CP sloping upwards, cutting AM behind A in F′, the energy curve will be a parabola curving upwards, and the velocity curve a hyperbola with centre at F′.

These theorems may prove useful in preliminary calculations where the pressure curve is nearly straight; but, in the absence of any observable law, the area of the pressure curve must be read off by a planimeter, or, calculated by Simpson's rule, as an indicator diagram. To measure the pressure experimentally in the bore of a gun, the crusher gauge is used (Fig. 6); it records the maximum pressure by the compression of a copper cylinder in its interior; it may be placed in the powder chamber, or fastened in the base of the shot.

In Sir Andrew Noble's researches a number of plugs were inserted in the side of the experimental gun, reaching to the bore and carrying crusher gauges, and also chronographic appliances which registered the passage of the shot in the same manner as the electric screens in Bashforth's experiments; thence the velocity and energy of the shot was inferred, to serve as an independent control of the crusher gauge records (Figs. 4 and 5).

It was found that with modern explosives the crusher gauges

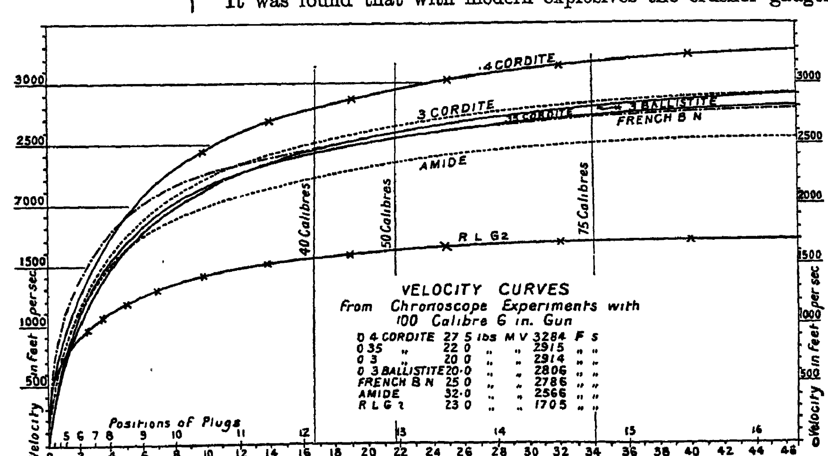

Fig. 5.

register a slightly higher pressure than the chronograph records, but a lower pressure with ordinary powder.

As a preliminary step to the determination of the pressure of

fired gunpowder in the bore of a gun, it is desirable to measure the pressure obtained by exploding charges of powder in a closed vessel, varying the weight of the charge, and thereby the density of the powder gas.

The earliest experiments of this nature are due to Benjamin Robins in 1743 and Count Rumford in 1792; and their methods have been revived by Dr Kellner, War Department chemist, who

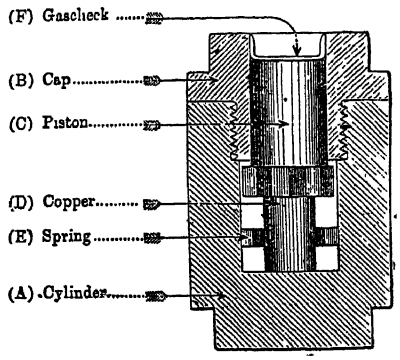

Fig. 6.

employed the steel spheres of bicycle ball bearings as safety-valves, loaded to register the pressure at which the powder gas will blow off, and thereby check the indications of the crusher gauge (*Proc. R.S.*, March 1895).

The Chevalier d'Arcy, 1760, also experimented on the pressure of powder and the velocity of the bullet in a musket barrel; this he accomplished by shortening the barrel successively, and measuring the velocity obtained by the ballistic pendulum; thus reversing Noble's procedure of gradually lengthening the gun.

But the most modern results employed with gunpowder are based on the experiments of Noble and Abel (*Phil. Trans.*, 1875–80–92–94).

Charges of powder, or other explosive, of varying weight P lb, were fired in an explosion chamber (Figs. 7, 8, and 9) of which the

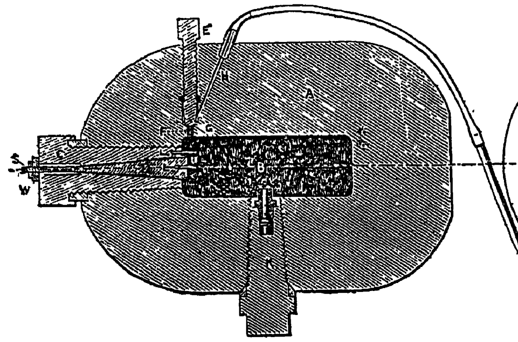

Fig. 7.

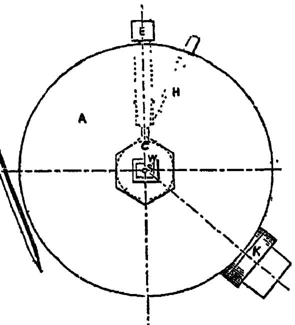

Fig. 8.

A, containing vessel of mild steel; B, charge; C, firing plug; D, conical plug; E, escape screw; F, channel of communication with charge chamber; G, mitred surface; H, passage for escape of gases when E is withdrawn; K, crusher apparatus for determining pressure; S, set screw; W, ebonite washer.

volume, C inches^3, is accurately known, and the pressure p tons/inches^2 was recorded by a crusher gauge.

The results are plotted in Figs. 10 and 11, in curves showing the relation between p and D the *gravimetric density*, which is the

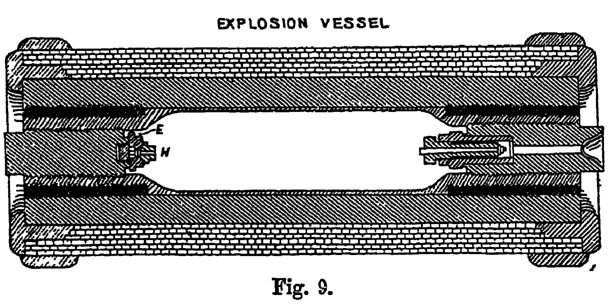

Fig. 9.

specific gravity of the P lb of powder when filling the volume C inches^3 in a state of gas; or between p and v, the reciprocal of D, which may be called the *gravimetric volume* (G. V.), being the ratio of the volume of the gas to the volume of an equal weight of water.

The results are also embodied in the following table:—

TABLE I.

G. D.	G. V.	Pressure in Tons/inches^2.

The term *gravimetric density* (G. D.) is peculiar to artillerists; it is required to distinguish between the specific gravity (S. G.) of the powder filling a given volume in a state of gas, and the specific gravity of the separate solid grains of powder.

Thus, for instance, a lump of solid lead of given S. G., when formed into a charge of lead shot composed of equal sphericles closely packed, will have a G. D. such that

(3) $$\frac{\text{G. D. of charge of lead shot}}{\text{S. G. of lump of solid lead}}=\frac{1}{6}\pi\sqrt{2}=0{\cdot}7403\,;$$

while in the case of a bundle of cylindrical sticks of cordite,

(4) $$\frac{\text{G. D. of charge of cordite}}{\text{S. G. of stick of cordite}}=\frac{1}{6}\pi\sqrt{3}=0{\cdot}9067.$$

At the standard temperature of 62° F. the volume of the gallon of 10 lb of water is 277·3 inches^3; or otherwise, 1 foot^3 or 1728 inches^3 of water at this temperature weighs 62·35 lb, and therefore 1 lb of water bulks $1728 \div 62{\cdot}35 = 27{\cdot}73$ inches^3.

Thus if a charge of P lb of powder is placed in a chamber of volume C inches^3, the

(5) $$\text{G. D.} = 27{\cdot}73\frac{\text{P}}{\text{C}}, \qquad \text{G. V.} = \frac{\text{C}}{27{\cdot}73\ \text{P}}.$$

Sometimes the factor 27·68 is employed, corresponding to a density of water of about 62·4 lb/foot^3, and a temperature 12° C., or 54° F.

With metric units, measuring P in kg., and C in litres or dm.^{3}, the G. D. = P/C, G. V. = C/P, no factor being required.

After the explosion of the powder charge P lb, it was found that

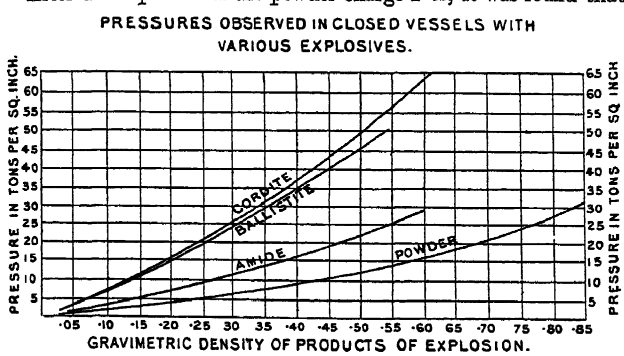

Fig. 10.

a fraction αP remained in a liquid state at S. G. unity, and therefore of volume 27·73 αP inches^3; and the remainder $(1-\alpha)$P lb was converted into a gas which filled the remaining

(6) $\quad$ C − 27·73 αP = C $(1-\alpha\text{D})$ inches^3 of the chamber;

so that the S. G. of the gas was

$$\text{(7)} \qquad \frac{27{\cdot}73\,(1-a)\mathrm{P}}{\mathrm{C}\,(1-a\mathrm{D})} = \frac{(1-a)\mathrm{D}}{1-a\mathrm{D}} = \frac{1-a}{v-a}.$$

On the assumption that the gas obeyed Boyle's law, and that the temperature of explosion was constant,

$$\text{(8)} \qquad \frac{p}{p_o} = \frac{(1-a)\mathrm{D}}{1-a\mathrm{D}} = \frac{1-a}{v-a},$$

where p_o denote the pressure when $\mathrm{D}=1$, $v=1$ and a may be called the *covolume*.

According to Noble and Abel's experiments, $p_o = 43$ tons/inches ^{2}, while the liquid residue was 57 °/ₒ of the charge, so that $a = 0{\cdot}57$; and this makes

$$\text{(9)} \qquad p = \frac{43 \times 0{\cdot}43\,\mathrm{D}}{1 - 0{\cdot}57\,\mathrm{D}} = \frac{18{\cdot}49}{v - 0{\cdot}57},$$

and the dotted line in Fig. 11 shows the theoretical curve of relation between p and v, calculated by this formula; the actual realized curve is seen to lie slightly below.

From the Table I., or by quadrature of the curve in Fig. 11, the work E in foot-tons realized by the expansion of 1 lb of the powder from one gravimetric volume to another is inferred; for if the average pressure is p tons/inches ^{2} while the gravimetric volume changes from $v - \frac{1}{2}\Delta v$ to $v + \frac{1}{2}\Delta v$, a change of volume of 27·73 Δv inches ^{3}, the work done is $27{\cdot}73\,p\,\Delta v$ inch-tons, or

$$\text{(10)} \qquad \Delta\mathrm{E} = 2{\cdot}31\,p\Delta v \text{ foot-tons};$$

and the differences $\Delta\mathrm{E}$ being calculated from the observed values of p, a summation, as in the Ballistic Tables, would give E, as tabulated in Table II.

Conversely from a table of E in terms of v, we can infer the value of p; for instance, as v changes from 4·9 to 5·1, so that $\Delta v = 0{\cdot}2$, then $\Delta\mathrm{E} = 1{\cdot}621$, making $p = 3{\cdot}5$ tons/inches ^{2}, agreeing closely with the experimental value in Table I.

TABLE II.

Work capable of being done by Exploding Gunpowder, in Expanding from Volume Unity with Unit Gravimetric Density.

On drawing off a little of the gas from the explosion vessel it was found that a gramme of powder gas (or cordite) at 0° C. and standard atmospheric pressure occupied 280 cm.^{3} (cordite 700 cm.^{3}), while the same gas compressed into 0·43 cm.^{3} at the temperature of explosion had a pressure of 43 tons/inches ^{2}, or $43 \times 2240 \div 14{\cdot}7 = 6552$ atmospheres, of 14·7 lb/inches ^{2}.

The absolute centigrade temperature T is thence inferred from the gas equation

$$\text{(11)} \qquad \mathrm{R} = \frac{pv}{\mathrm{T}} = \frac{p_o\,v_o}{273},$$

which, with $p = 6552$, $v = 0{\cdot}43$, $p_o = 1$, $v_o = 280$, makes $\mathrm{T} = 2748$, a temperature of 2475° C. or 4487° F.

If the powder charge exploded in the bore of a gun is supposed

PRESSURES IN CLOSED VESSELS OBSERVED AND CALCULATED

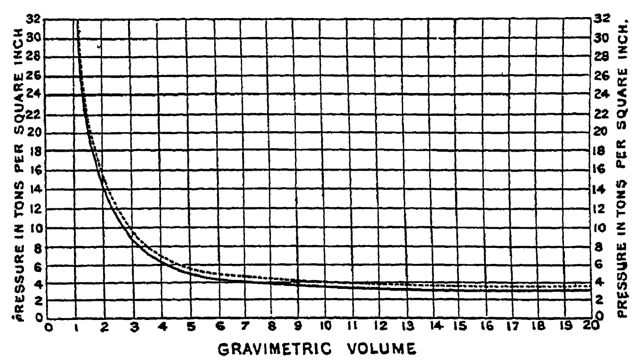

Fig. 11.

to expand according to the ordinary *adiabatic* law, then equation (8) must be changed to

$$\text{(12)} \qquad \frac{p}{p_o} = \left(\frac{1-a}{v-a}\right)^{\gamma},$$

where the index γ is the ratio $\mathrm{C}_p/\mathrm{C}_v$ of C_p the specific heat (S. H.) at constant pressure to C_v the S. H. at constant volume; and $\gamma = 1{\cdot}4$ on the average.

But, contrary to anticipation based on this adiabatic law, Noble and Abel found at an early stage of their researches that the pressure observed in a closed vessel as given theoretically at constant temperature by equation (9) did not differ greatly from the pressure in the bore of the gun itself as deduced from experiments; so that the pressure falls off much more slowly than according to the ordinary adiabatic law; and they came to the conclusion that this departure from expectation was due to the heat stored up in the liquid and solid residue.

Denoting then by β the ratio by weight of the non-gaseous to the gaseous products of the charge, and by λ the S. H. of the non-gaseous portion, supposed to be distributed in a finely divided state throughout the gas, the heat $d\mathrm{H}$ given out by the non-gaseous part during a small change of temperature $d\mathrm{T}$ is such that

$$\text{(13)} \qquad d\mathrm{H} = -\beta\lambda d\mathrm{T}.$$

The gaseous part obeys the gas-equation

$$\text{(14)} \qquad \mathrm{R} = \frac{p(v-a)}{\mathrm{T}} = \frac{p_o\,(1-a)}{\mathrm{T}_o};$$

so that

$$\text{(15)} \qquad \frac{d\mathrm{T}}{\mathrm{T}} = \frac{dp}{p} + \frac{dv}{v-a},$$

and

$$\text{(16)} \qquad \frac{d\mathrm{H}}{\mathrm{T}} = -\beta\lambda\left(\frac{dp}{p} + \frac{dv}{v-a}\right).$$

Supposing p and v to vary one at a time,

$$\text{(17)} \qquad d\mathrm{H} = \frac{\delta\mathrm{H}}{\delta p}dp + \frac{\delta\mathrm{H}}{\delta v}dv;$$

and p varying while v is constant,

$$\text{(18)} \qquad \frac{\delta\mathrm{H}}{\delta p} = \frac{\delta\mathrm{H}}{\delta\mathrm{T}}\frac{\delta\mathrm{T}}{\delta p} = \mathrm{C}_v\frac{v-a}{\mathrm{R}} = \mathrm{C}_v\frac{\mathrm{T}}{p};$$

and keeping p constant while v varies,

$$\text{(19)} \qquad \frac{\delta\mathrm{H}}{\delta v} = \frac{\delta\mathrm{H}}{\delta\mathrm{T}}\frac{\delta\mathrm{T}}{\delta v} = \mathrm{C}_p\frac{p}{\mathrm{R}} = \mathrm{C}_p\frac{\mathrm{T}}{v-a};$$

so that, in (17)

$$\text{(20)} \qquad \frac{d\mathrm{H}}{\mathrm{T}} = \mathrm{C}_v\frac{dp}{p} + \mathrm{C}_p\frac{dv}{v-a}$$

and equating the values of $d\mathrm{H}/\mathrm{T}$ in (16) and (20),

$$\text{(21)} \qquad (\mathrm{C}_v + \beta\lambda)\frac{dp}{p} + (\mathrm{C}_p + \beta\lambda)\frac{dv}{v-a} = 0.$$

Integrating

(22) $(C_v+\beta\lambda)\log p+(C_p+\beta\lambda)\log(v-\alpha)=\text{constant},$

or

(23) $$\frac{p}{p_o}=\left(\frac{1-\alpha}{v-\alpha}\right)^m$$

where

(24) $$m=\frac{C_p+\beta\lambda}{C_v+\beta\lambda}$$

reducing to the ordinary adiabatic law when $\beta=0$.

According to the experiments of Noble and Abel,

$$\alpha=0{\cdot}57,\ \beta=\frac{\alpha}{1-\alpha}=1{\cdot}3256,\ \lambda=0{\cdot}45,\ C_p=0{\cdot}2324,\ C_v=0{\cdot}1762,$$

making $m=1{\cdot}074$.

In metric units, the work done per gramme of powder in the expansion from unit G. D. or G. V. is

(25) $$\int_1^v pdv=p_o\int_1^v\left(\frac{1-\alpha}{v-\alpha}\right)^m dv$$
$$=\frac{p_o(1-\alpha)}{m-1}\left\{1-\left(\frac{1-\alpha}{v-\alpha}\right)^{m-1}\right\}$$
$$=\frac{p_o(1-\alpha)-p(v-\alpha)}{m-1}$$
$$=\frac{R}{m-1}(T_o-T).$$

In British units this must be multiplied by 2·31 to obtain E, the work in foot-tons per ℔ of powder; and with $p_o=43$ tons/inches².

(26) $$p=43\left(\frac{0{\cdot}43}{v-0{\cdot}57}\right)^{1{\cdot}074}.$$

(27) $$E=\frac{2{\cdot}31\times43\times0{\cdot}43}{0{\cdot}074}\left(1-\frac{T}{T_o}\right)$$
$$=577{\cdot}3\left(1-\frac{T}{T_o}\right),$$

so that 577·3 foot-tons is the total amount of work realizable from the infinite expansion from unit G. D. of 1 ℔ of gunpowder.

If Table II. is calculated from formula (27) the results are not very different from those obtained in the previous manner from the observed pressure in closed vessels. The table is carried up to $v=50$, and can easily be extended by means of formula (27).

In the employment of Table II. to calculate the muzzle energy and velocity to be expected from a given charge of P ℔ of powder, in expanding from the volume C inches³ of the chamber to the volume B inches³ of the bore, the initial and final gravimetric volumes (G. V.) are denoted by v_0 and v, such that

(28) $$v_o=\frac{C}{27{\cdot}73\,P},\quad v=\frac{B}{27{\cdot}73\,P};$$

these are calculated, and the difference $E(v)-E(v_o)$ of the corresponding values of E multiplied by the charge P gives the maximum realizable work in foot-tons.

In practice a *factor of effect f*, varying from 0·9 to 0·7, equivalent to a discount of 10 to 30 per cent., is required to obtain the actual net realized work stored up in the shot on leaving the muzzle.

Thus, for instance, in the 15-pounder B. L. gun, in which C=117, B=647 inches³, a charge of 4 ℔ of powder expands from $v_o=1{\cdot}054$ to $v=5{\cdot}83$, so that

(29) $E(v)-E(v_o)=97{\cdot}5113-5{\cdot}0232=92{\cdot}4881;$

and, with a factor of effect 0·7, the net muzzle energy is

(30) $0{\cdot}7\times4\times92{\cdot}4881=259$ foot-tons;

and if the shot weighs 15 ℔, this makes the muzzle velocity V = 1578 ℔.

Mr Longridge points out the necessity for some such reduction by a factor of effect f, by reason of the time occupied by the charge in combustion, during which the pressure rises to its maximum; the direct employment of Table II. assuming that the charge was consumed completely before the shot moved.

Fig. 3 shows the upper theoretical curve of pressure P_oP_1P, the area of which is tabulated in Table II.; the shaded portion represents in Longridge's theory the work to be deducted in consequence of the pressure rising gradually to a maximum p_1 along the curve CP_1, while the G. V. increases from v_o to v_1; and the actual work per ℔ of powder realized during combustion will be something less than

(31) $E_1=2{\cdot}31\,(v_1-v_o)\,p_1$ foot-tons.

The maximum pressure p_1 being supposed known, and its corresponding v_1, then during the subsequent expansion between the G.V.'s v_1 and v, the work done in foot-tons per ℔ of powder is given from Table II. by

(32) $E(v)-E(v_1).$

Suppose, for instance, that in the 15-pounder the maximum pressure is $p_1=11{\cdot}25$ tons/inches², corresponding to $v_1=2$, then

(33) $E_1=24{\cdot}6.$

(34) $E(v)-E(v_1)=48{\cdot}5,$

making the theoretical work something under 73 foot-tons per ℔; so that the factor of effect becomes about 0·9, to be accounted for by the friction in the bore and the energy of rotation.

With cordite the products of combustion are almost all gaseous, hence the absence of smoke; so that we may put $\alpha=0$, $\beta=0$ in formula (24); a good average value of m is found by experiment to be

(35) $m=1{\cdot}2;$

thence a table of the work in foot-tons per ℔ of cordite is easily calculated when the pressure p_1 tons/inches² corresponding to a given v_1 has been determined.

Thus the cordite charge of 15 oz. employed with the 15-pounder gun expands from $v_o=4{\cdot}45$ to $v=25$, and gives a muzzle velocity V = 1576 f/s to a shrapnel shell weighing 14 ℔ 1 oz.; so that the energy realized per ℔ of cordite is

(36) $$\frac{wV^2}{2g\times2240\,P}=258{\cdot}5\text{ foot-tons.}$$

If the maximum pressure $p_1=14$ tons/inches² is attained when $v_1=6$, then in accordance with Longridge's theory

(37) $E_1=2{\cdot}31\times1{\cdot}55\times14=50$ foot-tons,

and

(38) $$E(v)-E(v_1)=2{\cdot}31p_1\int_{v_1}^{v}\left(\frac{v_1}{v}\right)^m dv$$
$$=241\text{ foot-tons,}$$

making the realized work per ℔ of cordite something under 291 foot-tons; so that the factor of effect is about

(39) $f=0{\cdot}89.$

This factor f varies appreciably with the temperature, as conduction is very rapid in consequence of the small density and great heat of the cordite gas.

The discussion of the dynamical phenomena which take place in the bore during the progress of the shot is so complicated that much reliance is placed on empirical formulæ, resembling those employed for the perforation of armour plates.

Sarrau's Monomial Formula is much employed, giving the muzzle velocity

(40) $$V=HP^x w^y d^p D^q\left(\frac{B}{C}\right)^r,$$

where the symbols have their previous meaning, and H is a factor depending on the quality and structure of the powder; and this formula can, as before, be interpreted in popular language as equivalent to saying that 1 % change in P, w, d, D, B/C causes x, y, p, q, r % change in V.

In the old rule of Robins and Hutton, that the muzzle energy is proportional to the charge, ignoring the effect of calibre, density of loading, and number of expansions in the bore, we put

$$x=\tfrac{1}{2},\ y=-\tfrac{1}{2},\ p,\ q,\ r=0.$$

For quick powder, entirely consumed in the bore, Sarrau takes

(41) $x=\frac{3}{8},\ y=-\frac{1}{2},\ p=\frac{1}{4},\ q=\frac{1}{4},\ r=\frac{1}{8}.$

For slow powder, some of which is blown out of the muzzle unconsumed, he takes—

(42) $x=\frac{3}{8},\ y=-\frac{7}{16},\ p=\frac{1}{8},\ q=\frac{1}{4},\ r=\frac{3}{16}.$

These indices are readily determined by plotting a few experimental results on a logarithmic chart.

Gunpowder. See PROPELLANTS.

Guntur, a town of British India, in the Kistna district of Madras, a station on the branch of the Southern Mahratta Railway from Bellary to Bezwara. Population (1881), 19,646; (1891), 23,267; municipal income (1897–98), Rs.46,470. It is a centre for trade in grain and cotton, with five cotton-presses. The American Lutheran Mission supports a college. There are two high schools, two printing-presses, and two literary associations.

Gurdaspur, a town (with a population in 1891 of 5189) and district of British India, in the Lahore division of the Punjab. The District comprises an area of 1889 square miles. Population (1881), 823,965; (1891), 943,922, being 500 persons per square mile; (1901), 940,595, showing a slight decrease, compared with an increase of 15 per cent. in the previous decade. The land revenue and rates were Rs.16,56,082, the incidence of assessment being R.1–4–9 per acre; the number of police was 536; the cultivated area in 1896–97 was 812,760 acres, of which 210,375 were irrigated, including 37,101 from government canals; the number of schools in 1896–97 was 296, with 9968 pupils, the proportion of boys at school to the male population of school-going age being 12·2 per cent.; the registered death-rate in 1897 was 24·97 per 1000. There are seven printing-presses, issuing one English and one vernacular newspaper. A branch of the North-Western Railway runs for 48 miles through the district. There are 80 miles of navigable river, and 26 miles of metalled roads. The largest town is Batala. The sanitarium of Dalhousie, though situated in the native state of Chamba, is attached to Gurdaspur.

Gurgaon, a district of British India, in the Delhi division of the Punjab, comprising an area of 1984 square miles. Population (1881), 641,848; (1891), 668,929, being 337 persons per square mile; (1901), 745,877, showing an increase of 11 per cent. The land revenue and rates were Rs.13,71,138, the incidence of assessment being R.1–1–11 per acre; the number of police was 520; the cultivated area in 1896–97 was 817,975 acres, of which 217,421 were irrigated, including 92,085 from government canals; the number of schools in 1896–97 was 149, with 4834 pupils, the proportion of boys at school to the male population of school-going age being 9 per cent.; the registered death-rate in 1897 was 37·36 per 1000. There are two printing-presses, four factories for cleaning and pressing cotton, seventeen small indigo factories, and two saltpetre refineries. The largest town is Rewari. There are altogether 62 miles of railway, 30 miles of navigable river, and 79 miles of metalled roads. The district is also traversed by the Agra canal.

Guriev, or Guriev Gorodok, formerly Yaitskiy Gorodok, a district town of Russia, government of Uralsk, on the right bank of the Ural, 11 miles above its mouth, in a malarial neighbourhood. It has considerable fisheries, and is in steamer communication with Astrakhan; trade is carried on with the Kirghiz, especially at the fairs. Population, 9320.

Gurney, Edmund (1847–1888), English psychologist, was born at Hersham, near Walton-on-Thames, 23rd March 1847. He was educated at Blackheath and at Trinity College, Cambridge, where he took a high place in the classical tripos, and obtained a fellowship. His work for the schools was done, says his friend Mr Myers, "in the intervals of his practice on the piano." Dissatisfied with his own executive skill as a musician, he wrote *The Power of Sound* (1880), an essay on the philosophy of music. He then studied medicine with no intention of practising, devoting himself to physics, chemistry, and physiology. In 1880 he passed the second M.B. Cambridge examination in the science of the healing profession. These studies, and his great logical powers and patience in the investigation of evidence, he devoted to that outlying field of psychology which is called "Psychical Research." He asked whether, as universal tradition declares, there is an unexplored region of human faculty transcending the normal limitations of sensible knowledge. That there is such a region it was part of the system of Hegel to declare, and the subject had been metaphysically treated by Hartmann, Schopenhauer, Du Prel, Hamilton, and others, as the philosophy of the Unconscious, or Subconscious. But Gurney's purpose was to approach the subject by observation and experiment, especially in the hypnotic field, whereas vague and ill-attested anecdotes had hitherto been the staple of the evidence of metaphysicians. The tendency of his mind was to investigate whatever facts may give a colour of truth to the ancient belief in the persistence of the conscious human personality after the death of the body. Like Joseph Glanvil's, the natural bent of Gurney's mind was sceptical. Both thought the current and traditional reports of supernormal occurrences suggestive and worth investigating by the ordinary methods of scientific observation, and inquisition into evidence at first hand. But the method of Gurney was, of course, much more strict than that of the author of *Sadducismus Triumphatus,* and it included hypnotic and other experiments unknown to Glanvil. Mr Gurney began at what he later saw was the wrong end by studying, with Mr Myers, the "séances" of professed spiritualistic "mediums" (1874–78). Little but detection of imposture came of this, but an impression was left that the subject ought not to be abandoned. In 1882 the Society for Psychical Research was founded. (See Psychical Research.) Paid mediums were discarded, at least for the time, and experiments were made in "thought-transference" and hypnotism. Personal evidence as to uninduced hallucinations was also collected. The first results are embodied in the volumes of *Phantasms of the Living,* a vast collection (Podmore, Myers, and Gurney), and in Mr Gurney's remarkable essay, *Hallucinations.* The chief consequence was to furnish evidence for the process called "telepathy," involving the provisional hypothesis that one human mind can affect another through no recognized channel of sense. The fact was supposed to be established by the experiments chronicled in the *Proceedings of the Society for Psychical Research,* and it was argued that similar experiences occurred spontaneously, as, for example, in the many recorded instances of "deathbed wraiths" among civilized and savage races. (Tylor, *Primitive Culture,* i., chapter xi., especially pages 449–450, 1873. Lang, *Making of Religion,* pages 120–124, 1898.) The dying man is supposed to convey the hallucination of his presence as one living person experimentally conveys his thought to another, by "thought-transference." Mr Gurney's hypnotic experiments, marked by great exactness, patience, and ingenuity, were undertaken in 1885–88. Their tendency was, in Mr Myers's words, "to prove—so far as any one operator's experience in this protean subject can be held to prove anything—that there *is* sometimes, in the induction of hypnotic phenomena, some agency at work which is neither ordinary nervous stimulation (monotonous or sudden) nor suggestion conveyed by any ordinary channel to the subject's mind." These results, if accepted, of course corroborate the idea of telepathy. (See Gurney, "Hypnotism and Telepathy," *Proceedings S.P.R.,* vol. iv.) Experiments by MM. Gibert, Janet, Richet, Héricourt, and others are cited as tending in the same direction. Other experiments dealt with "the relation of the memory in the hypnotic state to the memory in another hypnotic state, and of both to the normal, or waking memory." All this work has been more appreciated by Continental than by British *savants.* The result of Mr Gurney's labours, cut short by his early and regretted death, has been to raise and strengthen the presumption that there exists an unexplored region of human faculty which ought not to be neglected by science as if the belief in it were a mere survival of savage superstition. Rather, it appears to have furnished

the experiences which, misinterpreted, are expressed in traditional beliefs. That Mr Gurney was credulous, and easily to be imposed upon, those who knew him, and knew his penetrating humour, cannot admit; nor is the theory likely to be maintained by those whom bias does not prevent from studying with care his writings. In controversy "he delighted in replying with easy courtesy to attacks envenomed with that *odium plus quam theologicum* which the very allusion to a ghost or the human soul seems in some philosophers to inspire." In discussion of themes unpopular and obscure Mr Gurney displayed the highest tact, patience, good temper, humour, and acuteness. There never was a more disinterested student. In addition to his work on music and his psychological writings, he was the author of *Tertium Quid* (1887), a collection of essays, on the whole a protest against one-sided ideas and methods of discussion. He died at Brighton on 23rd June 1888, from the effects of an overdose of narcotic medicine. (A. L.)

Gütersloh, a town of the province of Westphalia, Prussia, 11 miles S.W. from Bielefeld by the railway to Dortmund. It is the seat of silk and cotton industries, and has a trade in Westphalian hams and sausages. Printing, brewing, and distilling are also carried on. It is famous for its rye-bread (*pumpernickel*). Population (1900), 7100.

Guthrie, capital of Logan county, Oklahoma, U.S.A., and the capital of the territory, on the river Cottonwood and the Atchison, Topeka, and Santa Fé Railway, at an altitude of 939 feet. The city was founded in 1889, and one year later had a population of 2788. In 1900 the population (including what in 1890 was Guthrie, East Guthrie, and West Guthrie towns) had increased to 10,006, of whom 301 were foreign-born and 3036 negroes.

Gwalior, a native state of India, in the Central India Agency, with a total area of about 29,000 miles, and a population in 1881 of 2,951,014, and in 1891 of 3,366,496, giving an average density of 116 persons per square mile. In 1901 the population of the Gwalior Agency, which is not coextensive with the state of Gwalior, was returned as 2,149,958, showing an increase of 3 per cent. The gross revenue is about Rs.1,50,00,000 (say, one million sterling). In 1896–97 the land revenue yielded Rs.67,15,700, and Rs.38,80,323 was expended on the army. There was an accumulated balance of about Rs.10,00,00,000, of which more than half was invested. The number of schools was 261 (including two colleges and three high schools), attended by 13,772 pupils, of whom 1346 were learning English. The present Maharaja, Madhava Rao Sindhia, G.C.S.I., was born in 1877, and succeeded in 1886. During his minority the state was administered for eight years by a council of regency. He was entrusted with ruling powers in 1894, and has in all respects continued the reforming policy of the council, while paying personal attention to every department. A survey has been introduced for land revenue; large sums have been devoted to railways; active measures have been adopted for the suppression of *dakaiti*, or gang robbery—the scourge of Central India; and roads, bridges, hospitals, and schools have been built. The survey, under an English officer, shows that about one-third of the total area is cultivated, and that one-thirteenth of the cultivated area is irrigated. The assessment ranges from Rs.20 to Rs.50 per plough. The railways undertaken by the state are—(1) from Bina on the Indian Midland to Goona (74 miles); (2) an extension of this line to Bara (74 miles), opened in 1899; (3) from Bhopal to Ujain (114 miles); (4) two light railways, from Gwalior to Sipri and Gwalior to Bhind (total length, 127 miles), which were opened by the Viceroy in November 1899. On the same occasion the Viceroy opened the Victoria College, founded to commemorate the Diamond Jubilee; and the Memorial Hospital, built in memory of the Maharaja's father. The northern portion of the state suffered from famine in 1897, and the southern portion in 1900. British currency has been introduced instead of Chandori rupees, which were much depreciated. Two regiments of imperial service cavalry are maintained, and also a transport corps of ponies and carts, which did good service in the Chitral and Tirah campaigns. In 1900 the Maharaja equipped at his own cost a hospital ship for the China war, and himself accompanied it. The CITY OF GWALIOR is 76 miles by rail south of Agra. The population in 1881 was 88,066, in 1891 it was 104,083. It has a college with 400 students, a high school, a girls' school with 115 pupils, a service school to train officials, a law class, hospitals for men and for women, a museum, a palace, lighted by electricity, a paper-mill, and a printing-press, issuing a state gazette.

GYMNOSPERMS.

THE Gymnosperms form with the Angiosperms the great division of seed-bearing plants or Phanerogams. As the name implies, one characteristic is the absence of an ovary or closed chamber containing the ovules. These naked-seeded plants are of special interest on account of their great antiquity, which far exceeds that of other Flowering Plants, and as comprising different types which carry us back to the Palæozoic era and to the forests of the Coal Period. The best known and by far the largest division of the Gymnosperms is that of the cone-bearing trees (pines, firs, cedars, larches, &c.), which play a prominent part in the vegetation of the present day, especially in the higher latitudes of the northern hemisphere; certain members of this class are of considerable antiquity, but the Conifers as a whole are still vigorous, and show no signs of decadence. The division known as the Cycadales is represented by a few living genera of limited geographical range, and by a large number of extinct types which in the Mesozoic era (see PALÆOBOTANY, MESOZOIC) played a conspicuous part in the vegetation of the world. Palæobotanical evidence has rendered it probable that the Cycads sprang from a common ancestry with Ferns. Among the Cycadales we find surviving types which, in their present isolation, their close resemblance to fossil forms, and in certain morphological features, constitute links with the past that not only connect the present with former periods in the earth's history, but serve as sign-posts pointing the way back along one of the many lines which evolution has followed. The Cordaitales (see PALÆOBOTANY, PALÆOZOIC) are represented by extinct forms only, which occupied a prominent position in the Palæozoic period; these plants exhibit certain features in common with the living Araucarias, and others which invite a comparison with the Maidenhair tree (*Ginkgo biloba*), the solitary survivor of another class of Gymnosperms, the Ginkgoales (see PALÆOBOTANY, MESOZOIC). The Gnetales are a class apart, including three living genera, of which we know next to nothing as regards their past history or line of descent.

Gymnospermæ.—Trees or shrubs; leaves vary considerably in size and form. Flowers unisexual, except in a few cases (Gnetales) without a perianth. Monœcious or diœcious. Ovules naked, rarely without carpellary leaves, usually borne on carpophylls, which assume various forms. The single megaspore enclosed in the nucellus is filled with tissue (prothallus) before fertilization, and contains two or more archegonia, consisting usually of a large egg-cell and a small neck, rarely of an egg-cell only and no neck (*Gnetum* and *Welwitschia*). Microspore spherical or oval, with or without a bladder-like extension of the exine, containing a prothallus of two or more cells, one of which produces two non-motile or motile male cells. Cotyledons two or several. Secondary xylem and phloem produced by a single cambium, or by successive cambial zones; no true vessels (except in the Gnetales) in the wood, and no companion-cells in the phloem.

I. Cycadales.—A. *Cycadaceæ*, B. *Bennettitaceæ* (extinct).
II. Cordaitales (extinct).
III. Ginkgoales.—A single recent genus, *Ginkgo*.
IV. Coniferales.—A. *Taxaceæ*, B. *Pinaceæ*.
V. Gnetales.—A. *Ephedroideæ*, B. *Gnetoideæ*, C. *Welwitschioideæ*.

Cycadales.—A. *Cycadaceæ*.—Stems tuberous or columnar, not infrequently branched, fronds pinnate, bi-pinnate in the Australian genus *Bowenia*. Diœcious; flowers in the form of cones, except the female flowers of *Cycas*, which consist of a rosette of leaf-like carpels at the apex of the stem. Seeds albuminous, with one integument; the single embryo, usually bearing two partially fused cotyledons, is attached to a long tangled suspensor. Stems and roots increase in diameter by secondary thickening, the secondary wood being produced by one cambium or developed from successive cambium-rings.

The Cycads constitute a homogeneous group of a few living members confined to tropical and sub-tropical regions. As a fairly typical and well known example of the Cycadaceæ, a species of the genus *Cycas* (e.g., *C. circinalis*, *C. revoluta*, &c.) is briefly described. The stout columnar stem (see *Ency. Brit.*, vol. iv., Plate 15) may reach a height of 20 metres, and a diameter of half a metre; it remains either unbranched or divides near the summit into several short and thick branches, each branch terminating in a crown of long pinnate leaves. The surface of the stem is covered with rhomboidal areas, which represent the persistent bases of foliage- and scale-leaves. In some species of *Cycas* there is a well-defined alternation of transverse zones on the stem, consisting of larger areas representing foliage-leaf bases, and similar but smaller areas formed by the bases of scale-leaves (*F* and *S*. Fig. 1). The scale-leaves clothing the terminal bud are linear-lanceolate in form, and of a brown or yellow colour; they are pushed aside as the stem-axis elongates, and become shrivelled, finally falling off, leaving projecting bases which are eventually cut off at a still lower level. Similarly, the dead fronds fall off, leaving a ragged petiole, which is afterwards separated from the stem by an absciss-layer a short distance above the base. In some species of *Cycas* the leaf-bases do not persist as a permanent covering to the stem, but the surface is covered with a wrinkled bark, as in *Cycas Siamensis*, which has a stem of unusual form (Fig. 2). Small tuberous shoots, comparable on a large scale with the bulbils of *Lycopodium Selago*, are occasionally produced in the axils of some of the persistent leaf-bases; these are characteristic of sickly plants, and serve as a means of vegetative reproduction. In the genus *Cycas* the female flower is peculiar among Cycads in consisting of a terminal crown of separate leaf-like carpels several inches in length; the apical portion of each carpellary leaf may be broadly triangular in form, and deeply dissected on the margins into narrow woolly appendages like rudimentary pinnæ. From the lower part of a carpel are produced several laterally placed ovules, which become bright red or orange on ripening; the bright fleshy seeds, which in some species are as large as a goose's egg, and the tawny spreading carpels produce a pleasing combination of colour in the midst of the long dark green fronds, which curve gracefully upwards and outwards from the summit of the columnar stem. In *Cycas* the stem-apex, after producing a cluster of carpellary leaves, continues to elongate, and produces more bud-scales, which are afterwards pushed aside as a fresh crown of fronds is developed. The young leaves of *Cycas* consist of a straight rachis bearing numerous linear pinnæ, traversed by a single midrib; the pinnæ are circinately coiled like the leaf of a fern (Fig. 3). The male flower of *Cycas* conforms to the type of structure characteristic of the *Cycads*, and consists of a long cone of numerous sporophylls bearing many oval pollen-sacs on their lower faces. The type described serves as a convenient representative of its class. There are eight other living genera, which may be classified as follows:—

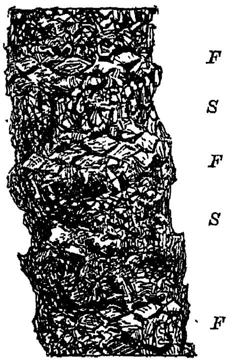

Fig. 1.—Stem of *Cycas*. *F*, foliage-leaf bases; *S*, scale-leaf bases.

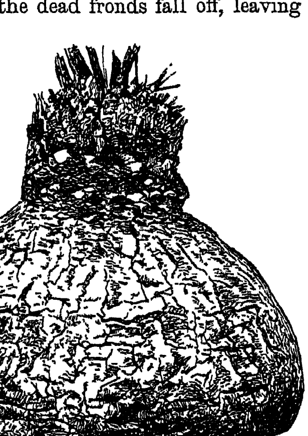

Fig. 2.—*Cycas Siamensis*.

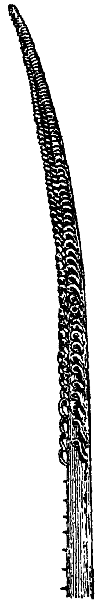

Fig. 3.—*Cycas*: young frond.

Classification.—A. *Cycadeæ*.—Characterized by (*a*) the alternation of scale- and foliage-leaves (Fig. 1) on the branched or unbranched stem; (*b*) the growth of the main stem through the female flower; (*c*) the presence of a prominent single vein in the linear pinnæ; (*d*) the structure of the female flower, which is peculiar in not having the form of a cone, but consists of numerous independent carpels, each of which bears two or more lateral ovules. Represented by a single genus, *Cycas*. (Tropical Asia, Australia, &c.)

B. *Zamieæ*.—The stem does not grow through the female flower; both male and female flowers are in the form of cones. (a) *Stangerieæ*.—Characterized by the fern-like venation of the pinnæ, which have a prominent midrib, giving off at a wide angle simple or forked and occasionally anastomosing lateral veins. A single genus, *Stangeria*, confined to South Africa. (b) *Euzamieæ*.—The pinnæ are traversed by several parallel veins. *Bowenia*, an Australian Cycad, is peculiar in having bi-pinnate fronds (Fig. 5). The various genera are distinguished from one another by the shape and manner of attachment of the pinnæ, the form of the carpellary scales, and to some extent by anatomical characters. *Encephalartos* (South Africa).—Large cones; the carpellary scales terminate in a peltate distal expansion. *Macrozamia* (Australia).—Similar to *Encephalartos*, except in the presence of a spinous projection from the swollen distal end of the carpels. *Zamia* (South America, Florida, &c.).—Stem short and often divided into several columnar branches. Each carpel terminates in a peltate head. *Ceratozamia* (Mexico).—Similar in habit to *Macrozamia*, but distinguished by the presence of two horn-like spinous processes on the apex of the carpels. *Microcycas* (Cuba).—Like *Zamia*, except that the ends of the stamens are flat, while the apices of the carpels are peltate. *Dioon* (Mexico).—Characterized by the woolly scale-leaves and carpels; the latter terminate in a thick laminar expansion of triangular form, bearing two placental cushions, on which the ovules are situated. *Bowenia* (Australia).—Bi-pinnate fronds; stem short and tuberous (Fig. 5).

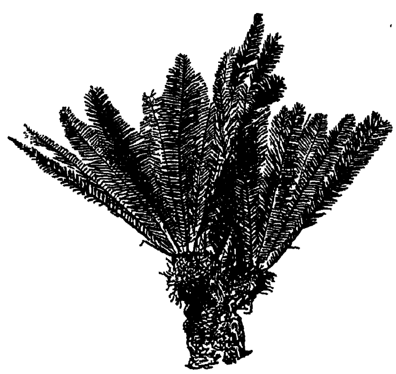

Fig. 4.—*Dioon edule*. (From a photograph of a plant in the Peradeniya Gardens, Ceylon, by R. H. Yapp.)

Stem and Leaf.

The stems of Cycads are often described as unbranched; it is true that in comparison with Conifers, in which the numerous branches, springing from the main stem, give a characteristic form to the tree, the tuberous or columnar stem of the Cycadaceæ constitutes a striking distinguishing feature. Branching, however, occurs not infrequently; in *Cycas* the tall stem often produces several candelabra-like arms; in *Zamia* the main axis may break up near the base into several cylindrical branches; in species of *Dioon* (Fig. 4), *Encephalartos*, &c., lateral branches are occasionally produced. The thick armour of petiole-bases enveloping the stem is a characteristic Cycadean feature; in *Cycas* the alternation of scale-leaves and fronds is more clearly shown than in other Cycads; in *Encephalartos*, *Dioon*, &c., the persistent scale-leaf bases are almost equal in size to those of

the foliage-leaves, and there is no regular alternation of zones such as characterizes some species of *Cycas*. Another type of stem is illustrated by *Stangeria* and *Zamia*, also by a few forms of *Cycas* (Fig. 2), in which the fronds fall off completely, leaving a comparatively smooth stem. The *Cycas* type of frond, except as regards the presence of a midrib in each pinna, characterizes the Cycads generally, except *Bowenia* and *Stangeria*. In the monotypic genus *Bowenia* the large fronds, borne singly on the short and thick stem, are bi-pinnate (Fig. 5); the segments, which are

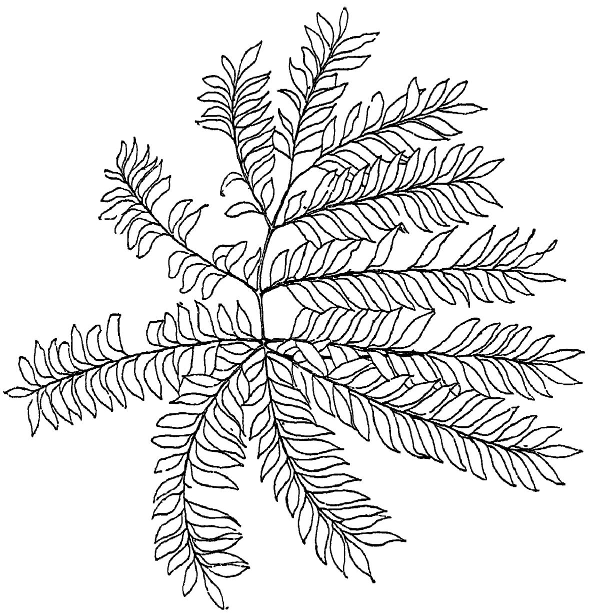

FIG. 5.—*Bowenia spectabilis*: frond.

broadly ovate or rhomboidal, have several forked spreading veins, and resemble the large pinnules of some species of *Adiantum*. In *Stangeria*, also a genus represented by one species (*S. paradoxa* of South Africa), the long and comparatively broad pinnæ, with an entire or irregularly incised margin, are very fern-like, a circumstance which led Kunze to describe the plant in 1835 as a species of the fern *Lomaria*. In rare cases the pinnæ of Cycads are lobed or branched: in *Dioon spinulosum* (Central America) the margin of the segments bears numerous spinous processes; in some species of *Encephalartos*, e.g., *E. horridus*, the lamina is deeply lobed; and in a species of the Australian genus *Macrozamia*, *M. heteromera*, the narrow pinnæ are dichotomously branched almost to the base (Fig. 6), and resemble the frond of some species of the fern *Schizæa*, or the fossil genus *Baiera* (Ginkgoales). In *Ceratozamia* the broad petiole-base is characterized by the presence of two lateral spinous processes, suggesting stipular appendages, comparable, on a reduced scale, with the large stipules of the Marattiaceæ among Ferns. The vernation varies in different genera; in *Cycas* the rachis is straight and the pinnæ circinately coiled (Fig. 3); in *Encephalartos*, *Dioon*, &c., both rachis and segments are straight; in *Zamia* the rachis is bent or slightly coiled, bearing straight pinnæ. The young leaves arise on the stem-apex as conical protuberances with winged borders, on which the pinnæ appear as rounded humps, usually in basipetal order; the scale-leaves in their young condition resemble fronds, but the lamina remains undeveloped. A feature of interest in connexion with the phylogeny of Cycads is the presence of long hairs clothing the scale-leaves, and forming a cap on the summit of the stem apex or attached to the bases of petioles; on some fossil cycadean plants these outgrowths have the form of scales, and are identical in structure with the ramenta (paleæ) of the majority of ferns.

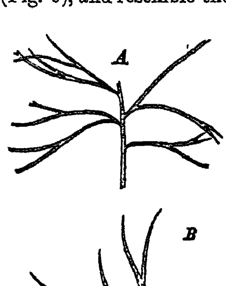

FIG. 6.—*Macrozamia heteromera*. *A*, part of frond; *B*, single pinna.

Flower.

The male flowers of Cycads are constructed on a uniform plan, and in all cases consist of an axis bearing crowded, spirally disposed sporophylls. These are often wedge-shaped and angular; in some cases they consist of a short, thick stalk, terminating in a peltate expansion, or prolonged upwards in the form of a triangular lamina. (See *Ency. Brit.*, vol. iv., Plate 15.) The sporangia (pollen-sacs), which occur on the under-side of the stamens, are often arranged in more or less definite groups or sori, interspersed with hairs (paraphyses); dehiscence takes place along a line marked out by the occurrence of smaller and thinner-walled cells bounded by larger and thicker-walled elements, which form a fairly prominent cap-like "annulus" near the apex of the sporangium, not unlike the annulus characteristic of the Schizæaceæ among Ferns. The sporangial wall, consisting of several layers of cells, encloses a cavity containing numerous oval spores (pollen-grains). In structure a cycadean sporangium recalls those of certain ferns (Marattiaceæ, Osmundaceæ, and Schizæaceæ), but in the development of the spores there are certain peculiarities not met with among the Vascular Cryptogams. With the exception of *Cycas*, the female flowers are also in the form of cones, bearing numerous carpellary scales. In *Cycas revoluta* and *C. circinalis* each leaf-like carpel may produce several laterally attached ovules, but in *C. Normanbyana* the carpel is shorter and the ovules are reduced to two; this latter type brings us nearer to the carpels of *Dioon*, in which the flower has the form of a cone, and the distal end of the carpels is longer and more leaf-like than in the other genera of the Zamieæ, which are characterized by shorter carpels with thick peltate heads bearing two ovules on the morphologically lower surface. The cones of Cycads attain in some cases (e.g., *Encephalartos*) a considerable size, reaching a length of more than a foot.

Micro-spores and mega-spores.

The pollen-grains when mature consist of three cells, two small and one large cell; the latter grows into the pollen-tube, as in the Coniferales, and from one of the small cells two large ciliated spermatozoids are eventually produced. One of the most important botanical discoveries made during the latter part of the 19th century was that by Ikeno, a Japanese botanist, who was the first to demonstrate the existence of motile male-cells in the genus *Cycas*. Similar spermatozoids have been observed also in some species of *Zamia* by Webber, an American botanist, and Lang has found traces of ciliated cells in *Stangeria*. Before following the growth of the pollen-grain after pollination, we will briefly describe the structure of a cycadean ovule. An ovule consists of a conical nucellus surrounded by a single integument. At an early stage of development a large cell makes its appearance in the central region of the nucellus; this increases in size and eventually forms three cells; the lowest of these grows vigorously and constitutes the megaspore (embryo-sac), which ultimately absorbs the greater part of the nucellus. The megaspore-nucleus divides repeatedly, and cells are produced from the peripheral region inwards, which eventually fill the spore-cavity with a homogeneous tissue (prothallus); some of the superficial cells at the micropylar end of the megaspore increase in size and divide by a tangential wall into two, an upper cell which gives rise to the short two-celled neck of the archegonia, and a

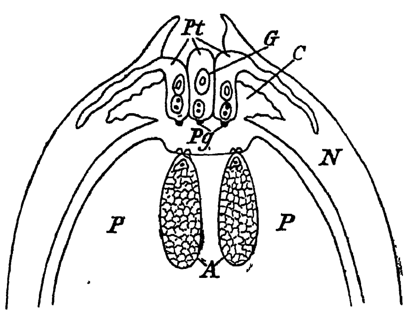

FIG. 7.—*Zamia*: part of ovule in longitudinal section. *P*, prothallus; *A*, archegonia; *N*, nucellus; *C*, pollen-chamber; *Pt*, pollen-tube; *Pg*, pollen-grain; *G*, generative cell (second cell of pollen-tube). (After Webber.)

lower cell which develops into a large egg-cell. Each megaspore may contain 2 to 6 archegonia. During the growth of the ovum nourishment is supplied from the contents of the cells immediately surrounding the egg-cell, as in the development of the ovum of *Pinus* and other Conifers. Meanwhile the tissue in the apical region of the nucellus has been undergoing disorganization, which results in the formation of a large space or pollen-chamber (Fig. 7, *C*), situated immediately above the megaspore. The pollen-grains find their way between the carpophylls, which at the time of pollination are slightly apart owing to the elongation of the internodes of the flower-axis, and pass into the pollen-chamber; the large cell of the pollen-grain grows out into a tube (*Pt*), which penetrates the nucellar tissue and often branches repeatedly; the pollen-grain itself, with the prothallus-cells, projects freely into the pollen-chamber (Fig. 7). The nucleus of the outermost (second) small cell (Fig. 7, *G*) divides, and one of the daughter-nuclei passes out of the cell, and may enter the lowest (first) small cell. The outermost cell, by the division of the remaining nucleus, produces two large spermatozoids (Fig. 8, *a*, *a*). In the course of this division two bodies make their appearance in the cytoplasm, and behave as centrosomes during the karyokinesis; they gradually become thread-like and coil themselves round each daughter nucleus. (See CYTOLOGY, VEGETABLE.) This thread gives rise to a spiral ciliated band lying in a depression on the body of each sper-

matozoid, which ends posteriorly in a short tail formed of cytoplasm; the spermatozoids eventually escape from the pollen-tube, and are able to perform ciliary movements in the watery liquid which occurs between the thin papery remnant of nucellar tissue and the archegonial necks. Before fertilization a neck-canal cell is formed by the division of the ovum-nucleus. After the body of a spermatozoid has coalesced with the egg-nucleus the latter divides repeatedly and forms a mass of tissue which grows more vigorously in the lower part of the fertilized ovum, and extends upwards towards the apex of the ovum as a peripheral layer of parenchyma surrounding a central space. By further growth this tissue gives rise to a proembryo, which consists, at the micropylar end, of a sac; the tissue at the chalazal end grows into a long and tangled suspensor, terminating in a mass of cells, which is eventually differentiated into a radicle, plumule, and two cotyledons. In the ripe seed the integument assumes the form of a fleshy envelope, succeeded internally by a hard woody shell, internal to which is a thin papery membrane—the apical portion of the nucellus—which is easily dissected out as a conical cap covering the apex of the endosperm. A central depression occurs in the apex of the endosperm, in which may be seen the remains of additional archegonia. The first leaves borne on the seedling axis are often scale-like, and these are followed by two or more larger laminæ, which foreshadow the pinnæ of the adult frond.

The anatomical structure of the vegetative organs of recent Cycads is of special interest as affording important evidence of relationship with extinct types, and with other groups of recent plants.

Anatomy.

Brongniart, who was the first to investigate in detail the anatomy of a cycadean stem, recognized an agreement, as regards the secondary wood, with Dicotyledons and Gymnosperms, rather than with Monocotyledons. He drew attention also to certain structural similarities between *Cycas* and *Ginkgo*. The main anatomical features of a cycad stem may be summarized as follows: The centre is occupied by a large parenchymatous pith traversed by numerous secretory canals, and in some genera by cauline vascular bundles (e.g., *Encephalartos* and *Macrozamia*). In addition to these cauline strands (confined to the stem and not connected with the leaves), collateral bundles are often met with in the pith, which form the vascular supply of terminal flowers borne at intervals on the apex of the stem. These latter bundles may be seen in sections of old stems to pursue a more or less horizontal course, passing outwards through the main woody cylinder. This lateral course is due to the more vigorous growth of the lateral vegetative branch formed near the base of each flower, which is a terminal structure, and, except in the female flower of *Cycas*, puts a limit to the apical growth of the stem. The vigorous lateral branch therefore continues the line of the main axis. The pith is encircled by a cylinder of secondary wood, consisting of single or multiple radial rows of tracheids separated by broad medullary rays composed of large parenchymatous cells; the tracheids bear numerous bordered pits on the radial walls. The large medullary rays give to the wood a characteristic parenchymatous or lax appearance, which is in marked contrast to the more compact wood of a conifer. The protoxylem-elements are situated at the extreme inner edge of the secondary wood, and may occur as small groups of narrow, spirally-pitted elements scattered among the parenchyma which abuts on the main mass of wood. Short and reticulately-pitted tracheal cells, similar to tracheids, often occur in the circummedullary region of cycadean stems. In an old stem of *Cycas*, *Encephalartos*, or *Macrozamia* the secondary wood consists of several rather unevenly concentric zones, while in some other genera it forms a continuous mass as in Conifers and normal Dicotyledons. These concentric rings of secondary xylem and phloem (Fig. 9) afford a characteristic cycadean feature. After the cambium has been active for some time producing secondary xylem and phloem, the latter consisting of sieve-tubes, phloem-parenchyma, and frequently thick-walled fibres, a second cambium is developed in the pericycle; this produces a second vascular zone, which is in turn followed by a third cambium, and so on, until several hollow cylinders are developed. It has been recently shown that several cambium-zones may remain in a state of activity, so that the formation of a new cambium does not necessarily mark a cessation of growth in the more internal meristematic rings. It occasionally happens that groups of xylem and phloem are developed internally to some of the vascular rings; these are characterized by an inverse orientation of the tissues, the xylem being centrifugal and the phloem centripetal in its development. The broad cortical region, which contains many secretory canals, is traversed by numerous vascular bundles (Fig. 9, *c*), some of which pursue a more or less vertical course, and by frequent anastomoses with one another form a loose reticulum of vascular strands; others are leaf-traces on their way from the stele of the stem to the leaves. Most of these cortical bundles are collateral in structure, but in some the xylem and phloem are concentrically arranged; the secondary origin of these bundles from procambium-strands was described by Mettenius in his classical paper of 1860. During the increase in thickness of a cycadean stem successive layers of cork-tissue are formed by phellogens in the persistent bases of leaves (Fig. 9, *pd*), which increase in size to adapt themselves to the growth of the vascular zones. The leaf-traces of Cycads are remarkable both on account of their course and their anatomy. In a transverse section of a stem (Fig. 9) one sees some vascular bundles following a horizontal or slightly oblique course in the cortex, stretching for a longer or shorter distance in a direction concentric with the woody cylinder. From each leaf-base two main bundles spread right and left through the cortex of the stem (Fig. 9, *lt*), and as they curve gradually towards the vascular ring they present the appearance of two rather flat ogee curves, usually spoken of as the leaf-trace girdles (Fig. 9, *lt*). The distal ends of these girdles give off several branches, which traverse the petiole and rachis as numerous collateral bundles. A leaf-trace, as it passes through the cortex, has a collateral structure, the protoxylem being situated at the inner edge of the xylem; when it reaches the leaf-base the position of the spiral tracheids is gradually altered, and the endarch arrangement (protoxylem internal) gives place to a mesarch structure (protoxylem more or less central and not on the edge of the xylem strand). In a bundle examined in the basal portion of a leaf the bulk of the xylem is found to be centrifugal in position, but internally to the protoxylem there is a group of centripetal tracheids; higher up in the petiole the xylem is mainly centripetal, the centrifugal wood being represented by a small arc of tracheids external to the protoxylem and separated from it by a few parenchymatous elements. Finally, in the pinnæ of the frond the centrifugal xylem may disappear, the protoxylem being now exarch in position and abutting on the phloem. Similarly in the sporophylls of some Cycads the bundles are endarch near the base and mesarch near the distal end of the stamen or carpel. The vascular system of cycadean seedlings presents some features worthy of note; centripetal xylem occurs in the cotyledonary bundles associated with transfusion-tracheids. The bundles from the cotyledons pursue a direct course to the stele of the main axis, and do not assume the girdle-form characteristic of the adult plant. This is of interest from the point of view of the comparison of recent Cycads with some fossil cycadean plants (Bennettiteæ), in which the leaf-traces follow a much simpler course than in modern Cycads. The mesarch structure of the leaf-bundles is met with in a less pronounced form in the flower peduncles of some Cycads. This fact is of importance as showing that this type of vascular structure, which characterized the stems of many Palæozoic genera, has not entirely disappeared from the stems of modern Cycads; but the mesarch bundle is now confined to the leaves and peduncles.

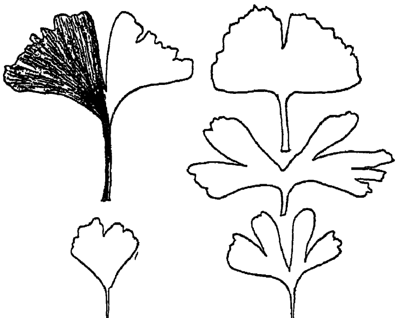

FIG. 10.—*Ginkgo biloba*: leaves.

Roots.

The roots of some Cycads resemble the stems in producing several cambium-rings; they possess 2 to 8 protoxylem-groups, and are characterized by a broad pericyclic zone. A common phenomenon in Cycads is the production of roots which grow upwards (apogeotropic), and appear as coralline branched structures above the level of the ground; some of the cortical cells of these roots are hypertrophied, and contain numerous filaments of blue-green

Algæ (Nostocaceæ), which live as endoparasites in the cell-cavities.

GINKGOALES.—This class-designation has been recently proposed to give emphasis to the isolated position of the genus *Ginkgo* (*Salisburia*) among the Gymnosperms. *Ginkgo biloba*, the Maiden-hair tree, has usually been placed by botanists in the Taxeæ in the neighbourhood of the Yew (*Taxus*), but the proposal by Eichler in 1852 to institute a special family, the Salisburieæ, indicated a recognition of the existence of special characteristics which distinguish the genus from other members of the Coniferæ. The discovery by the Japanese botanist Hirase of the development of ciliated spermatozoids in the pollen-tube of *Ginkgo*, in place of the non-motile male cells of typical Conifers, served as a cogent argument in favour of separating the genus from the Coniferales and placing it in a class of its own. In 1712 Kaempfer published a drawing of a Japanese tree, which he described under the name *Ginkgo;* this term was adopted in 1771 by Linnæus, who spoke of Kaempfer's plant as *Ginkgo biloba.* In 1797 Smith proposed to use the name *Salisburia adiantifolia* in preference to the "uncouth" genus *Ginkgo* and the "incorrect" specific term *biloba.* Both names are still in common use. On account of the resemblance of the leaves to those of some species of *Adiantum*, the appellation Maiden-hair tree has long been given to *Ginkgo biloba. Ginkgo* is of special interest on account of its isolated position among existing plants, its restricted geographical distribution, and its great antiquity (see PALÆOBOTANY, MESOZOIC). This solitary survivor of an ancient stock is almost extinct in a wild state, but a few large trees still flourish in parts of China and possibly in Japan; it is common as a sacred tree in the gardens of temples in the Far East, and often cultivated in North America and Europe. *Ginkgo biloba*, which may reach a height of over 30 metres, forms a tree of pyramidal shape with a smooth grey bark. The leaves (Figs. 10 and 11) have a long, slender petiole terminating in a fan-shaped lamina, which may be entire, divided by a median incision into two wedge-shaped lobes or subdivided into several narrow segments. The venation is like that of many ferns, e.g., *Adiantum;* the lowest vein in each half of the lamina follows a course parallel to the edge, and gives off numerous branches, which fork repeatedly as they spread in a palmate manner towards the leaf margin. The foliage-leaves occur either scattered on long shoots of unlimited growth, or at the apex of short shoots (spurs), which may eventually elongate into long shoots.

FIG. 11.—*Ginkgo adiantoides.* Fossil (Eocene) leaf from the island of Mull.

Flowers. The flowers are diœcious. The male flowers (Fig. 12), borne in the axil of scale-leaves, consist of a stalked central axis bearing loosely disposed stamens; each stamen consists of a slender filament terminating in a small apical scale, which bears usually two, but not infrequently three or four pollen-sacs (Fig. 12, *C*). The axis of the flower is a shoot bearing leaves in the form of stamens. A mature pollen-grain contains a prothallus of 3 to 5 cells (Fig. 13, *Pg*); the exine extends over two-thirds of the circumference, leaving a thin portion of the wall, which on collapsing produces a longitudinal groove similar to the median depression on the pollen-grain of a cycad. The ordinary type of female flower has the form of a long, naked peduncle bearing a single ovule on either side of the apex (Fig. 12), the base of each being enclosed by a small, collar-like rim, the nature of which has been variously interpreted. A young ovule consists of a conical nucellus surrounded by a single integument terminating as a two-lipped micropyle. A large pollen-chamber occupies the apex of the nucellus; immediately below this, two or more archegonia (Fig. 13, *a*) are developed in the upper region of the megaspore, each consisting of a large egg-cell surmounted by two neck-cells and a canal-cell which is cut off shortly before fertilization. After the entrance of the pollen-grain the pollen-chamber becomes roofed over by a blunt protuberance of nucellar tissue. The megaspore (embryo-sac) continues to grow after pollination until the greater part of the nucellus is gradually destroyed; it also gives rise to a vertical outgrowth, which projects from the apex of the megaspore as a short, thick column (Fig. 13, *e*) supporting the remains of the nucellar tissue which forms the roof of the pollen-chamber (Fig. 13, *c*). Surrounding the pitted wall of the ovum there is a definite layer of large cells, no doubt representing a tapetum, which, as in Cycads and Conifers, plays an important part in nourishing the growing egg-cell. The endosperm detached from a large *Ginkgo* ovule after fertilization bears a close resemblance to that of a cycad; the apex is occupied by a depression, on the floor of which two small holes mark the position of the archegonia, and the outgrowth from the megaspore apex projects from the centre as a short peg. After pollination the pollen-tube grows into the nucellar tissue, as in Cycads, and the pollen-grain itself (Fig. 13, *Pg*) hangs down into the pollen-chamber; two large spirally ciliated spermatozoids are produced, their manner of development agreeing very closely with that of the corresponding cells in *Cycas* and *Zamia.* After fertilization the ovum-nucleus divides and cell-formation proceeds rapidly, especially in the lower part of the ovum, in which the cotyledon and axis of the embryo are differentiated; the long, tangled suspensor of the cycadean embryo is not found in *Ginkgo.* It is often stated that fertilization occurs after the ovules have fallen, but it has been demonstrated by Hirase that this occurs while the ovules are still attached to the tree. The ripe seed, which grows as large as a rather small plum, is enclosed by a thick, fleshy envelope covering a hard woody shell with two or rarely three longitudinal keels. A papery remnant of nucellus lines the inner face of the woody shell, and, as in cycadean seeds, the apical portion is readily separated as a cap covering the summit of the endosperm.

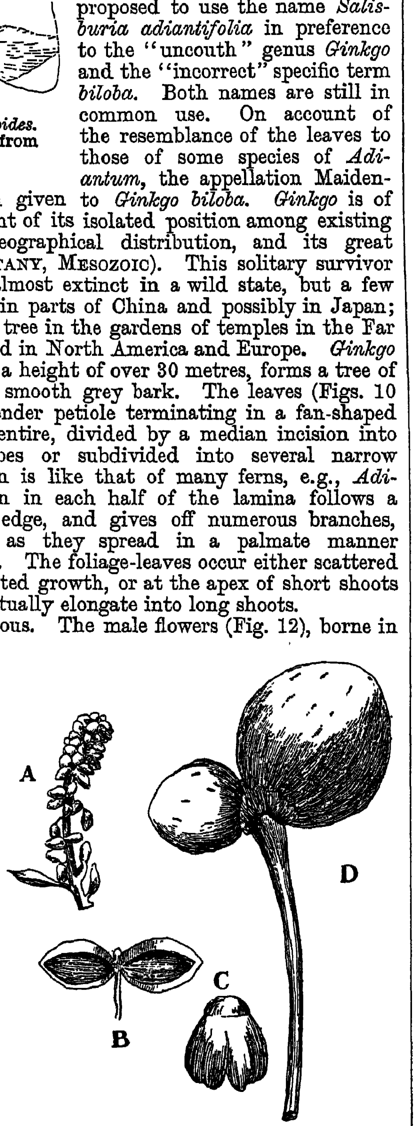

FIG. 12.—*Ginkgo biloba. A*, male flower; *B, C*, single stamens; *D*, female flower.

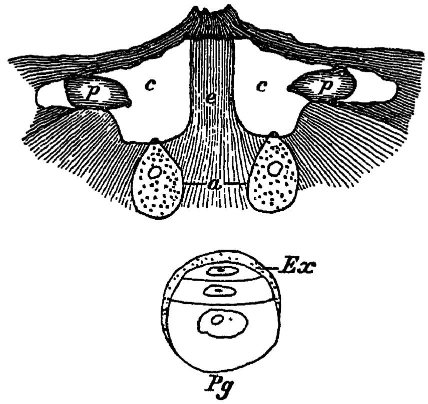

FIG. 13.—*Ginkgo:* apex of ovule, and pollen-grain. *p*, pollen-tube (proximal end); *c*, pollen-chamber; *e*, upward prolongation of megaspore; *a*, archegonia; *Pg*, pollen-grain; *Ex*, exine. (After Hirase.)

The morphology of the female flowers has been variously interpreted by botanists; the peduncle bearing the ovules has been described as homologous with the petiole of a foliage-leaf and as a shoot-structure, the collar-like envelope at the base of the ovules being referred to as a second integument or arillus, or as the representative of a carpel. The evidence afforded by normal and abnormal flowers appears to be in favour of the following interpretation: The peduncle is a shoot bearing two or more carpels. Each ovule is enclosed at the base by an envelope or collar homologous with the lamina of a leaf; the fleshy and hard coats of the nucellus constitute a single integument. The stalk of an ovule, considerably reduced in normal flowers and much larger in some abnormal flowers, is homologous with a leaf-stalk, with which it agrees in the structure and number of vascular bundles. The facts on which this description is based are derived partly from anatomical evidence, and in part from an account given by a Japanese botanist, Fujii, of several abnormal female flowers; in some cases the collar at the base of an ovule, often described as an arillus, is found to pass gradually into the lamina of a leaf bearing marginal ovules (Fig. 14, *B*). The occurrence of more than two ovules on one peduncle is by no means rare; a particularly striking example is described by Fujii, in which an unusually thick peduncle

FIG. 14.—*Ginkgo:* abnormal female flowers. *A*, peduncle; *b*, scaly bud; *B*, leaf bearing marginal ovule. (After Fujii.)

bearing several stalked ovules terminates in a scaly bud (Fig. 14, *A*, *b*). The frequent occurrence of more than two pollen-sacs and the equally common occurrence of additional ovules have been regarded by some authors as evidence in favour of the view that ancestral types normally possessed a greater number of these organs than are usually found in the recent species. This view receives support from fossil evidence.

Anatomy. Close to the apex of a shoot the vascular bundles of a leaf make their appearance as double strands, and the leaf-traces in the upper part of a shoot have the form of distinct bundles, which in the older part of the shoot form a continuous ring. Each double leaf-trace passes through four internodes before becoming a part of the stele; the double nature of the trace is a characteristic feature. Secretory sacs occur abundantly in the leaf-lamina, where they appear as short lines between the veins; they are abundant also in the cortex and pith of the shoot, in the fleshy integument of the ovule, and elsewhere. The secondary wood of the shoot and root conforms in the main to the Coniferous type; in the short shoots the greater breadth of the medullary rays in the more internal part of the xylem recalls the cycadean type. The secondary phloem contains numerous thick-walled fibres, parenchymatous cells, and large sieve-tubes with plates on the radial walls; swollen parenchymatous cells containing crystals are commonly met with in the cortex, pith, and medullary-ray tissues. The wood consists of tracheids, with circular bordered pits on their radial walls, and in the late summer wood pits are unusually abundant on the tangential walls. A point of anatomical interest is the occurrence in the vascular bundles of the cotyledons, scale-leaves, and elsewhere of a few centripetally developed tracheids, which give to the xylem-strands a mesarch structure such as characterizes the foliar bundles of Cycads. The root is diarch in structure, but additional protoxylem-strands may be present at the base of the main root; the pericycle consists of several layers of cells.

This is not the place to discuss in detail the past history of *Ginkgo* (see PALÆOBOTANY, MESOZOIC). Among Palæozoic genera there are some which bear a close resemblance to the recent type in the form of the leaves, and petrified Palæozoic seeds, almost identical with those of the Maidenhair tree, have been described from French and English localities.

Geological history. During the Triassic and Jurassic periods the genus *Baiera*—no doubt a representative of the Ginkgoales—was widely spread throughout Europe and in other regions; *Ginkgo* itself occurs abundantly in Mesozoic and Tertiary rocks, and was a common plant in the Arctic regions during the Jurassic and Lower Cretaceous periods. Some unusually perfect *Ginkgo* leaves have been found in the Eocene leaf-beds between the lava-flows exposed in the cliffs of Mull (Fig. 11). From an evolutionary point of view, it is of interest to note the occurrence of filicinean and cycadean characters in the Maidenhair tree. The leaves at once invite a comparison with Ferns; the numerous long hairs which form a delicate woolly covering on young leaves recall the hairs of certain ferns, but agree more closely with the long filamentous hairs of recent Cycads. The spermatozoids constitute the most striking link with both Cycads and Ferns. The structure of the seed, the presence of two neck-cells in the archegonia, the late development of the embryo, the partially-fused cotyledons and certain anatomical characters, are features common to *Ginkgo* and the Cycads. The Maidenhair tree is one of the most interesting survivals from the past; it represents a type which, in the Palæozoic era, may have been merged into the extinct class Cordaitales. Through the succeeding ages the Ginkgoales were represented by numerous forms, which gradually became more restricted in their distribution and fewer in number during the Cretaceous and Tertiary periods, terminating at the present day in one solitary survivor.

CONIFERALES.—Trees and shrubs characterized by a copious branching of the stem and frequently by a regular pyramidal form. Leaves simple, small, linear or short and scale-like, usually persisting for more than one year. Flowers monœcious or diœcious, unisexual, without a perianth, often in the form of cones, but never terminal on the main stem.

The plants usually included in the Coniferæ constitute a less homogeneous class than the Cycadaceæ. Some authors use the term Coniferæ in a restricted sense as including those genera which have the female flowers in the form of cones, the other genera, characterized by flowers of a different type, being placed in the Taxaceæ, and often spoken of as Taxads. In order to avoid confusion in the use of the term Coniferæ, we may adopt as a class-designation the name Coniferales, including both the Coniferæ—using the term in a restricted sense—and the Taxaceæ.

External features. The most striking characteristic of the majority of the Coniferales is the regular manner of the monopodial branching and the pyramidal shape. *Araucaria imbricata*, the Monkey-puzzle tree, *A. excelsa*, the Norfolk Island Pine, many Pines and Firs, Cedars, and other genera illustrate the pyramidal form. The mammoth Redwood tree of California, *Sequoia* (*Wellingtonia*) *gigantea*, which represents the tallest Gymnosperm, and among the Angiosperms is exceeded only by the Eucalyptus trees of Australia, is a good example of the regular tapering main stem and narrow pyramidal form. The Cypresses afford instances of tall and narrow trees similar in habit to Lombardy Poplars. The common Cypress (*Cupressus sempervirens*), as found wild in the mountains of Crete and Cyprus, is characterized by long and spreading branches, which give it a Cedar-like habit. A pendulous or weeping habit is assumed by some Conifers; e.g., *Picea excelsa* var. *virgata* represents a form in which the main branches attain a considerable horizontal extension, and trail themselves like snakes along the ground. Certain species of *Pinus*, the Yews (*Taxus*), and some other genera grow as bushes, which in place of a main mast-like stem possess several repeatedly-branched leading shoots. The unfavourable conditions in Arctic regions have produced a dwarf form, in which the main shoots grow close to the ground. Artificially induced dwarfed plants of *Pinus*, *Cupressus*, *Sciadopitys* (Umbrella Pine), and other genera are commonly cultivated by the Japanese. The dying off of older branches and the vigorous growth of shoots nearer the apex of the stem produce a form of tree illustrated by the Stone Pine of the Mediterranean region (*Pinus Pinea*), which Turner has rendered familiar in his "Childe Harold's Pilgrimage" and other pictures of Italian scenery. Conifers are not infrequently seen in which a lateral branch has bent sharply upwards to take the place of the injured main trunk. An upward tendency of all the main lateral branches, known as fastigiation, is common in some species, producing well-marked varieties, e.g., *Cephalotaxus pedunculata* var. *fastigiata*; this fastigiate habit may arise as a sport on a tree with spreading branches. Another departure from the normal is that in which the juvenile or seedling form of shoot persists in the adult tree; the numerous Coniferous plants known as species of *Retinospora* are examples of this. The name *Retinospora*, therefore, does not stand for a true genus, but denotes persistent young forms of *Juniperus*, *Thuja*, *Cupressus*, &c., in which the small scaly leaves of ordinary species are replaced by the slender, needle-like leaves, which stand out more or less at right angles from the branches. The flat branchlets of *Cupressus*, *Thuja* (Arbor Vitæ), *Thujopsis dolabrata* (Japanese Arbor Vitæ) are characteristic of certain types of Conifers; in some cases the horizontal extension of the branches induces a dorsiventral structure. A characteristic feature of the genus *Agathis* (*Dammara*), the Kauri Pine of New Zealand, is the deciduous habit of the branches; these become detached from the main trunk by a well-defined absciss-surface, which appears as a depressed circular scar on the stem.

With a few exceptions Conifers are evergreen, and retain the leaves for several years (10 years in *Araucaria imbricata*, 8 to 10 in *Picea excelsa*, 5 in *Taxus baccata*; in *Pinus* the needles usually fall in October of their third year).

Leaves. The Larch (*Larix*) sheds its leaves in the autumn, in the Chinese Larch (*Pseudolarix Kaempferi*) the leaves turn a bright yellow colour before falling. In the swamp Cypress (*Taxodium distichum*) the tree assumes a rich brown colour in the autumn, and sheds its leaves together with the branchlets which bear them; deciduous branches occur also in some other species, e.g., *Sequoia sempervirens* (Redwood), *Thuja occidentalis*, &c. The leaves of Conifers are characterized by their small size; *e.g.*, the needle-form represented by *Pinus*, *Cedrus*, *Larix*, &c., the linear flat or angular leaves, appressed to the branches, of *Thuja*, *Cupressus*, *Libocedrus*, &c. The flat and comparatively broad leaves of *Araucaria imbricata*, *A. Bidwillii*, and some species of the southern genus *Podocarpus* are traversed by several parallel veins, as are also the still larger leaves of *Agathis*, which may reach a length of several inches. In addition to the foliage-leaves several genera also possess scale-leaves of various kinds, represented by bud-scales in *Pinus*, *Picea*, &c., which frequently persist for a time at the base of a young shoot which has pushed its way through the yielding cap of protecting scales, while in some Conifers the bud-scales adhere together, and after being torn near the base are carried up by the growing axis as a thin brown cap. The Cypresses, Araucarias, and some other genera have no true bud-scales; in some species, e.g., *Araucaria Bidwillii*, the occurrence of small foliage-leaves, which have functioned as bud-scales, at intervals on the shoots affords a measure of seasonal growth. The occurrence of long and short shoots is a characteristic feature of many Conifers. In *Pinus* the needles occur in pairs, or in clusters of 3 or 5 at the apex of a small and inconspicuous short shoot of limited growth (spur), which is enclosed at its base by a few scale-leaves, and borne on a branch of unlimited growth in the axil of a scale-leaf. In the Californian *Pinus monophylla* each spur bears usually one needle, but two are not uncommon; it would seem that rudiments of two needles are always produced, but, as a rule, only one develops into a needle. In *Sciadopitys* similar spurs occur, each bearing a single needle, which in its grooved surface and in the possession of a double vascular bundle bears traces of an origin from two needle-leaves. A peculiarity of these leaves is the inverse orientation of the vascular tissue; each of the two veins has its phloem next the upper and the xylem towards the lower surface of the leaf; this

unusual position of the xylem and phloem may be explained by regarding the needle of *Sciadopitys* as being composed of a pair of leaves borne on a short axillary shoot and fused by their margins (Fig. 15, A). Long and short shoots occur also in *Cedrus* and *Larix*, but in these genera the spurs are longer and stouter, and are not shed with the leaves; this kind of short shoot, by accelerated apical growth, often passes into the condition of a long shoot, on which the leaves are scattered and separated by comparatively long internodes instead of being crowded into tufts such as are borne on the ends of the spurs. In the genus *Phyllocladus* (New Zealand, &c.) there are no green foliage-leaves, but in their place flattened branches (phylloclades) borne in the axils of small scale-leaves. The cotyledons are often two in number, but sometimes (e.g., *Pinus*) as many as fifteen; these leaves are usually succeeded by foliage-leaves in the form of delicate spreading needles, and these primordial leaves are followed, sooner or later, by the adult type of leaf, except in Retinosporas, which retain the juvenile foliage. In addition to the first foliage-leaves and the adult type of leaf, there are often produced leaves which are intermediate both in shape and structure between the seedling and adult foliage. Dimorphism or heterophylly is fairly common. One of the best known examples is the Chinese Juniper (*J. Chinensis*), in which branches with spinous leaves, longer and more spreading than the ordinary adult leaf, are often found associated with the normal type of branch. In some cases, e.g., *Sequoia sempervirens*, the fertile branches bear leaves which are less spreading than those on the vegetative shoots. Certain species of the southern hemisphere genus *Dacrydium* afford particularly striking instances of heterophylly, e.g., *D. Kirkii* of New Zealand, in which some branches bear small and appressed leaves, while in others the leaves are much longer and more spreading. A well-known fossil Conifer from Triassic strata—*Voltzia heterophylla*—also illustrates a marked dissimilarity in the leaves of the same shoot. The variation in leaf-form and the tendency of leaves to arrange themselves in various ways on different branches of the same plant are features which it is important to bear in mind in the identification of fossil Conifers. In this connexion we may note the striking resemblance between some of the New Zealand Alpine Veronicas, e.g., *Veronica Hectori*, *V. Cupressoides*, &c. (also *Polycladus cupressinus*, a Composite), and some of the Cypresses and other Conifers with small appressed leaves. The long linear leaves of some species of *Podocarpus*, in which the lamina is traversed by a single vein, recall the pinnæ of *Cycas*; the branches of some Dacrydiums and other forms closely resemble those of Lycopods; these superficial resemblances, both between different genera of Conifers and between Conifers and other plants, coupled with the usual occurrence of fossil coniferous twigs without cones attached to them, render the determination of extinct types a very unsatisfactory and frequently an impossible task.

Flowers.

A typical male flower consists of a central axis bearing numerous spirally-arranged sporophylls (stamens), each of which consists of a slender stalk (filament) terminating distally in a more or less prominent knob or triangular scale, and bearing two or more pollen-sacs (microsporangia) on its lower surface. The pollen-grains of some genera (e.g., *Pinus*) are furnished with bladder-like extensions of the outer wall, which serve as aids to wind-dispersal. The stamens of *Araucaria* and *Agathis* are peculiar in bearing several long and narrow free pollen-sacs; these may be compared with the sporangiophores of the Horsetails (*Equisetum*); in *Taxus* (Yew) the filament is attached to the centre of a large circular distal expansion, which bears several pollen-sacs on its under surface. In the Conifers proper the female reproductive organs have the form of cones, which may be styled flowers or inflorescences according to different interpretations of their morphology. In the Taxaceæ the flowers have a simpler structure. The female flowers of the Abietineæ may be taken as representing a common type. A pine cone reaches maturity in two years; a single year suffices for the full development in *Larix* and several other genera. The axis of the cone bears numerous spirally disposed flat scales (cone-scales), each of which, if examined in a young cone, is found to be double, and to consist of a lower and an upper portion. The latter is a thin flat scale bearing a median ridge or keel (e.g., *Abies*), on each side of which is situated an inverted ovule, consisting of a nucellus surrounded by a single integument. As the cone grows in size and becomes woody the lower half of the cone-scale, which we may call the carpellary scale, may remain small, and is so far outgrown by the upper half (seminiferous scale) that it is hardly recognizable in the mature cone. In many species of *Abies* (e.g., *Abies pectinata*, &c.) the ripe cone differs from those of *Pinus*, *Picea*, and *Cedrus* in the large size of the carpellary scales, which project as conspicuous thin appendages beyond the distal margins of the broader and more woody seminiferous scales; the long carpellary scale is a prominent feature also in the cone of the Weymouth Pine (*Pseudotsuga Douglasii*). The female flowers (cones) vary considerably in size; the largest are the more or less spherical cones of *Araucaria*—a single cone of *A. imbricata* may produce as many as 300 seeds, one seed to each fertile cone-scale—and the long pendent cones, 1 to 2 feet in length, of the Sugar Pine of California (*Pinus Lambertiana*) and other species. Smaller cones, less than an inch long, occur in the Larch, *Athrotaxis* (Tasmania), *Fitzroya* (Patagonia and Tasmania), &c. In the Taxodieæ and Araucarieæ the cones are similar in appearance to those of the Abietineæ, but they differ in the fact that the scales appear to be single, even in the young condition; each cone-scale in a genus of the Taxodiinæ (*Sequoia*, &c.) bears several seeds, while in the Araucariinæ (*Araucaria* and *Agathis*) each scale has one seed. The Cupressineæ have cones composed of a few scales arranged in alternate whorls; each scale bears two or more seeds, and shows no external sign of being composed of two distinct portions. In the Junipers the scales become fleshy as the seeds ripen, and the individual scales fuse together in the form of a berry. The female flowers of the Taxaceæ assume another form; in *Microcachrys* (Tasmania) the reproductive structures are spirally disposed, and form small globular cones made up of red fleshy scales, to each of which is attached a single ovule enclosed by an integument and partially invested by an arillus; in *Dacrydium* the carpellary leaves are very similar to the foliage leaves—each bears one ovule with two integuments, the outer of which constitutes an arillus. Finally in the Yew, as a type of the family Taxeæ, the ovules occur singly at the apex of a lateral branch, enclosed when ripe by a conspicuous red or yellow fleshy arillus, which serves as an attraction to animals, and thus aids in the dispersal of the seeds.

It is important to draw attention to some structural features exhibited by certain cone-scales, in which there is no external sign indicative of the presence of a carpellary and a seminiferous scale. In *Araucaria Cookii* and some allied species each scale has a small pointed projection from its upper face near the distal end; the scales of *Cunninghamia* (China) are characterized by a somewhat ragged membranous projection extending across the upper face between the seeds and the distal end of the scale; in the scales of *Athrotaxis* (Tasmania) a prominent rounded ridge occupies a corresponding position. These projections and ridges may be homologous with the seminiferous scale of the Pines, Firs, Cedars, &c. The simplest interpretation of the cone of the Abietineæ is that which regards it as a flower consisting of an axis bearing several open carpels, which in the adult cone may be very small or large and prominent, the scale bearing the ovules being regarded as a placental outgrowth from the flat and open carpel. In *Araucaria* the cone-scale is regarded as consisting of a flat carpel, of which the placenta has not grown out into the scale-like structure. The seminiferous scale of *Pinus*, &c., is also spoken of sometimes as a ligular outgrowth from the carpellary leaf. Robert Brown was the first to give a clear description of the morphology of the Abietineous cone in which carpels bear naked ovules; he recognized gymnospermy as an important distinguishing feature in Conifers as well as in Cycads. Another view is to regard the cone as an inflorescence, each carpellary scale being a bract bearing in its axil a shoot the axis of which has not been developed; the seminiferous scale is believed to represent either a single leaf or a fused pair of leaves belonging to the partially suppressed axillary shoot. In 1869 van Tieghem laid stress on anatomical evidence as a key to the morphology of the cone-scales; he drew attention to the fact that the collateral vascular bundles of the seminiferous scale are inversely orientated as compared with those of the carpellary scale; in the latter the xylem of each bundle is next the upper surface, while in the

Morphology of female flower.

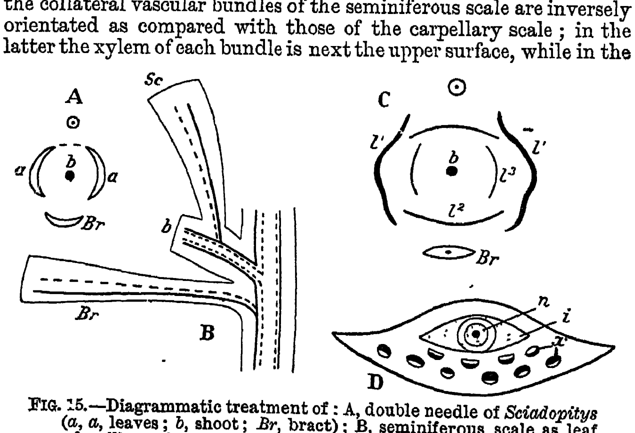

FIG. 15.—Diagrammatic treatment of: A, double needle of *Sciadopitys* (a, a, leaves; b, shoot; *Br*, bract); B, seminiferous scale as leaf of axillary shoot (b, shoot; *Sc*, seminiferous scale; *Br*, bract); C, seminiferous scale as fused pair of leaves (l^1, l^2, l^3, first, second, and third leaves; b, shoot; *Br*, bract); D, cone-scale of *Araucaria* (n, nucellus; i, integument; x, xylem) (C and D after Worsdell).

seminiferous scale the phloem occupies that position. The conclusion drawn from this was that the seminiferous scale (Fig. 15, B, *Sc*) is the first and only leaf of an axillary shoot (b) borne on that side of the shoot, the axis of which is suppressed, opposite the subtending bract (Fig. 15, A, B, C, *Br*). Another view is to apply to the seminiferous scale an explanation similar to that suggested by von Mohl

in the case of the double needle of *Sciadopitys*, and to consider the seed-bearing scale as being made up of a pair of leaves (Fig. 15, A, *a*, *a*) of an axillary shoot (*b*) fused into one by their posterior margins (Fig. 15, A). The latter view receives support from abnormal cones in which carpellary scales subtend axillary shoots, of which the first two leaves (Fig. 15, C, l^1, l^1) are often harder and browner than the others; forms have been described transitional between axillary shoots, in which the leaves are separate, and others in which two of the leaves are more or less completely fused. In a young cone the seminiferous scale appears as a hump of tissue at the base or in the axil of the carpellary scale, but Celakovsky, a strong supporter of the axillary bud theory, attaches little or no importance to this kind of evidence, regarding the present manner of development as being merely an example of a short cut adopted in the course of evolution, and replacing the original production of a branch in the axil of each carpellary scale. Eichler, one of the chief supporters of the simpler view, does not recognize in the inverse orientation of the vascular bundles an argument in support of the axillary bud theory, but points out that the seminiferous scale, being an outgrowth from the surface of the carpellary scale, would, like outgrowths from an ordinary leaf, naturally have its bundles inversely orientated. In such cone-scales as show little or no external indication of being double in origin, e.g., *Araucaria* (Fig. 15, D), *Sequoia*, &c., there are always two sets of bundles; the upper set, having the phloem uppermost, as in the seminiferous scale of *Abies* or *Pinus*, are regarded as belonging to the outgrowth from the carpellary scale and specially developed to supply the ovules. Monstrous cones are fairly common; these in some instances lend support to the axillary bud theory, and it has been said that this theory owes its existence to evidence furnished by abnormal cones. It is difficult to estimate the value of abnormalities as evidence bearing on morphological interpretation; the chief danger lies perhaps in attaching undue weight to them, but there is also a risk of minimizing their importance. Monstrosities at least demonstrate possible lines of development, but when the abnormal forms of growth in various directions are fairly evenly balanced, trustworthy deductions become difficult. The occurrence of buds in the axils of carpellary scales may, however, simply mean that buds, which are usually undeveloped in the axils of sporophylls, occasionally afford evidence of their existence. Some monstrous cones lend no support to the axillary bud theory. In *Larix* the axis of the cone often continues its growth; similarly in *Cephalotaxus* the cones are often proliferous. (In rare cases the proliferated portion produces male flowers in the leaf-axils.) In *Larix* the carpellary scale may become leafy, and the seminiferous scale may disappear. Androgynous cones may be produced, as in the cone of *Pinus rigida* (Fig. 16), in which the lower part bears stamens and the upper portion carpellary and seminiferous scales. An interesting case has been figured by Masters, in which scales of a cone of *Cupressus Lawsoniana* bear ovules on the upper surface and stamens on the lower face. One argument that has been adduced in support of the axillary bud theory is derived from the Palæozoic type *Cordaites*, in which each ovule occurs on an axis borne in the axil of a bract. The whole question is still unsolved, and perhaps insoluble. *Cordaites* is an extinct type which in certain respects resembles *Ginkgo*, Cycads, and the Araucarieæ, but its agreement with true Conifers is probably too remote to justify our attributing much weight to the bearing of the morphology of its female flowers on the interpretation of that of the Coniferæ. The greater simplicity of the Eichler theory may prejudice us in its favour, but, on the other hand, the arguments advanced in favour of the axillary bud theories are perhaps not sufficiently cogent to lead us to accept an explanation based chiefly on the uncertain evidence of monstrosities.

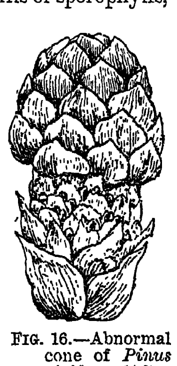

FIG. 16.—Abnormal cone of *Pinus rigida*. (After Masters.)

Micro-spores and mega-spores.

A pollen-grain when first formed from its mother-cell consists of a single cell; in this condition it may be carried to the nucellus of the ovule (e.g., *Taxus*, *Cupressus*, &c.), or more usually (*Pinus*, *Larix*, &c.) it reaches maturity before the dehiscence of the microsporangium. The nucleus of the microspore divides and gives rise to a small cell within the large cell, a second small cell is then produced; this is the structure of the ripe pollen-grain in some Conifers (*Taxus*, &c.). The large cell grows out as a pollen-tube; the second of the two small cells (body-cell) wanders into the tube, followed by the nucleus of the first small cell (stalk-cell). In *Taxus* the body-cell eventually divides into two, in which the products of division are of unequal size, the larger constituting the male generative cell, which fuses with the nucleus of the egg-cell. In *Juniperus* the products of division of the body-cell are equal and both function as male generative cells. In the Abietineæ cell-formation in the pollen-grain is carried farther. Three small cells occur inside the cavity of the microspore; two of them collapse and the third divides into two, forming a stalk-cell and a larger body-cell. The latter ultimately divides in the apex of the pollen-tube into two non-motile generative cells. The precise method of fertilization has been followed by V. H. Blackman, who also succeeded in showing that the nuclei of the sporophyte generation in *Pinus* contain twice as many chromosomes as the nuclei of the gametophyte. The ovule is usually surrounded by one integument, which projects beyond the tip of the nucellus as a wide-open lobed funnel, which at the time of pollination folds inwards, and so assists in bringing the pollen-grains on to the nucellus. In some Conifers (e.g., *Taxus*, *Cephalotaxus*, *Dacrydium*, &c.) the ordinary integument is partially enclosed by an arillus or second integument. It is held by some botanists (Celakovsky) that the seminiferous scale of the Abietineæ is homologous with the arillus or second integument of the Taxaceæ, but this view is too strained to gain general acceptance. In some species of *Araucaria* the nucellus itself projects beyond the open micropyle and receives the pollen-grains direct. During the growth of the cell which forms the megaspore the greater part of the nucellus is absorbed, except the apical portion, which persists as a cone above the megaspore; the partial disorganization of some of the cells in the centre of the nucellar cone forms an irregular cavity, which may be compared with the larger pollen-chamber of *Gingko* and the Cycads. In each ovule one megaspore comes to maturity, but, exceptionally, two may be present (e.g., *Pinus sylvestris*). The megaspore becomes filled with tissue (prothallus), and from some of the superficial cells archegonia are produced, usually three to five in number, but in rare cases ten to twenty may be present. An archegonium consists of a large oval egg-cell surmounted by a short neck composed of one or more tiers of cells, six to eight cells in each tier. Before fertilization the nucleus of the egg-cell divides and cuts off a ventral canal-cell; this cell may represent a second egg-cell. The egg-cells of the archegonia may be in lateral contact (*e.g.*, Cupressineæ) or separated from one another by a few cells of the prothallus, each ovum being immediately surrounded by a layer of cells distinguished by their granular contents and large nuclei. During the development of the egg-cell food material is transferred from these cells through the pitted wall of the ovum. The tissue at the apex of the megaspore grows slightly above the level of the archegonia, so that the latter come to lie in a shallow depression. In the process of fertilization the two male generative nuclei, accompanied by the pollen-tube nucleus and that of the stalk-cell, pass through an open pit at the apex of the pollen-tube into the protoplasm of the ovum. After fertilization the nucleus of the egg divides, the first stages of karyokinesis being apparent even before complete fusion of the male and female nuclei has occurred. The result of this is the production of four nuclei, which eventually take up a position at the bottom of the ovum and become separated from one another by vertical cell-walls; these nuclei divide again, and finally three tiers of cells are produced, four in each tier. In the Abietineæ the cells of the middle tier elongate and push the lowest tier deeper into the endosperm; the cells of the bottom tier may remain in lateral contact and produce together one embryo, or they may separate (*Pinus*, *Juniperus*, &c.) and form four potential embryos. The ripe albuminous seed contains a single embryo with two or more cotyledons; in some species of *Araucaria* (sect. *Colymbea*) the two cotyledons are partially fused, as in *Ginkgo*. The seeds of many Conifers are provided with large thin wings, consisting in some genera (e.g., *Pinus*) of the upper cell layers of the seminiferous scale, which have become detached and adhere loosely to the seed-coat as a thin membrane; this loose attachment may be of use to the seeds when they are blown against the branches of trees, in enabling them to fall away from the wing and drop to the ground. The seeds of some genera depend on animals for dispersal, the carpellary scale (*Microcachrys*) or the outer integument being brightly coloured and attractive. In some Abietineæ (e.g., *Pinus* and *Picea*)—in which the cone-scales persist for some time after the seeds are ripe—the cones hang down and so facilitate the fall of the seeds; in *Cedrus*, *Araucaria*, and *Abies* the scales become detached and fall with the seeds, leaving the bare vertical axis of the cone on the tree. In all cases, except some species of *Araucaria* (sect. *Colymbea*) the germination is epigean. The seedling plants of some Conifers (e.g., *Araucaria imbricata*) are characterized by a carrot-shaped hypocotyl, which doubtless serves as a food-reservoir.

Anatomy.

The roots of many Conifers possess a narrow band of primary xylem-tracheids with a group of narrow spiral protoxylem-elements at each end (diarch). A striking feature in the roots of several genera, excluding the Abietineæ, is the occurrence of thick and somewhat irregular bands of thickening on the cell walls of the cortical layer next to the endodermis. These bands, which may serve to strengthen the central cylinder, have been compared with the netting surrounding the delicate wall of an inflated balloon. It is not always easy to distinguish a root from a stem; in some cases (e.g., *Sequoia*) the primary tetrarch structure is easily identified in the centre of an old root, but in other

cases the primary elements are very difficult to recognize. The sudden termination of the secondary tracheids against the pith-cells may afford evidence of root-structure as distinct from stem-structure, in which the radial rows of secondary tracheids pass into the irregularly-arranged primary elements next the pith. The annual rings in a root are often less clearly marked than in the stem, and the xylem-elements are frequently larger and thinner. The primary vascular bundles in a young conifer stem are collateral, and, like those of a Dicotyledon, they are arranged in a circle round a central pith and enclosed by a common endodermis. It is in the nature of the secondary xylem that the Coniferales are most readily distinguished from the Dicotyledons and Cycadaceæ; the wood is homogeneous in structure, consisting almost entirely of tracheids with circular or polygonal bordered pits on the radial walls, more particularly in the late summer wood. In many genera xylem-parenchyma is present, but never in great abundance. A few Dicotyledons, e.g., *Drimys* (Magnoliaceæ) closely resemble Conifers in the homogeneous character of the wood, but in most cases the presence of large spring vessels, wood-fibres, and abundant parenchyma affords an obvious distinguishing feature.

The abundance of petrified coniferous wood in rocks of various ages has led many botanists to investigate the structure of modern genera with a view to determining how far anatomical characters may be used as evidence of generic distinctions. There are a few well-marked types of wood which serve as convenient standards of comparison, but these cannot be used except in a few cases to distinguish individual genera. The genus *Pinus* serves as an illustration of wood of a distinct type characterized by the absence of xylem-parenchyma, except such as is associated with the numerous resin-canals that occur abundantly in the wood, cortex, and medullary rays; the medullary rays are composed of parenchyma and of horizontal tracheids with irregular ingrowths from their walls. In a radial section of a Pine stem each ray is seen to consist in the median part of a few rows of parenchymatous cells with large oval simple pits in their walls, accompanied above and below by horizontal tracheids with bordered pits. The pits in the radial walls of the ordinary xylem-tracheids occur in a single row or in a double row, of which the pits are not in contact, and those of the two rows are placed on the same level. The medullary rays usually consist of a single tier of cells, but in the *Pinus* type of wood broader medullary rays also occur and are traversed by horizontal resin-canals. In the wood of *Cupressus*, *Cedrus*, *Abies*, and several other genera, parenchymatous cells occur in association with the xylem-tracheids and take the place of the resin-canals of other types. In the Araucarian type of wood (*Araucaria* and *Agathis*) the bordered pits, which occur in two or three rows on the radial walls of the tracheids, are in mutual contact and polygonal in shape, the pits of the different rows are alternate and not on the same level; in this type of wood the annual rings are often much less distinct than in *Cupressus*, *Pinus*, and other genera. In *Taxus*, *Torreya* (North America), and *Cephalotaxus* the absence of resin-canals and the presence of spiral thickening-bands in the tracheids constitute well-marked characteristics. An examination of the structure of the wood of branches, stems, and roots of the same species or individual usually reveals a fairly wide variation in some of the characters, such as the abundance and size of the medullary rays, the size and arrangement of pits, the presence of wood-parenchyma—characters to which undue importance has often been attached in systematic anatomical work. The phloem consists of sieve-tubes, with pitted areas on the lateral as well as on the inclined terminal walls, phloem-parenchyma, and, in some genera, fibres. In the Abietineæ the phloem consists of parenchyma and sieve-tubes only, but in most other forms tangential rows of fibres occur in regular alternation with the parenchyma and sieve-tubes. The characteristic companion-cells of Angiosperms are represented by phloem-parenchyma cells with albuminous contents; other parenchymatous elements of the bast contain starch or crystals of calcium oxalate. When tracheids occur in the medullary rays of the xylem these are replaced in the phloem-region by irregular parenchymatous cells known as albuminous cells. Resin-canals, which occur abundantly in the xylem, phloem, or cortex, are not found in the wood of the Yew. *Cephalotaxus* (Taxeæ) is also peculiar in having resin-canals in the pith (cf. *Ginkgo*). One form of *Cephalotaxus* is characterized by the presence of short tracheids in the pith, in shape like ordinary parenchyma, but in the possession of bordered pits and lignified walls agreeing with ordinary xylem-tracheids; it is probable that these short tracheids serve as reservoirs for storing rather than for conducting water. The vascular bundle entering the stem from a leaf with a single vein passes by a more or less direct course into the central cylinder of the stem, and does not assume the girdle-like form characteristic of the cycadean leaf-trace. In species of which the leaves have more than one vein (e.g., *Araucaria imbricata*, &c.) the leaf-trace leaves the stele of the stem as a single bundle which splits up into several strands in its course through the cortex. The leaf-trace in the Coniferales is simple in its course through the stem, differing in this respect from the double leaf-trace of *Ginkgo*. The anatomical characters of leaves most useful for diagnostic purposes are the position of the stomata, the presence and arrangement of resin-canals, the structure of the mesophyll and vascular bundles. The presence of hypodermal fibres is another feature worthy of note, but the occurrence of these elements is too closely connected with external conditions to be of much systematic value. A pine needle grown in continuous light differs from one grown under ordinary conditions in the absence of hypodermal fibres, in the absence of the characteristic infoldings of the mesophyll cell-walls, in the smaller size of the resin-canals, &c. The endodermis in *Pinus*, *Picea*, and many other genera is usually a well-defined layer of cells enclosing the vascular bundles, and separated from them by a tissue consisting in part of ordinary parenchyma and to some extent of isodiametric tracheids; but this tissue, usually spoken of as the pericycle, is in direct continuity with other stem-tissues as well as the pericycle. The occurrence of short tracheids in close proximity to the veins is a characteristic of coniferous leaves; these elements assume two distinct forms—(1) the short isodiametric tracheids (transfusion-tracheids) closely associated with the veins; (2) longer tracheids extending across the mesophyll at right angles to the veins, and no doubt functioning as representatives of lateral veins. It has been suggested that transfusion-tracheids represent, in part at least, the centripetal xylem, which forms a distinctive feature of cycadean leaf-bundles; these short tracheids form conspicuous groups laterally attached to the veins in *Cunninghamia*, abundantly represented in a similar position in the leaves of *Sequoia*, and scattered through the so-called pericycle in *Pinus*, *Picea*, &c. It is of interest to note the occurrence of precisely similar elements in the mesophyll of *Lepidodendron* leaves. An anatomical peculiarity in the veins of *Pinus* and several other genera is the continuity of the medullary rays, which extend as continuous plates from one end of the leaf to the other. The mesophyll of *Pinus* and *Cedrus* is characterized by its homogeneous character and by the presence of infoldings of the cell-walls. In many leaves, e.g., *Abies*, *Tsuga*, *Larix*, &c., the mesophyll is heterogeneous, consisting of palisade and spongy parenchyma. In the leaves of *Araucaria imbricata*, in which palisade-tissue occurs in both the upper and lower part of the mesophyll, the resin-canals are placed between the veins; in some species of *Podocarpus* (sect. *Nageia*) a canal occurs below each vein; in *Tsuga*, *Torreya*, *Cephalotaxus*, *Sequoia*, &c., a single canal occurs below the midrib; in *Larix*, *Abies*, &c., two canals run through the leaf parallel to the margins. The stomata are frequently arranged in rows, their position being marked by two white bands of wax on the leaf-surface.

Distribution.

The chief home of the Coniferales is in the northern hemisphere, where certain species occasionally extend beyond the Arctic circle and penetrate beyond the northern limit of dicotyledonous trees. Wide areas are often exclusively occupied by Conifers, which give the landscape a sombre aspect, suggesting a comparison with the forest vegetation of the Coal period. South of the tree-limit a belt of Conifers stretches across North Europe, Siberia, and Canada. In Northern Europe this belt is characterized by such species as *Picea excelsa* (Spruce), which extends south to the mountains of the Mediterranean region; *Pinus sylvestris* (Scottish Fir), reaching from the far north to Western Spain, Persia, and Asia Minor; *Juniperus communis*, &c. In North Siberia *Pinus Cembra* (Cembra or Arolla Pine) has a wide range; also *Abies Sibirica* (Siberian Silver Fir), *Larix Sibirica*, and *Juniperus sabina* (Savin). In the North American area *Picea alba*, *P. nigra*, *Larix Americana*, *Abies balsamea* (Balsam Fir), *Thuja Canadensis* (Hemlock Spruce), *Pinus Strobus* (Weymouth Pine), *Thuja occidentalis* (White Cedar), *Taxus Canadensis* are characteristic species. In the Mediterranean region occur *Cupressus sempervirens*, *Pinus Pinea* (Stone Pine), species of Juniper, *Cedrus atlantica*, *C. Libani*, *Callitris quadrivalvis*, *Pinus montana*, &c. Several Conifers of economic importance are abundant on the Atlantic side of North America—*Juniperus Virginiana* (Red Cedar, used in the manufacture of lead pencils and extending as far south as Florida), *Taxodium distichum* (Swamp Cypress), *Pinus rigida* (Pitch Pine), *P. mitis* (Yellow Pine), *P. tæda*, *P. palustris*, &c. On the west side of the American continent Conifers play a still more striking rôle; among them are *Chamæcyparis nutkaensis*, *Picea sitchensis*, *Libocedrus decurrens*, *Pseudotsuga Douglasii* (Douglas Fir), *Sequoia sempervirens*, *S. gigantea* (the only two surviving species of this generic type are now confined to a few localities in California, but were formerly widely spread in Europe and elsewhere), *Pinus Coulteri*, *P. Lambertiana*, &c. Farther south, a few representatives of such genera as *Abies*, *Cupressus*, *Pinus*, and Juniper are found in the Mexican Highlands, tropical America, and the West Indies. In the Far East Conifers are richly represented; among them occur *Pinus densiflora*, *Cryptomeria japonica*, *Cephalotaxus*, species of *Abies*, *Larix*, *Thujopsis*, *Sciadopitys verticillata*, *Pseudolarix Kaempferi*, &c. In the Himalaya occur *Cedrus deodara*, *Taxus*, species of *Cupressus*, *Pinus excelsa*, *Abies Webbiana*, &c. *Libocedrus tetragona*, *Fitzroya patagonica*, *Araucaria brasiliensis*, *A. imbricata*,

Saxegothœa, and others are met with in the Andes and other regions in South America. *Athrotaxis* and *Microcachrys* are characteristic Australian types. *Phyllocladus* occurs also in New Zealand, and species of *Dacrydium*, *Araucaria*, *Agathis*, and *Podocarpus* are represented in Australia, New Zealand, and the Malay regions.

Gnetales.—These are trees or shrubs with simple leaves. The flowers are diœcious, rarely monœcious, provided with one or two perianths. The wood is characterized by the presence of vessels in addition to tracheids. There are no resin-canals. The three existing genera usually spoken of as members of the Gnetales differ from one another more than is consistent with their inclusion in a single family; we may therefore better express their diverse characters by regarding them as types of three separate families—(1) *Ephedroideœ*, genus *Ephedra;* (2) *Welwitschioideœ*, genus *Welwitschia;* (3) *Gnetoideœ*, genus *Gnetum*. Our knowledge of the Gnetales leaves much to be desired, but such facts as we possess would seem to indicate that this group is of special importance as foreshadowing, more than any other Gymnosperms, the Angiospermous type. In the more heterogeneous structure of the wood and in the possession of true vessels the Gnetales agree closely with the higher Flowering Plants. It is of interest to note that the leaves of *Gnetum*, while typically Dicotyledonous in appearance, possess a Gymnospermous character in the continuous and plate-like medullary rays of their vascular bundles. The presence of a perianth is a feature suggestive of an approach to the floral structure of Angiosperms; the prolongation of the integument furnishes the flowers with a substitute for a stigma and style. The genus *Ephedra*, with its prothallus and archegonia, which are similar to those of other Gymnosperms, may be safely regarded as the most primitive of the Gnetales. In *Welwitschia* also the megaspore is filled with prothallus-tissue, but single egg-cells take the place of archegonia. In certain species of *Gnetum* described by Karsten the megaspore contains a peripheral layer of protoplasm, in which scattered nuclei represent the female reproductive cells; in *Gnetum Gnemon* a similar state of things exists in the upper half of the megaspore, while the lower half agrees with the megaspore of *Welwitschia* in being full of prothallus-tissue, which serves merely as a reservoir of food. Lotsy has described the occurrence of special cells at the apex of the prothallus of *Gnetum Gnemon*, which he regards as imperfect archegonia (Fig. 17, C, *a*); he suggests they may represent vestigial structures pointing back to some ancestral form beyond the limits of the present group. The Gnetales probably had a separate origin from the other Gymnosperms; they carry us nearer to the Angiosperms, but we have as yet no satisfactory evidence that they represent a stage in the direct line of Angiospermic evolution. It is not improbable that the three genera of this ancient phylum survive as types of a blindly-ending branch of the Gymnosperms; but be that as it may, it is in the Gnetales more than in any other Gymnosperms that we find features which help us to obtain a dim prospect of the lines along which the Angiosperms may have been evolved.

Ephedra.—This genus is the only member of the Gnetales represented in Europe. Its species, which are characteristic of warm temperate latitudes, are usually much-branched shrubs. The finer branches are green, and bear a close resemblance to the stems of *Equisetum* and to the slender twigs of *Casuarina;* the surface of the long internodes is marked by fine longitudinal ribs, and at the nodes are borne pairs of inconspicuous scale-leaves. The flowers are small, and borne on axillary shoots. A single male flower consists of an axis enclosed at the base by an inconspicuous perianth formed of two concrescent leaves and terminating in two, or as many as eight, shortly stalked or sessile anthers. The female flower is enveloped in a closely fitting sac-like investment, which must be regarded as a perianth; within this is an orthotropous ovule surrounded by a single integument prolonged upwards as a beak-like micropyle. The flower may be described as a bud bearing a pair of leaves which become fused and constitute a perianth, the apex of the shoot forming an ovule. In function the perianth may be compared with a unilocular ovary containing a single ovule; the projecting integument, which at the time of pollination secretes a drop of liquid, serves the same purpose as the style and stigma of an angiosperm. The megaspore is filled with tissue as in typical Gymnosperms, and from some of the superficial cells 3 to 5 archegonia are developed, characterized by long multicellular necks. The archegonia are separated from one another, as in *Pinus*, by some of the prothallus-tissue, and the cells next the egg-cells (tapetal layer) contribute food-material to their development. After fertilization, some of the uppermost bracts below each flower become red and fleshy; the perianth develops into a woody shell, while the integument remains membranous. In some species of *Ephedra*, e.g., *E. altissima*, the fertilized eggs grow into tubular proembryos, from the tip of each of which embryos begin to be developed, but one only comes to maturity. In *Ephedra helvetica*, as described by Jaccard, no proembryo or suspensor is formed; but the most vigorous fertilized egg, after undergoing several divisions, becomes attached to a tissue, termed the columella, which serves the purpose of a primary suspensor; the columella appears to be formed by the lignification of certain cells in the central region of the embryo-sac. At a later stage some of the cells in the upper (micropylar) end of the embryo divide and undergo considerable elongation, serving the purpose of a secondary suspensor. The secondary wood of *Ephedra* consists of tracheids, vessels, and parenchyma; the vessels are characterized by their wide lumen and by the large simple or slightly-bordered pits on their oblique end-walls.

Gnetum.—This genus is represented by several species, most of which are climbing plants, both in tropical America and in warm regions of the Old World. The leaves, which are borne in pairs at the tumid nodes, are oval in form and have a Dicotyledonous type of venation. The male and female inflorescences have the form of simple or paniculate spikes. The spike of an inflorescence bears whorls of flowers at each node in the axils of concrescent bracts accompanied by numerous sterile hairs (paraphyses); in a male inflorescence numerous flowers occur at each node, while in a female inflorescence the number of flowers at each node is much smaller. A male flower consists of a single angular perianth, through the open apex of which the flower-axis projects as a slender column terminating in two anthers. The female flowers,

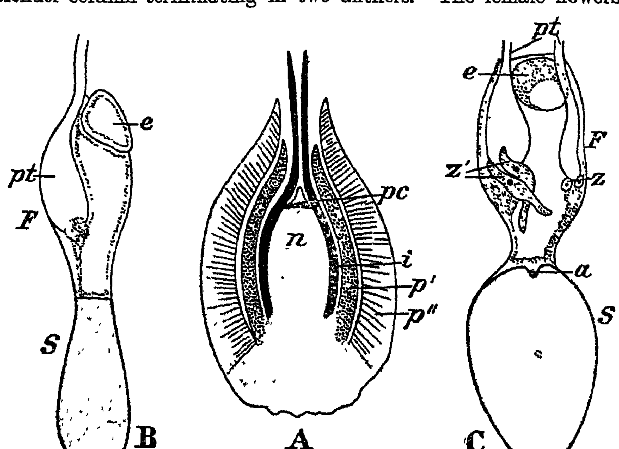

Fig. 17.—*Gnetum Gnemon.* A, female flower (*n*, nucellus; *pc*, pollen-chamber; *i*, integument; *p'*, inner perianth; *p''*, outer perianth). B, C, megaspore (*a*, imperfect archegonia; *e*, partially developed megaspore; *F*, fertile half; *S*, sterile half; *pt*, pollen-tube; *z*, zygote; *z'*, prothallus). (After Lotsy.)

which are more complex in structure, are of two types, complete and incomplete; the latter occur in association with male flowers in a male inflorescence. A complete female flower consists of a nucellus (Fig. 17, A, *n*), surrounded by a single integument (Fig. 17, A, *i*), prolonged upwards as a narrow tube and succeeded by an inner and an outer perianth (Fig. 17, A, *p'* and *p''*). The whole flower may be looked upon as an adventitious bud bearing two pairs of leaves; each pair becomes concrescent and forms a perianth, the apex of the shoot being converted into an orthotropous ovule. The incomplete female flowers are characterized by the almost complete suppression of the inner perianth. Several embryo-sacs (megaspores) are present in the nucellus of a young ovule, but one only attains full size, the smaller and partially developed megaspores (Fig. 17, B and C, *e*) being usually found in close association with the surviving and fully-grown megaspore. In *Gnetum Gnemon*, as described by Lotsy, a mature embryo-sac contains in the upper part (micropylar end) a large central vacuole and a peripheral layer of protoplasm, including several nuclei, which take the place of the archegonia of *Ephedra;* the lower part (chalazal end) of the embryo-sac, separated from the upper by a constriction, is full of parenchyma, which may be regarded as a prothallus. The upper part of the megaspore may be spoken of as the fertile half (Fig. 17, B and C, *F*), and the lower part, which serves only as food-reservoir for the growing embryo, may be termed the sterile half (Fig. 17, B and C, *S*). At the time of pollination the long tubular integument secretes a drop of fluid at its apex, which holds the pollen-grains, brought by the wind, or possibly to some extent by insect agency, and by evaporation these are drawn on to the top of the nucellus, where partial disorganization of the cells has given rise to an irregular pollen-chamber (Fig. 17, A, *pc*). The pollen-tube, containing two generative and one vegetative nucleus, pierces the wall of the megaspore and then becomes swollen (Fig. 17, B and C, *pt*); finally the two generative nuclei pass out of the tube and fuse with two of the nuclei in the fertile half of the megaspore. As the result of fertilization, the fertilized nuclei of the megaspore become surrounded by a cell-wall, and constitute zygotes, which may attach themselves either to the wall

of the megaspore or to the end of a pollen-tube (Fig. 17, C, z and z'); they then grow into long tubes or proembryos, which make their way towards the prothallus (C, z'), and eventually embryos are formed from the ends of the proembryo tubes. One embryo only comes to maturity. The embryo of *Gnetum* forms an outgrowth from the hypocotyl, which serves as a feeder and draws nourishment from the prothallus. The fleshy outer portion of the seed is formed from the outer perianth, the woody shell being derived from the inner perianth. The climbing species of *Gnetum* are characterized by the production of several concentric cylinders of secondary wood and bast, the additional cambium-rings being products of the pericycle, as in *Cycas* and *Macrozamia*. The structure of the wood agrees in the main with that of *Ephedra*.

Welwitschia.—This is by far the most remarkable member of the Gnetales, both as regards habit and the form of its flowers. In a supplement to the systematic work of Engler and Prantl the well-known name *Welwitschia*, instituted by Hooker in 1864 in honour of Welwitsch, the discoverer of the plant, is superseded by that of *Tumboa*, originally suggested by Welwitsch; but the more familiar name will, it is hoped, continue in general use as the recognized generic designation. *Welwitschia* is confined to certain localities in Damaraland on the west coast of tropical South Africa. A well-grown plant projects less than a foot above the surface of the ground; the stem, which may have a circumference of more than 12 feet, terminates in a depressed crown resembling a circular table with a median groove across the centre and prominent broad ridges concentric with the margin. The thick tuberous stem becomes rapidly narrower, and passes gradually downwards into a tap-root. A pair of small strap-shaped leaves succeed the two cotyledons of the seedling, and persist as the only leaves during the life of the plant; they retain the power of growth in their basal portion, which is sunk in a narrow groove near the edge of the crown, and the tough lamina, 6 feet in length, becomes split into narrow strap-shaped or thong-like strips which trail on the ground. Numerous circular pits occur on the concentric ridges of the depressed and wrinkled crown, marking the position of former inflorescences borne in the leaf-axil at different stages in the growth of the plant. An inflorescence has the form of a dichotomously-branched cyme bearing small erect cones; those containing the female flowers attain the size of a fir-cone, and are scarlet in colour. Each cone consists of an axis, on which numerous broad and thin bracts are arranged in regular rows; in the axil of each bract occurs a single flower; a male flower is enclosed by two opposite pairs of leaves, forming a perianth surrounding a central sterile ovule encircled by a ring of stamens united below, but free distally as short filaments, each of which terminates in a trilocular anther. The integument of the sterile ovule is prolonged above the nucellus as a spirally-twisted tube expanded at its apex into a flat stigma-like organ. A complete and functional female flower consists of a single ovule with two integuments, the inner of which is prolonged into a narrow tubular micropyle, like that in the flower of *Gnetum*. The megaspore of *Welwitschia* is filled with a prothallus-tissue before fertilization, and some of the prothallus-cells function as egg-cells; these grow upwards as long tubes into the apical region of the nucellus, where they come into contact with the pollen-tubes. After the egg-cells have been fertilized by the non-motile male cells they grow into tubular proembryos, producing terminal embryos. The stem is traversed by numerous collateral bundles, which have a limited growth, and are constantly replaced by new bundles developed from strands of secondary meristem. One of the best-known anatomical characteristics of the genus is the occurrence of numerous spindle-shaped or branched fibres with enormously-thickened walls studded with crystals of calcium oxalate.

Gympie, goldfield municipality, in the county of March, Queensland, Australia, 107 miles north of Brisbane, with which it is connected by rail, and 61 miles south by rail from Maryborough. Numerous gold mines are worked in the district. The total value of the gold output to the end of 1899 amounted to £8,400,000. It also abounds in copper, silver, antimony, cinnabar, bismuth, and nickel. Extensive coal beds, as yet unworked, lie 40 miles to the north at Miva. Population (1871), 5800; (1901), 11,959.

"Gyp." See MARTEL, COMTESSE DE.

Gyroscope and **Gyrostat.**—The Gyroscope and Gyrostat are scientific models or instruments designed to illustrate experimentally the dynamics of rotating bodies, such as the spinning top, hoop, and bicycle, and also the precession of the equinoxes.

The instruments may be distinguished by calling the one a Gyroscope when the rotating wheel or disc is mounted in gimbals so that the principal axis of rotation always passes through a fixed point (Fig. 1). It can be made to imitate the motion of a spinning top of which the point is placed in a smooth agate cup, as in Maxwell's Dynamical Top (Figs. 2, 3) (*Collected Works*, i. p. 248). A bicycle wheel, with one of the ball bearings placed in a cup, can also be made to serve.

Gyroscope.

The Gyrostat is an instrument designed by Lord Kelvin (*Natural Philosophy*, § 345) to illustrate the more complicated state of motion of a spinning body when free to wander about on a horizontal plane, like a top spun on the pavement, or a hoop or bicycle on the road. It consists essentially of a massive fly-wheel concealed in a metal casing, and its behaviour on a table, or with various modes of suspension or support, serves to illustrate the curious reversal of the ordinary laws of statical equilibrium due to the *gyrostatic domination* of the interior invisible fly-wheel, when rotated rapidly (Fig. 4).

Gyrostat.

The toy shown in Figs. 5 and 6, which can be bought for one shilling, is acting as a gyroscope in Fig. 5 and a gyrostat in Fig. 6.

The Gyroscope, as represented in Fig. 2 by Maxwell's Dynamical Top, is provided with screws by which the centre of gravity can be brought into coincidence with the point of support. It can then be used to illustrate Poinsot's theory of the motion of a body under no forces, the gyroscope being made kinetically unsymmetrical by a setting of the screws. The discussion of this movement is required for Jacobi's theorems on the allied motion of a top and of a body under no forces (Poinsot, *Théorie nouvelle de la rotation des corps*, Paris, 1857; Jacobi, *Werke*, ii., Note B, p. 476).

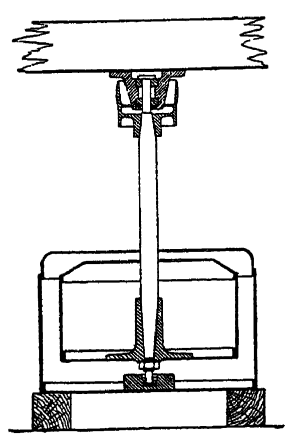

Fig. 9.

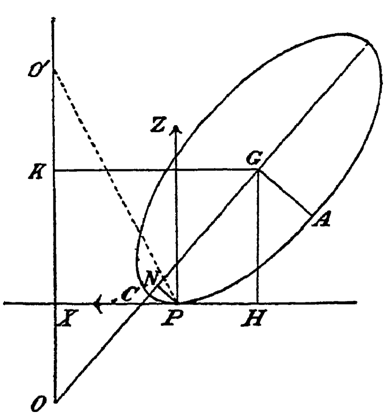

Fig. 12.

To imitate the movement of the top the centre of gravity G is displaced from the point of support O so as to give a preponderance; and the complete solution of the dynamical problem can now be carried out by single-valued elliptic functions, but only in the case of the *symmetrical* top, as it is called when OG is a principal axis of kinetic symmetry such that the moment of inertia about any axis OA at right angles to OG is the same. If this condition is not satisfied the top is called the *general* or *unsymmetrical* top, and the motion is complicated to such an extent as to have baffled the powers of mathematics, except for some special cases, discussed by Weierstrass, Kowalevski, Hess, Jukovsky, and others, principally the Russian mathematicians.

Symmetrical top.

Unsymmetrical top.

The motion of the Gyrostat, even if kinetically symmetrical, introduces analytical complications similar to those of the general unsymmetrical top, and here, too, we must await mathematical progress for a complete solution.

Contrasted mathematically, the motion of the Gyroscope, if symmetrical, can be expressed completely by the Elliptic Functions, but the Gyrostat and unsymmetrical top require functions of a higher order of complexity for a complete solution.

1. The physical constants of a given symmetrical top, expressed in C.G.S. units, which are employed in the subsequent formulæ, are denoted by M, h, C, and A. M is the weight in grammes (g) as given by the number of gramme weights which equilibrate the top when weighed in a balance; h is the distance OG in centimetres (cm.) between G the centre of gravity and O the point of support, and Mh may be called the preponderance; thus Mgh (dyne-cm.) is the moment of gravity about O when the axis OG is horizontal, Mgh sin θ being the moment when the axis OG makes an angle θ with the vertical, and $g=981$ (cm./s^2) on the average; C is the moment of inertia of the top about OG, and A about any axis through O at right angles to OG, both measured in g-cm.^{2}.

To measure A experimentally, swing the top freely about O in small plane oscillations, and determine the length, l cm., of the equivalent simple pendulum; then

$$(1)\qquad l=\frac{A}{Mh},\ A=Mhl.$$

Next make the top, or this simple pendulum, perform small conical revolutions, nearly coincident with the downward vertical position of equilibrium, and measure n, the mean angular velocity of the conical pendulum in radians / second; then

$$(2)\qquad n^2=\frac{g}{l}=\frac{Mgh}{A};$$

and $n/2\pi$ is the number of revolutions per second, $2\pi/n$ is the period of a revolution, in seconds.

2. In the popular explanation of the steady movement of the top at a constant inclination to the vertical, depending on the composition of angular velocities, such as given in Perry's *Spinning Tops*, or Worthington's *Dynamics of Rotation*, it is asserted that the moment of gravity is always generating an angular velocity about an axis OB perpendicular to the vertical plane GOC through the axis of the top OC; and this angular velocity, compounded with the resultant angular velocity about an axis OI, nearly coincident with OC, causes the axes OI and OC to keep taking up a new position by moving at right angles to the plane GOC, at a constant precessional angular velocity, say μ rad./sec., round the vertical OG (Fig. 7).

Steady motion of the top.

If, however, the axis OC is prevented from taking up this precessional velocity, the top at once falls down; thence all the ingenious attempts—for instance, in the swinging cabin of the Bessemer ship—to utilize the Gyroscope as a mechanical directive agency have always resulted in failure (*Engineer*, October 1874).

An experimental verification can be carried out with the Gyroscope in Fig. 1; so long as the vertical spindle is free to rotate in its socket, the rapidly rotating wheel will resist the impulse of tapping on the gimbal by moving to one side; but when the pinch screw prevents the rotation of the vertical spindle in the massive pedestal, this resistance to the tapping at once disappears, provided the friction of the table prevents the movement of the pedestal.

Familiar instances of the same principles are observable in the movement of a hoop, or in the steering of a bicycle; it is essential that the handles of the bicycle should be free to rotate to secure the stability of the movement.

The bicycle wheel, employed as a spinning top, can also be carried round a room held by the ball bearings, and will thus, when rotated rapidly, convey a distinct muscular impression of resistance to change of direction.

3. A demonstration, depending on the elementary principles of Dynamics, of the exact conditions required for the axis OC of a spinning top to spin steadily at a constant inclination θ to the vertical OG, is given here before proceeding to the more complicated question of the general motion, when θ, the inclination of the axis, is varying by nutation.

Elementary demonstration of the condition of steady motion.

It is a fundamental principle in Dynamics that if OH is a vector representing to scale the angular momentum of a system, and if Og is the vector representing the axis of the impressed couple or torque, then OH will vary so that the velocity of H is represented to scale by the impressed couple Og, and if the top is moving freely about O,

$$(1)\qquad Og=Mgh\sin\theta.$$

In the case of the steady motion of the top, the vector OH lies in the vertical plane GOC, in OK suppose (Fig. 7), and has a component OG=G about the vertical and a component OC=G′, suppose, about the axis OC; and G′=CR, if R denotes the angular velocity of the top with which it is spun about OC.

If μ denotes the constant precessional angular velocity of the vertical plane GOC, the components of angular velocity and momentum about OA are $\mu\sin\theta$ and $A\mu\sin\theta$, OA being perpendicular to OC in the plane GOC; so that the vector OK has the components

$$(2)\qquad OC=G',\ \text{and}\ CK=A\mu\sin\theta,$$

and the horizontal component

$$(3)\qquad GK=OC\sin\theta-CK\cos\theta$$
$$=G'\sin\theta-A\mu\sin\theta\cos\theta.$$

The velocity of K being equal to the impressed couple Og,

$$(4)\qquad Mgh\sin\theta=\mu\,.\,GK=\sin\theta\,(G'\mu-A\mu^2\cos\theta),$$

and dropping the factor sin θ,

$$(5)\qquad A\mu^2\cos\theta-G'\mu+Mgh=0,$$

the condition for steady motion.

Solving this as a quadratic in μ, the roots μ_1, μ_2 are given by

$$(6)\qquad \mu_1,\ \mu_2=\frac{G'}{2A}\sec\theta\left[1\mp\sqrt{(1-\frac{4AMgh}{G'^2}\cos\theta)}\right];$$

and the minimum value of G′=CR for real values of μ is given by

$$(7)\qquad \frac{G'^2}{4AMgh}=\cos\theta,\ \frac{CR}{An}=2\sqrt{(\cos\theta)};$$

for smaller values of R the top cannot spin steadily at the inclination θ to the upward vertical.

Interpreted geometrically

$$(8)\qquad \mu=\frac{Mgh\sin\theta}{GK}=\frac{CK}{A\sin\theta},$$

$$(9)\qquad CK\,.\,KG=AMgh\sin^2\theta;$$

and the maximum value of CK. KG is $\frac{1}{4}$OC^2 sin θ tan θ.

4. Suppose the top or gyroscope, instead of moving freely about the point O, is held in a ring or frame which is compelled to rotate about the vertical axis OG with constant angular velocity μ; then if N denotes the couple of reaction of the frame keeping the top from falling, acting in the plane GOC, equation (4) § 3 becomes modified into

Constrained motion of the gyroscope.

$$(1)\qquad Mgh\sin\theta-N=\sin\theta\,(G'\mu-A\mu^2\cos\theta),$$

$$(2)\qquad N=\sin\theta\,(A\mu^2\cos\theta-G'\mu+Mgh)$$
$$=A\sin\theta\cos\theta\,(\mu-\mu_1)\,(\mu-\mu_2);$$

and hence, as μ increases through μ_1 and μ_2, the sign of N can be determined, positive or negative, according as the tendency of the axis is to fall or rise.

When G′=CR is large, μ_2 is large, and

$$(3)\qquad \mu_1\approx\frac{Mgh}{G'}=\frac{An^2}{CR},$$

the same for all inclinations, and this is the precession observed in the spinning top and centrifugal machine.

If the axis of the top OC is pointing upwards, the precession is in the same direction as the rotation, and an increase of μ from μ_1 makes N negative, and the top rises; conversely a decrease of the precession μ causes the axis to fall (Perry, *Spinning Tops*, p. 48).

If the axis points downwards, as in the centrifugal machine with upper support, the precession is in the opposite direction to the rotation, and to make the axis approach the vertical position the precession must be reduced.

This is effected automatically in the Weston centrifugal machine (Fig. 9) by the friction of the indiarubber cushions above the support; or else the spindle is produced downwards below the drum a short distance, and turns in a hole in a weight resting on the bottom of the case, which weight is dragged round until the spindle is upright; this second

Centrifugal machine.

arrangement is more effective when liquids are treated in the drum, and wave action is set up (*The Centrifugal Machine*, C. A. Matthey).

Similar considerations apply to the stability of the whirling bowl in a cream-separating machine.

5. If the preponderance is absent, by making the C.G coincide with O, and if $A\mu$ is insensible compared with G',

(1) $$N = -G'\mu \sin\theta,$$

the formula which suffices to explain most gyroscopic action.

Gyroscopic action of railway wheels. Thus a train running round a curve experiences, in consequence of the rotation of the wheels, an increase of pressure Z on the outer rail, and a diminution Z on the inner, giving a couple, if a is the gauge,

(2) $$Za = G'\mu,$$

tending to help the centrifugal force to upset the train; and if c is the radius of the curve, b of the wheels, C their moment of inertia, and v the velocity of the train,

(3) $$\mu = \frac{v}{c},\ G' = C\frac{v}{b},$$

(4) $$Z = C\frac{v^2}{abc}\ \text{(dynes)},$$

so that Z is the fraction C/Mab of the centrifugal force Mv^2/c.

Model to illustrate drift in artillery. A gyroscope mounted axially in a small truck which runs on a model switchback road can be used to illustrate the drift from the vertical plane of fire observed with rifled projectiles.

With the right-handed rotation as usually imparted in artillery, the truck drifts to the $\left\{\begin{matrix}\text{left}\\\text{right}\end{matrix}\right\}$ on the $\left\{\begin{matrix}\text{convex}\\\text{concave}\end{matrix}\right\}$ part of the track, because the couple required for deflecting the axis of the gyroscope is supplied by the sidelong friction of the track on the wheels; and the tendency of the truck is to move against the direction of the applied force.

But the projectile in its trajectory with upward convexity drifts on the whole to the right, so that the real dynamical interpretation of drift in artillery must be sought elsewhere.

The gyroscopic action of dynamos, and other rapidly rotating machinery on a ship, due to its rolling and pitching, can be evaluated in a similar elementary manner (Worthington, *Dynamics of Rotation*).

6. If the axis OG is inclined at an angle α to the vertical, the equation (2) § 4 becomes

(1) $$N = \sin\theta\,(A\mu^2\cos\theta - G'\mu) + Mgh\sin(\theta - \alpha).$$

Suppose, for instance, that OG is parallel to the Earth's axis, and that the frame is fixed in the meridian; then α is the co-latitude, and μ is the angular velocity of the Earth, the square of which may be neglected; so that, putting $N=0$, $\theta - \alpha = E$,

(2) $$Mgh\sin E - G'\mu\sin(\alpha + E) = 0,$$

(3) $$\tan E = \frac{G'\mu\sin\alpha}{Mgh - G'\mu\cos\alpha} \approx \frac{G'\mu}{Mgh}\sin\alpha.$$

The barogyroscope. This is the theory of Gilbert's barogyroscope, described in Appell's *Mécanique rationelle*, ii. p. 387: it consists essentially of a rapidly rotated gyrostat, mounted on knife-edges by an axis perpendicular to its axis of rotation and pointing east and west; spun with considerable angular momentum G', and provided with a slight preponderance Mh, it should tilt to an angle E with the vertical, and thus demonstrate experimentally the rotation of the Earth.

Foucault's gyroscope. In Foucault's gyroscope (*Comptes Rendus*, 1852; Perry, p. 105) the preponderance is made zero, and the axis points to the pole, when free to move in the meridian.

Generally, if constrained to move in any other plane, the axis seeks the position nearest to the polar axis, like a dipping needle with respect to the magnetic pole. (*A gyrostatic working model of the magnetic compass*, by Sir W. Thomson. British Association Report, Montreal, 1884. A. S. Chessin, St Louis Academy of Science, January 1902.)

Gyroscopic horizon. A spinning top with a polished upper plane surface will provide an artificial horizon at sea, when the real horizon is obscured. The first instrument of this kind was constructed by Serson, and is described in the *Gentleman's Magazine*, vol. xxiv., 1754; also by Segner in his *Specimen theoriæ turbinum* (Halæ, 1755). The inventor was sent to sea by the Admiralty to test his instrument, but he was lost in the wreck of the *Victory*, 1744. A copy of the Serson top, from the royal collection, is now in the Museum of King's College, London. Troughton's Nautical Top (1819) is intended for the same purpose.

The instrument is in favour with French navigators; but it must be noticed that the horizon given by the top is inclined to the true horizon at the angle E given by equation (3) above; and if μ_1 is the precessional angular velocity as given by (3) § 4, and $T = 2\pi/\mu$, its period in seconds,

(4) $$\tan E = \frac{\mu}{\mu_1}\cos\text{lat} = \frac{T\cos\text{lat}}{86400},\ \text{or } E = \frac{\cos\text{lat}}{4\mu_1},$$

if E is expressed in minutes, taking $\mu = 2\pi/86400$; thus making the true latitude E nautical miles to the south of that given by the top (*Revue maritime*, 1890; *Comptes Rendus*, 1896).

Euler's coordinate angles. 7. In the ordinary treatment of the general theory of the gyroscope, the motion is referred to two sets of rectangular axes; the one Ox, Oy, Oz fixed in space, with Oz vertically upwards; and the other OX, OY, OZ fixed in the rotating wheel with OZ in the axis of figure OC.

The relative position of the two sets of axes is given by means of Euler's unsymmetrical angles θ, ϕ, ψ, such that the successive turning of the axes Ox, Oy, Oz through the angles (i) ψ about Oz, (ii) θ about OE, (iii) ϕ about OZ, brings them into coincidence with OX, OY, OZ, as shown in Fig. 10, representing the *concave* side of a spherical surface.

The component angular velocities about OD, OE, OZ are

(1) $$-\dot\psi\sin\theta,\ \dot\theta,\ \dot\phi + \dot\psi\cos\theta;$$

so that, denoting the components about OX, OY, OZ by P, Q, R,

(2) $$\begin{aligned} P &= \dot\theta\sin\phi - \dot\psi\sin\theta\cos\phi,\\ Q &= \dot\theta\cos\phi + \dot\psi\sin\theta\sin\phi,\\ R &= \dot\phi + \dot\psi\cos\theta. \end{aligned}$$

Consider, for instance, the motion of a fly-wheel of preponderance Mh, and equatoreal moment of inertia A, of which the axis OC is held in a light ring ZC at a constant angle γ with OZ, while OZ is held by another ring zZ, which constrains it to move round the vertical Oz at a constant inclination θ with constant angular velocity μ, so that

(3) $$\dot\theta = 0,\ \dot\psi = \mu;$$

(4) $$P = -\mu\sin\theta\cos\phi,\ Q = \mu\sin\theta\sin\phi,\ R = \dot\phi + \mu\cos\theta.$$

The components of angular velocity and momentum about OF, OY, are

(5) $$P\cos\gamma - R\sin\gamma,\ Q,\ \text{and } A(P\cos\gamma - R\sin\gamma),\ AQ,$$

so that, denoting the components of angular momentum of the fly-wheel about OC, OX, OY, OZ by K, h_1, h_2, h_3,

(6) $$h_1 = A(P\cos\gamma - R\sin\gamma)\cos\gamma + K\sin\gamma,$$

(7) $$h_2 = AQ,$$

(8) $$h_3 = -A(P\cos\gamma - R\sin\gamma)\sin\gamma + K\cos\gamma;$$

and the dynamical equation

(9) $$\frac{dh_3}{dt} - h_1Q + h_2P = N,$$

with K constant, and

(10) $$N = -Mgh\sin\gamma\cos zY = -Mgh\sin\gamma\sin\theta\sin\phi,$$

reduces to

(11) $$A\frac{d^2\phi}{dt^2}\sin\gamma - A\mu^2\sin\gamma\sin^2\theta\sin\phi\cos\phi + A\mu^2\cos\gamma\sin\theta\cos\theta\sin\phi - (K\mu - Mgh)\sin\theta\sin\phi = 0.$$

The positions of relative equilibrium are given by

(12) $$\sin\phi = 0,\ \text{and}\ \cos\phi = \frac{A\mu^2\cos\gamma\cos\theta - K\mu + Mgh}{A\mu^2\sin\gamma\sin\theta}.$$

For small values of μ the equation becomes

(13) $$A\frac{d^2\phi}{dt^2}\sin\gamma - (K\mu - Mgh)\sin\theta\sin\phi = 0,$$

so that $\phi = \pi$ or 0 gives the position of equilibrium, and the period of a small oscillation is $2\pi\sqrt{\{A\sin\gamma/(K\mu \sim Mgh)\sin\theta\}}$.

In the general case, denoting the periods of vibration about $\phi = \pi$, 0, and the sidelong position of equilibrium by $2\pi/(n_1, n_2, \text{or } n_3)$, we shall find

(14) $$n_1^2 = \frac{\sin\theta}{A\sin\gamma}\{K\mu - Mgh - A\mu^2\cos(\gamma - \theta)\},$$

(15) $$n_2^2 = \frac{\sin\theta}{A\sin\gamma}\{Mgh - K\mu + A\mu^2\cos(\gamma + \theta)\},$$

(16) $$n_3 = n_1 n_2/\mu\sin\theta.$$

The first integral of (11) gives

(17) $$\tfrac{1}{2}A\left(\frac{d\phi}{dt}\right)^2\sin\gamma + \tfrac{1}{2}A\mu^2\sin\gamma\sin^2\theta\cos^2\phi - A\mu^2\cos\gamma\sin\theta\cos\theta\cos\phi + (K\mu - Mgh)\sin\theta\cos\phi - H = 0,$$

and putting $\tan\frac{1}{2}\phi = z$, this reduces to

(18) $$\frac{dz}{dt} = n\sqrt{Z}$$

where Z is a quadratic in z^2, so that z is a Jacobian elliptic function of t, and we have

(19) $$\tan\tfrac{1}{2}\phi = C(\text{tn, dn, nc, or cn})nt,$$

according as the ring ZC performs complete revolutions, or oscillates about a sidelong position of equilibrium, or oscillates about the stable position of equilibrium $\phi = \pi$, or 0.

Suppose Oz is parallel to the Earth's axis, and μ is the diurnal rotation, the square of which may be neglected, then if Gilbert's barogyroscope of § 6 has the knife-edges turned in azimuth to make

an angle β with E. and W., we must put $\gamma=\frac{1}{2}\pi$, $\cos\theta=\sin\alpha\sin\beta$; and putting $\phi=\delta+\text{E}$, where δ denotes the angle between $\text{Z}z$ and the vertical plane $\text{Z}\zeta$ through the zenith ζ,

(20). $\sin\theta\cos\delta=\cos\alpha$, $\sin\theta\sin\delta=\sin\alpha\cos\beta$;

so that equations (9) and (10) for relative equilibrium reduce to

(21) $-\text{K}\mu\sin\theta\sin(\delta+\text{E})+\text{M}gh\sin\text{E}=0$,

and will change (3) § 6 into

(22) $$\tan\text{E}=\frac{\text{K}\mu\sin\alpha\cos\beta}{\text{M}gh-\text{K}\mu\cos\alpha}$$

(Gilbert, *Comptes Rendus*, 1882, p. 197).

8. In the general motion of the top, when the axis performs nutation, the vector OH of resultant angular momentum is no longer compelled to lie in the vertical plane GOC, OC being placed in OZ; but since the axis Og of the torque of gravity is always horizontal, H will describe a curve (a Poinsot herpolhode) in a fixed horizontal plane, at a height OG above O, the vertical vector OG representing the constant component G of angular momentum about the vertical.

General motion of the top.

The component G′ of the angular momentum of the top about its axis OC remains constant also, as there is nothing to alter it in the symmetrical top.

Expressed by Euler's angles θ and ψ, the vector OH has the components (Figs. 7 and 8)

$$\text{OC}=\text{G}',\ \text{CK}=\text{A}\sin\theta\frac{d\psi}{dt},\ \text{KH}=\text{A}\frac{d\theta}{dt}.$$

The velocity of H is equal to the torque of gravity $\text{M}gh\sin\theta$, perpendicular to the plane GOC, so that the *hodograph* of the curve of H (turned backwards through a right angle) is given by the vector $\text{M}gh\sin\theta e^{\psi i}$, and is therefore similar to the curve of the projection of C on a horizontal plane; so that, denoting the polar co-ordinates of H in the horizontal plane GHK by ρ and ϖ, the associated motion of the axis of the top is given by

(1) $$\text{M}gh\sin\theta e^{\psi i}=-i\frac{d}{dt}(\rho e^{\varpi i})$$

and loops in the curve of C correspond to undulations of H. Resolving in the radial direction GH for the curve of H,

(2) $$\frac{d\rho}{dt}=\text{M}gh\sin\theta\cos\text{GHK}=\text{M}gh\sin\theta\frac{\text{KH}}{\rho}$$

(3) $$\rho\frac{d\rho}{dt}=\text{AM}gh\sin\theta\frac{d\theta}{dt},$$

and integrating,

(4) $\frac{1}{2}\rho^2=\text{AM}gh(\text{E}-\cos\theta)$.

To make the equations homogeneous, put

(5) $\text{OG}=\delta,\ \text{OC}=\delta',\ 4\text{AM}gh=k^2$;

so that

(6) $\rho^2=\frac{1}{2}k^2(\text{E}-\cos\theta)$;

and denoting the perpendicular GK on the tangent at H by p,

(7) $p\sin\theta=\text{OC}-\text{OG}\cos\theta=\delta'-\delta\cos\theta$,

so that, eliminating θ,

(8) $$p^2=\frac{(\delta'-\delta\cos\theta)^2}{\sin^2\theta}=\frac{\{\delta'k^2-\delta(\text{E}k^2-2\rho^2)\}^2}{k^4-(\text{E}k^2-2\rho^2)^2}$$

(9) $$\rho^2-p^2=\frac{\text{R}}{k^4-(\text{E}k^2-2\rho^2)^2},$$

(10) $$\tan\text{KGH}=\frac{\sqrt{\text{R}}}{\delta'k^2-\delta(\text{E}k^2-2\rho^2)},$$

where

(11) $\text{R}=\rho^2\{k^4-(\text{E}k^2-2\rho^2)^2\}-\{\delta'k^2-\delta(\text{E}k^2-2\rho^2)\}^2$

and the diameter of curvature

(12) $$\frac{d\rho^2}{dp}=\frac{\frac{1}{2}k^2\text{E}\sin^3\theta}{\delta-\delta'\cos\theta}.$$

These will be found to be the equations which represent the characteristic geometrical properties of a Poinsot herpolhode, defined as the trace on a fixed tangent plane of the point of contact of a rolling quadric surface, moving about a fixed centre.

Thus, if $\delta=\pm\delta'$, as in Klein's *rosette curves* of the spinning top, in which the axis passes periodically through the highest or lowest vertical position, the quadric surface reduces to a plate, and the herpolhode is the projection of a geodesic line on a prolate spheroid.

In the steady motion of § 3 the rolling quadric surface is of revolution, and the top has a regular precession except when, as in § 4, the top is spun rapidly and K is close to C in Fig. 7; the rolling surface is now an attenuated rod-like figure, not necessarily of revolution, and a tremulous (*pseudo-regular*, Klein) precession of the top can ensue, such as would be generated if the top was spun rapidly and then dropped with its point in the cup O.

Darboux has shown that the motion of the axis of the top can be realized mechanically by means of an articulated hyperboloid, formed of rods placed along the generating lines and bound together at the points of crossing (Despeyrous, *Mécanique*, ii. p. 527). If O and H are at opposite ends of a diameter of this hyperboloid, and OG, OC are the generating lines through O, then as H is moved on the plane GHK along the herpolhode, keeping OG and the parallel generator through H vertical, the generating line OC will follow the motion of the axis of a top.

The curve of H on the rolling quadric is a line of curvature on an ellipsoid and hyperboloid of two sheets, confocal with the deformable hyperboloid (*Proceedings London Math. Society*, xxvi., xxvii.).

Since

(13) $\text{KH}^2=\text{GH}^2-\text{GK}^2$

(14) $$\text{A}^2\left(\frac{d\theta}{dt}\right)^2=2\text{AM}gh(\text{E}-\cos\theta)-\frac{(\text{G}'-\text{G}\cos\theta)^2}{\sin^2\theta},$$

and putting $\cos\theta=z,\ \frac{\text{M}gh}{\text{A}}=n^2,$

(15) $$\left(\frac{dz}{dt}\right)^2=2n^2\text{Z},$$

(16) $$\text{Z}=(\text{E}-z)(1-z^2)-\frac{(\text{G}'-\text{G}z)^2}{2\text{AM}gh}=(\text{E}-z)(1-z^2)-2\left(\frac{\delta'-\delta z}{k}\right)^2.$$

Denoting the roots of $\text{Z}=0$ by z_1, z_2, z_3, arranged in the order

(17) $z_1>1>z_2>z>z_3>-1$,

then with $\frac{d\theta}{dt}$ positive, $\frac{dz}{dt}$ negative, as in Fig. 7,

(18) $$nt=\int_z^{z_2}\frac{dz}{\sqrt{2\text{Z}}},$$

an elliptic integral of the first kind; and, by inversion, z is an elliptic function of t.

To make the reduction to Legendre's standard form, put

(19) $z=z_2\sin^2\phi+z_3\cos^2\phi$,

(20) $z-z_3=(z_2-z_3)\sin^2\phi$,

(21) $z_2-z=(z_2-z_3)\cos^2\phi$,

(22) $z_1-z=(z_1-z_3)\Delta^2\phi$,

(23) $$\kappa^2=\frac{z_2-z_3}{z_1-z_3},\ \kappa'^2=\frac{z_1-z_3}{z_1-z_3}.$$

Then

(24) $$nt=\sqrt{\left(\frac{2}{z_1-z_3}\right)}\int_\phi^{\frac{1}{2}\pi}\frac{d\phi}{\Delta\phi}=\sqrt{\left(\frac{2}{z_1-z_3}\right)}(\text{K}-\text{F}\phi).$$

(25) $$\text{F}\phi=\text{K}-mt,\ mt=\sqrt{\left(\frac{z_1-z_3}{2}\right)}nt.$$

In Jacobi's notation,

(26) $\phi=\text{am}(\text{K}-mt)$;

and in Gudermann's notation,

(27) $z=z_2\text{sn}^2(\text{K}-mt)+z_3\text{cn}^2(\text{K}-mt)$.

Denoting the roots of $\text{R}=0$ in (11) by ρ_1^2, ρ_2^2, ρ_3^2, then (18) becomes

(28) $$nt=\int_{\rho_2}^{\rho}\frac{kd\rho^2}{\sqrt{\text{R}}},$$

and

(29) $\rho^2=\rho_2^2\text{sn}^2(\text{K}-mt)+\rho_3^2\text{cn}^2(\text{K}-mt)$.

Again, resolving transversely to GH, or rather, taking the moment of the velocity V of H round G,

(30) $$p\text{V}=\rho^2\frac{d\varpi}{dt}=\text{O}g.\text{GK}=\text{M}gh\sin\theta.\text{GK},$$
$$=\text{M}gh(\text{G}'-\text{G}\cos\theta)=\tfrac{1}{2}nk(\delta'-\delta z);$$

so that, from (7)

(31) $$\text{V}=\tfrac{1}{2}nk\sin\theta=\tfrac{1}{2}\frac{n}{k}\sqrt{\{k^4-(\text{E}k^2-2\rho^2)^2\}},$$

(32) $$\frac{d\varpi}{dt}=\frac{\text{G}'-\text{G}z}{2\text{A}(\text{E}-z)},$$

(33) $$\varpi=\frac{\text{G}t}{2\text{A}}+\frac{\text{G}'-\text{EG}}{2\text{A}}\int\frac{dt}{\text{E}-z},$$
$$=\frac{\delta}{k}nt+\frac{\delta'-\text{E}\delta}{k}\int_z^{z_2}\frac{dz}{(\text{E}-z)\sqrt{2\text{Z}}},$$
$$=\frac{\delta}{k}nt+\tfrac{1}{2}\int_{\rho_2}^{\rho}\frac{(\delta'-\text{E}\delta)k^2\delta\rho^2}{\rho^2\sqrt{\text{R}}}$$

involving an elliptic integral of the third kind; (29) and (33) give the analytical determination of the curve of H.

Denoting the angle KGH by χ,

$$(34)\qquad \tan\chi=\frac{\mathrm{KH}}{\mathrm{GK}}=\frac{\mathrm{A}\sin\theta\frac{d\theta}{dt}}{\mathrm{GK}\sin\theta}=\frac{\sqrt{2\mathrm{AM}gh\mathrm{Z}}}{\mathrm{G}'-\mathrm{G}z},$$

$$(35)\qquad \sin\theta e^{\chi i}=\frac{2\frac{\delta'-\delta z}{k}+i\sqrt{2\mathrm{Z}}}{\sqrt{2(\mathrm{E}-z)}},$$

and

$$(36)\qquad \psi=\varpi-\chi,$$

so that ψ is given by one elliptic integral of the third kind.

But the component of angular momentum round the vertical

$$(37)\qquad \mathrm{OC}\cos\theta+\mathrm{CK}\sin\theta=\mathrm{G}'\cos\theta+\mathrm{A}\sin^2\theta\frac{d\psi}{dt}=\mathrm{G},$$

so that

$$(38)\qquad \frac{d\psi}{dt}=\frac{\mathrm{G}-\mathrm{G}'\cos\theta}{\mathrm{A}\sin^2\theta}=\frac{\mathrm{G}-\mathrm{G}'z}{\mathrm{A}(1-z^2)}$$
$$=\frac{\mathrm{G}-\mathrm{G}'}{2\mathrm{A}},\ \frac{1}{1-z}+\frac{\mathrm{G}+\mathrm{G}'}{2\mathrm{A}},\ \frac{1}{1+z},$$

which gives ψ by the sum of two elliptic integrals of the third kind; their addition into a single integral of the third kind (Legendre) being shown in (33).

The reduction of (18) to the standard form of Weierstrass is effected by putting

$$(39)\qquad \wp u-e_a=s-s_a=\tfrac{1}{2}\lambda^2(z-z_a)=\lambda^2\frac{\rho_a^2-\rho^2}{k^2},\ a=1,2,3,$$

where λ is a homogeneity factor at our disposal; and now

$$(40)\qquad nt=\int_s^{s_2}\frac{\lambda\,ds}{\sqrt{\mathrm{S}}},\ \mathrm{S}=4(s-s_1)(s-s_2)(s-s_3),$$

$$(41)\qquad \wp'^2u=\mathrm{S}=\tfrac{1}{2}\lambda^6\mathrm{Z}=\lambda^6\frac{\mathrm{R}}{k^6},$$

$$(42)\qquad u=\int_s^\infty\frac{ds}{\sqrt{\mathrm{S}}}=\int_{s_2}^\infty\frac{ds}{\sqrt{\mathrm{S}}}+\int_s^{s_2}\frac{ds}{\sqrt{\mathrm{S}}}=\omega_2+\frac{nt}{\lambda}.$$

If v, σ, Σ denote the values of u, s, S corresponding to $z=\mathrm{E}$, $\rho^2=0$,

$$(43)\qquad \wp v-\wp u=\tfrac{1}{2}\lambda^2(\mathrm{E}-z)=\lambda^2\frac{\rho^2}{k^2},$$

$$(44)\qquad i\wp'v=-\sqrt{(-\Sigma)}=\lambda^3\frac{\delta'-\mathrm{E}\delta}{k},$$

$$(45)\qquad \begin{aligned} z_1 &> \Sigma > z_2 > z > z_3,\\ \rho_1^2 &< 0 < \rho_2^2 < \rho^2 < \rho_3^2,\\ s_1 &> \sigma > s_2 > s > s_3,\end{aligned}$$

so that

$$(46)\qquad v=\omega_1+f\omega_3,\ \text{where } f \text{ is a real fraction.}$$

Then (33) becomes

$$(47)\qquad \varpi=\frac{\delta}{k}nt+\tfrac{1}{2}\int\frac{i\wp'v\,du}{\wp v-\wp u},$$

with the elliptic integral of the third kind in the standard form.

Darboux puts

$$(48)\qquad \frac{\delta}{k}=\frac{\mathrm{L}}{\lambda},\ \frac{\delta'}{k}=\frac{\mathrm{B}}{\lambda},$$

so that

$$(49)\qquad \mathrm{Z}=(\mathrm{E}-z)(1-z^2)-2\left(\frac{\mathrm{B}-\mathrm{L}z}{\lambda}\right)^2.$$

Adding equations (43)

$$(50)\qquad 3\wp v=\tfrac{1}{2}\lambda^2(3\mathrm{E}-z_1-z_2-z_3)=\lambda^2\mathrm{E}-\mathrm{L}^2.$$

$$(51)\qquad \lambda^2\mathrm{E}=\mathrm{L}^2+3\wp v,$$

$$(52)\qquad \lambda^2z=\lambda^2\mathrm{E}-2(\wp v-\wp u)=\mathrm{L}^2+\wp v+2\wp u.$$

Equation (44) becomes

$$(53)\qquad i\wp'v=\lambda^2(\mathrm{B}-\mathrm{LE})=\lambda^2\mathrm{B}-\mathrm{L}^3-3\mathrm{L}\wp v,$$

$$(54)\qquad \lambda^2\mathrm{B}=\mathrm{L}^3+3\mathrm{L}\wp v+i\wp'v.$$

Again

$$(55)\qquad \begin{aligned}2\wp''v&=\lambda^4\{3\mathrm{E}^2-2\mathrm{E}(z_1+z_2+z_3)+z_2z_3+z_3z_1+z_1z_2\}\\ &=\lambda^4\left(\mathrm{E}^2-4\mathrm{E}\frac{\mathrm{L}^2}{\lambda^2}+4\frac{\mathrm{LB}}{\lambda^2}-1\right)\\ &=\lambda^4(\mathrm{E}^2-1)+4\mathrm{L}\lambda^2(\mathrm{B}-\mathrm{LE})\\ &=\lambda^4(\mathrm{E}^2-1)+4\mathrm{L}i\wp'v;\end{aligned}$$

so that

$$(56)\qquad \begin{aligned}\lambda^4&=\lambda^4\mathrm{E}^2+4\mathrm{L}i\wp'v-2\wp''v\\ &=(\mathrm{L}^2+3\wp v)^2+4\mathrm{L}i\wp'v-2\wp''v,\end{aligned}$$

thus determining the homogeneity factor λ, when the data are L and v, and now

$$(57)\qquad \frac{\mathrm{G}}{2\sqrt{\mathrm{AM}gh}}=\frac{\delta}{k}=\frac{\mathrm{L}}{\lambda},$$

$$(58)\qquad \frac{\mathrm{G}'}{2\sqrt{\mathrm{AM}gh}}=\frac{\delta'}{k}=\frac{\mathrm{B}}{\lambda}$$
$$=\frac{\mathrm{L}^3+3\mathrm{L}\wp v+i\wp'v}{\lambda^3}.$$

The motion of the centre of a sphere, rolling and spinning in the interior of a spherical bowl, or on the top of a sphere, is found to be of the same character as the motion of the axis of a spinning top.

Suppose the top, spinning upright, receives a small tap, which imparts an angular velocity ω to the axis; then

$$(59)\qquad \delta'=\delta,\ \mathrm{E}=1+\frac{\omega^2}{2n^2},\ z_2=1;$$

and putting

$$(60)\qquad 1-z=2\sin^2\tfrac{1}{2}\theta=2x^2,$$

$$(61)\qquad \begin{aligned}2\mathrm{Z}&=16x^2\left\{\left(x^2+\frac{\omega^2}{4n^2}\right)(1-x^2)-\frac{\delta^2}{k^2}x^2\right\}\\ &=16x^2(x_1^2+x^2)(x_3^2-x^2).\end{aligned}$$

We must distinguish three cases:

I. $\qquad \delta>k.$

$$(62)\qquad \begin{aligned}x_3^2&=-\frac{1}{2}\left(\frac{\delta^2}{k^2}-1+\frac{\omega^2}{4n^2}\right)+\frac{1}{2}\sqrt{\left\{\left(\frac{\delta^2}{k^2}-1+\frac{\omega^2}{4n^2}\right)^2+\frac{\omega^2}{n^2}\right\}}\\ &\fallingdotseq\frac{\omega^2}{4n^2}\Big/\left(\frac{\delta^2}{k^2}-1\right),\end{aligned}$$

so that x_3 is proportional to ω, and the upright position of the top is stable.

Then

$$x=x_3\cos\sqrt{\left(\frac{\delta^2}{k^2}-1\right)}nt,$$

making $\frac{n}{2\pi}\sqrt{\left(\frac{\delta^2}{k^2}-1\right)}$ complete oscillations per second.

II. $\qquad \delta=k.$

$$(63)\qquad x_3^2=-\frac{\omega^2}{8n^2}+\sqrt{\left(\frac{\omega^2}{4n^2}+\frac{\omega^4}{64n^2}\right)}\fallingdotseq\frac{\omega}{2n},$$

and the upright position is still stable; and now $x=x_3\mathrm{cl}\sqrt{(\omega n)}t$.

III. $\qquad \delta<k.$

$$(64)\qquad \begin{aligned}x_3^2&=\frac{1}{2}\left(1-\frac{\delta^2}{k^2}-\frac{\omega^2}{4n^2}\right)+\frac{1}{2}\sqrt{\left\{\left(1-\frac{\delta^2}{k^2}-\frac{\omega^2}{4n^2}\right)t+\frac{\omega^2}{n^2}\right\}}\\ &\fallingdotseq 1-\frac{\delta^2}{k^2},\end{aligned}$$

so that $\theta_3=2\cos^{-1}\delta/k$, and the axis falls away to this inclination however small the tap, so that the upright position is unstable.

Ultimately

$$x=x_3\operatorname{sech}\sqrt{\left(1-\frac{\delta^2}{k^2}\right)}nt,$$

and

$$\psi=\frac{\delta}{k}nt-\cos^{-1}\frac{\frac{\delta}{k}}{\sqrt{(1-x^2)}},$$

$$\cos\tfrac{1}{2}\theta\cos\left(\frac{\delta}{k}nt-\psi\right)=\frac{\delta}{k}.$$

9. Some simple cases will elucidate the preceding theory.

Simple cases of the motion of a top.

First put

$$(1)\qquad \mathrm{G}'-\mathrm{GE}=0;$$

this makes $\wp'v=0$, and v a period, ω_1 or ω_2, $f=0$, or 1; $\mathrm{E}-z$ is now a factor of Z, z_1-z or z_2-z; and $\rho_1^2=0$, or $\rho_2^2=0$, so that

$$(2)\qquad \rho=\rho_3\mathrm{dn}(\mathrm{K}-mt),\ \text{or}\ \rho_3\mathrm{cn}(\mathrm{K}-mt),$$

while

$$(3)\qquad \varpi=\frac{\mathrm{L}}{\lambda}nt=pt,\ \text{suppose.}$$

$$(4)\qquad \chi=\varpi-\psi=pt-\psi,$$

$$(5)\qquad \tan\chi=\frac{\sqrt{\left\{1-z^2-2\frac{\mathrm{L}^2}{\lambda^2}(\mathrm{E}-z)\right\}}}{\frac{\mathrm{L}}{\lambda}\sqrt{\{2(\mathrm{E}-z)\}}};$$

and

$$(6)\qquad \sin\theta\sin(pt-\psi)=\sqrt{\{z_2-z)(z-z_3)\}},\ \text{or}\ \sqrt{\{(z_1-z)(z-z_3)\}},$$

$$(7)\qquad \sin\theta\cos(pt-\psi)=\frac{\mathrm{L}}{\lambda}\sqrt{\{2(z_1-z)\}},\quad \text{or}\ \frac{\mathrm{L}}{\lambda}\sqrt{\{2(z_2-z)\}};$$

$$(8)\qquad \frac{p}{n}=\frac{\mathrm{L}}{\lambda}=\sqrt{\frac{z_2+z_3}{2}},\ \text{or}\ \sqrt{\frac{z_1+z_3}{2}},$$

$$(9)\qquad \frac{\mathrm{B}}{\mathrm{L}}=z_1=\frac{1+z_2z_3}{z_2+z_3},\ \text{or}\ \frac{\mathrm{B}}{\mathrm{L}}=z_2=\frac{1+z_1z_3}{z_1+z_3}.$$

Next, take

$$(10)\qquad v=\omega_1+\tfrac{1}{2}\omega_3,\ f=\tfrac{1}{2},$$

and work with the corresponding pseudo-elliptic integral in the form

$$(11)\qquad \mathrm{I}=\tfrac{1}{2}\int_x^\kappa\frac{(1-\kappa)(\kappa+x^2)}{(\kappa-x^2)\sqrt{\mathrm{X}}}dx,$$

where

(12) $$X=(1-x^2)(\kappa^2-x^2),$$

(13) $$I=\sin^{-1}\sqrt{\frac{(1+x)(\kappa-x)}{2(\kappa-x^2)}}=\cos^{-1}\sqrt{\frac{(1-x)(\kappa+x)}{2(\kappa-x^2)}}.$$

To construct the corresponding herpolhode from (43) and (47) § 8, put

(14) $$\rho^2=a^2(\kappa-x^2),$$

so that, from (43) § 8,

(15) $$k^2=a^2\lambda^2,$$

(16) $$\rho_3^2-\rho^2=a^2x^2,$$

(17) $$\rho^2-\rho_2^2=a^2(\kappa^2-x^2),$$

(18) $$\rho^2-\rho_1^2=a^2(1-x^2),$$

(19) $$nt=\frac{k}{a}\int_x^\kappa\frac{dx}{\sqrt{X}},$$

(20) $$x=\kappa\,\mathrm{sn}(K-mt),\quad mt=\frac{\delta}{k}nt=\frac{nt}{M},$$

and in (47) § 8,

(21) $$\frac{\delta}{k}nt-\varpi=\int_x^\kappa\frac{\kappa(1-\kappa)dx}{(\kappa-x^2)\sqrt{X}}=I+\tfrac{1}{2}(1-\kappa)\int_x^\kappa\frac{dx}{\sqrt{X}}$$

(22) $$I=pt-\varpi,$$

where

(23) $$pt=\frac{\delta}{k}nt-\tfrac{1}{2}(1-\kappa)mt=\frac{L-\frac{1}{2}(1-\kappa)}{\lambda}nt=\{L-\tfrac{1}{2}(1-\kappa)\}mt,$$

and the herpolhode is given by

(24) $$\rho\sin(pt-\varpi)=a\sqrt{\frac{(1+x)(\kappa-x)}{2}}$$

(25) $$\rho\cos(pt-\varpi)=a\sqrt{\frac{(1-x)(\kappa+x)}{2}}.$$

This herpolhode becomes a purely algebraical curve by taking

(26) $$\delta=\tfrac{1}{2}(1-\kappa)a,\quad L=\tfrac{1}{2}(1-\kappa),$$

making $$p=0.$$

In the associated movement of the top we shall have

(27) $$\lambda^2\cos\theta=L^2-1+\kappa-\kappa^2+2x^2,$$

(28) $$\lambda^4=(L^2-1+3\kappa-\kappa^2)^2-8\kappa(1-\kappa)L+8\kappa(1-\kappa)^2,$$

(29) $$\lambda^2z_1=L^2+1+\kappa-\kappa^2,$$

(30) $$\lambda^2z_2=L^2-1+\kappa+\kappa^2,$$

(31) $$\lambda^2z_3=L^2-1+\kappa-\kappa^2,$$

(32) $$\lambda^2E=L^2-1+3\kappa-\kappa^2,$$

and operating as in (1), § 8,

(33) $$\tfrac{1}{2}\lambda^2\sin\theta\cos(pt-\psi)=(L-1+\kappa-x)\sqrt{\frac{(1-x)(\kappa+x)}{2}}$$

(34) $$\tfrac{1}{2}\lambda^2\sin\theta\sin(pt-\psi)=(L-1+\kappa+x)\sqrt{\frac{(1+x)(\kappa-x)}{2}}$$

(35) $$B=\frac{L^3-(1-3\kappa+\kappa^2)L-2\kappa(1-\kappa)}{M^2};$$

with the two constants L and κ at our disposal for the construction of numerical cases.

In the purely algebraical cases, when $p=0$, $L=\frac{1}{2}(1-\kappa)$,

(36) $$(2\lambda)^4=(1+\kappa)^2(9-14\kappa+9\kappa^2),$$

(37) $$(2\lambda)^2z_1=(1+\kappa)(5-3\kappa),$$

(38) $$(2\lambda)^2z_2=(1+\kappa)(-3+5\kappa),$$

(39) $$(2\lambda)^2z_3=-3+2\kappa-3\kappa^2,$$

(40) $$(2\lambda)^2E=-3+10\kappa-3\kappa^2,$$

(41) $$B=-\frac{3(1+\kappa)^2(1-\kappa)}{8\lambda^2}.$$

Stereoscopic figures of this case (Fig. 11) were drawn by the late Mr T. I. Dewar for

(42) $$\kappa=\frac{15}{17},\ \frac{3}{5},\ \text{and}\ \frac{1}{3}\ \text{(cusps)}.$$

Cusps occur in the general case when

(43) $$L=1\pm\sqrt{(\kappa+\kappa^2)}.$$

When $L=B=1$, the axis passes periodically through the highest vertical position; and there is an intermediate path for $L=B=-\kappa$.

The axis passes periodically through the lowest vertical position when $L=-B=1-\kappa$.

The axis moves like a spherical pendulum when $B=0$; putting $L=c(1-\kappa)$,

(44) $$\frac{1}{\kappa}+\kappa=\frac{2c^3-3c+2}{c^3-c},$$

in which c may be taken as an arbitrary parameter for the construction of numerical cases.

Other cases can be worked out for a parameter $v=\omega_1+f\omega_3$, where $f=\frac{1}{3}, \frac{1}{4}, \frac{1}{5}\ldots$; and in this way we can map out the analytical field of the most general case of motion.

10. So far the motion of the axis OCZ alone has been considered; Euler's third angle ϕ must be introduced for the specification of the motion of any point of the body.

Now if R denotes the angular velocity of the top about its axis OC,

(1) $$R=\frac{d\phi}{dt}+\cos\theta\frac{d\psi}{dt},$$

so that

(2) $$\frac{d\phi}{dt}=R-\cos\theta\frac{d\psi}{dt}=R-\frac{G\cos\theta-CR\cos^2\theta}{A\sin^2\theta}=\left(1-\frac{C}{A}\right)R+\frac{CR-G\cos\theta}{A\sin^2\theta}=\left(1-\frac{C}{A}\right)R-\frac{G-G'}{2A}\frac{1}{1-z}+\frac{G'+G}{2A}\frac{1}{1+z},$$

which gives ϕ by the difference of two elliptic integrals of the third kind; but these can be replaced by a single integral, as for ψ in (33) § 8, in the form

(3) $$\phi=\left(1-\frac{C}{A}\right)Rt+\frac{G't}{2A}-\tan^{-1}\frac{\sqrt{2AMghZ}}{G-G'z}+\frac{G-DG'}{2A}\int\frac{dt}{D-z},$$

where

(4) $$Z=(D-z)(1-z^2)-\frac{(G-G'z)^2}{2AMgh}=(D-z)(1-z^2)-2\left(\frac{\delta-\delta'z}{k}\right)^2,$$

so that

(5) $$z_1+z_2+z_3=D+\frac{G'^2}{2AMgh}=D+2\frac{\delta'^2}{k^2}=E+\frac{G^2}{2AMgh}=E+2\frac{\delta^2}{k^2}.$$

The result in (3) can be verified by differentiation; it shows that H describes in the plane CKH a herpolhode curve, and thus Jacobi's theorem is established on the allied motion of a top and two associated Poinsot movements (*Werke*, ii. p. 480).

The spherical top. It will simplify the formulas with very slight loss of generality, which can always be restored at any instant, if the *spherical* top, so called, is considered, in which C=A; this will merely cancel a secular term in ϕ, and make

(6) $$\frac{d\phi}{dt}=\frac{G'-G\cos\theta}{A\sin^2\theta},$$

equivalent to an interchange of G and G′ in ψ; and now

(7) $$\tfrac{1}{2}(\psi+\phi)=\frac{G+G'}{2A}\int\frac{dt}{1+z}=\frac{\delta+\delta'}{k}\int^{z_2}\frac{dz}{(1+z)\sqrt{2Z}},$$

(8) $$\tfrac{1}{2}(\psi-\phi)=\frac{G-G'}{2A}\int\frac{dt}{1-z}=\frac{\delta-\delta'}{k}\int^{z_2}\frac{dz}{(1-z)\sqrt{2Z}},$$

introducing two elliptic integrals of the third kind, with poles at $z=\mp1$, corresponding to parameters of the form

(9) $$v_1=f_1\omega_3,\quad v_2=\omega_1+f_2\omega_3,$$

where f_1 and f_2 are real fractions; and now, if v and w denote the parameters corresponding to $z=E$ and D, we shall find

(10) $$v=v_2-v_1,\quad w=v_2+v_1.$$

The most symmetrical treatment of the motion of any point fixed in the top will be found in Klein-Sommerfeld, *Theorie des Kreisels*, to which the reader is referred for details; four new functions, α, β, γ, δ, are introduced, defined in terms of Euler's angles, θ, ψ, ϕ, by

(11) $$\alpha=\cos\tfrac{1}{2}\theta\exp\tfrac{1}{2}(\psi+\phi)i,$$

(12) $$\beta=i\sin\tfrac{1}{2}\theta\exp\tfrac{1}{2}(\psi-\phi)i,$$

(13) $$\gamma=i\sin\tfrac{1}{2}\theta\exp\tfrac{1}{2}(-\psi+\phi)i,$$

(14) $$\delta=\cos\tfrac{1}{2}\theta\exp\tfrac{1}{2}(-\psi-\phi)i.$$

Next Klein takes two functions or co-ordinates λ and Λ, defined by

(15) $$\lambda=\frac{x+yi}{r-z}=\frac{r+z}{x-yi},$$

and Λ the same function of X, Y, Z, so that λ, Λ play the part of stereographic representations of the same point (x, y, z) or (X, Y, Z) on a sphere of radius r, with respect to poles in which the sphere is intersected by Oz and OZ.

These new functions are shown to be connected by the bilinear relation

(16) $$\lambda=\frac{\alpha\Lambda+\beta}{\gamma\Lambda+\delta},\quad \alpha\delta-\beta\gamma=1.$$

in accordance with the annexed scheme of transformation of coordinates—

	Ξ	H	Z
ξ	α^2	β^2	$2\alpha\beta$
η	γ^2	δ^2	$2\gamma\delta$
ζ	$\alpha\gamma$	$\beta\delta$	$\alpha\delta+\beta\gamma$

where

(17) $$\xi = x+yi,\ \eta = -x+yi,\ \zeta = -z,$$
$$\Xi = X+Yi,\ H = -X+Yi,\ Z = -Z;$$

and thus the motion in space of any point fixed in the body defined by Λ is determined completely by means of α, β, γ, δ; and in the case of the symmetrical top these functions are elliptic transcendants, to which Klein has given the name of *multiplicative elliptic functions;* and

(18) $$\alpha\delta = \cos^2\tfrac{1}{2}\theta,\ \beta\gamma = -\sin^2\tfrac{1}{2}\theta,$$
$$\alpha\delta-\beta\gamma = 1,\ \alpha\delta+\beta\gamma = \cos\theta,$$
$$\sqrt{(-4\alpha\beta\gamma\delta)} = \sin\theta;$$

while, for the motion of a point on the axis, putting $\Lambda=0$, or ∞,

(19) $$\lambda = \frac{\beta}{\delta} = i\tan\tfrac{1}{2}\theta e^{\psi i},\ \text{or}\ \lambda = \frac{\alpha}{\gamma} = -i\cot\tfrac{1}{2}\theta e^{\psi i},$$

and

(20) $$\alpha\beta = \tfrac{1}{2}i\sin\theta e^{\psi i},\ \alpha\gamma = \tfrac{1}{2}i\sin\theta e^{\phi i},$$

giving orthogonal projections on the planes GKH, CHK; and

(21) $$\alpha\frac{d\beta}{dt} - \frac{d\alpha}{dt}\beta = n\frac{\rho}{k}e^{\varpi i},$$

the vectorial equation in the plane GKH of the herpolhode of H for a spherical top.

When f_1 and f_2 in (9) are rational fractions, these multiplicative elliptic functions can be replaced by algebraical functions, qualified by factors which are exponential functions of the time t; a series of quasi-algebraical cases of motion can thus be constructed, which become purely algebraical when the exponential factors are cancelled by a suitable arrangement of the constants.

Gyrostat rolling in steady motion on a plane.

11. Equation (4) § 3 with slight modification will serve with the same notation for the steady rolling motion on a horizontal plane of a body of revolution, such as a disc, coin, hoop, wheel, cask, wine-glass, plate, dish, bowl, spinning top, gyrostat, or bicycle; but O is now the point of intersection of the axis GC with the vertical through the centres of the horizontal circles described by G the centre of gravity, and by P the point of contact, either with the ground, or any surface of revolution of which Oz is the vertical axis (Fig. 12).

Denoting by X, Z the horizontal and vertical components in dynes of the reaction at P,

(1) $$X = M\mu^2.GK,\ Z = Mg;$$

and taking moments round G,

(2) $$G'\mu\sin\theta - A\mu^2\sin\theta\cos\theta = N$$
$$= Z.PH + X.HG = Mg.PH + M\mu^2.GK.HG,$$

where A now denotes the moment of inertia in g-cm.² about an axis through G perpendicular to the axis of figure.

The term G′ must include not only CR, the angular momentum of the body due to the component angular velocity R above the axis GC, but also K, the total angular momentum of any fly-wheels fixed in the body with their axis parallel to GC.

Denoting KG by c, and GN, NP by z, x, the velocity of P

(3) $$= c\mu + xR - z\mu\sin\theta.$$

This is zero if P is the point of rolling contact, so that

(4) $$R = \frac{z\sin\theta - c}{x}\mu,$$

and therefore

(5) $$K\mu\sin\theta + C^2\frac{\sin\theta - c}{x}\mu^2\sin\theta$$
$$-A\mu^2\sin\theta\cos\theta - Mc(z\cos\theta + x\sin\theta)\mu^2$$
$$-Mg(z\sin\theta - x\cos\theta) = 0.$$

Gyrostat swung round by a thread.

But if the gyrostatic body is swinging round in relative equilibrium at the end of a thread O′P of length l inclined at an angle α to the vertical attached to the point P,

(6) $$X = Mg\tan\alpha = Mc\mu^2$$
$$= M(l\sin\alpha + z\sin\theta - x\cos\theta);$$

and the axis of resultant angular velocity being vertical, $R=\mu\cos\theta$, so that

(7) $$K\mu\sin\theta + (C-A)\mu^2\sin\theta\cos\theta = N$$
$$= T.GL = Mg\sec\alpha.GL,$$

where GL is the perpendicular from G on the thread.

Stability of a rotating projectile.

When a solid of revolution is moving in unlimited frictionless liquid with axial velocity V and sidelong velocity U, it experiences a deflecting couple

(8) $$N = (c_1 - c_3)UV,$$

in accordance with the principles of hydrodynamics, $c_3V = F\cos\theta$, and $c_1U = F\sin\theta$, being the components of the impulse F required to give the body its actual motion; so that equation (2) becomes

(9) $$G'\mu\sin\theta - A\mu^2\sin\theta\cos\theta = \frac{c_3}{c_1}(c_1-c_3)V^2\tan\theta.$$

Dividing out sin θ, which equated to zero would give perfectly centred axial motion, the quadratic in μ becomes

(10) $$A\mu^2\cos\theta - G'\mu + \frac{c_3}{c_1}(c_1-c_3)V^2\sec\theta = 0,$$

so that the least admissible value of $G'=CR$ for steady motion is given by

(11) $$\frac{R^2}{V^2} = 4\frac{A}{C^2}\frac{c_3}{c_1}(c_1-c_3).$$

Suppose the solid is an elongated projectile, fired through the air by a d cm. gun, in which the final angle of the rifling at the muzzle is β; then

(12) $$\tan\beta = \frac{\tfrac{1}{2}dR}{V}.$$

We can put

(13) $$c_1 = M + M'\alpha,\ c_3 = M + M'\gamma,\ c_1 - c_3 = M'(\alpha-\gamma),$$

where M, M′ denote the weight in grams of the body and of the displaced air or fluid, and α, γ are functions of the shape of the body; also

(14) $$C = Mk_3^2,\ A = Mk_1^2 + M'k_1'^2.$$

Now in air, the fraction M′/M is so small that the first power only need be retained, and

(15) $$\tan^2\beta = \frac{d^2k_1^2}{k_3^4}(\alpha-\gamma)\frac{M'}{M},$$

which determines β the angle of rifling suitable for stability in flight of a projectile for which α and γ are known.

Stability of an automobile torpedo.

But if the body is like an automobile torpedo, submerged in water with zero buoyancy, then M′=M, and the exact expression must be used

(16) $$\frac{G'^2}{V^2} = 4(Mk_1^2 + M'k_1'^2)\frac{1+\gamma}{1+\alpha}(\alpha-\gamma)M.$$

The term G′ is supplied in the Whitehead torpedo by the action of a fly-wheel in the interior.

General motion of a gyrostat rolling on a plane.

12. In the theoretical discussion of the general motion of a gyrostat rolling on a horizontal plane, apparently the simplest plan is to write down the most general equations of motion, and afterwards to introduce the special conditions.

Drawing through G the centre of gravity any three rectangular axes Gx, Gy, Gz, the notation employed is

u, v, w, the component linear velocities of G,
p, q, r, the component angular velocities above the axes,
h_1, h_2, h_3, the components of angular momentum,
θ_1, θ_2, θ_3, the component angular velocities of the system of rectangular axes,
x, y, z, the co-ordinates of the point of contact with the horizontal plane,
X, Y, Z, the components of the reaction of the plane,
α, β, γ, the direction cosines of the downward vertical.

The dynamical equations are

(1) $$\frac{du}{dt} - v\theta_3 + w\theta_2 = g\alpha + \frac{X}{M},$$

(2) $$\frac{dv}{dt} - w\theta_1 + u\theta_3 = g\beta + \frac{Y}{M},$$

(3) $$\frac{dw}{dt} - u\theta_2 + v\theta_1 = g\gamma + \frac{Z}{M},$$

and

(4) $$\frac{dh_1}{dt} - h_2\theta_3 + h_3\theta_2 = yZ - zY,$$

(5) $$\frac{dh_2}{dt} - h_3\theta_1 + h_1\theta_3 = zX - xZ,$$

(6) $$\frac{dh_3}{dt} - h_1\theta_2 + h_2\theta_1 = xY - yX.$$

The geometrical equations, expressing that the point of contact has no velocity, are

(7) $$u - yr + zq = 0,$$
(8) $$v - zp + xr = 0,$$
(9) $$w - xq + yp = 0.$$

In the special case of the gyrostat, where the surface is of revolution about Gz, and the body is kinetically symmetrical about Gz, we take Gy horizontal and Gzx through the point of contact, so that $y=0$; and denoting the angle between Gz and the downward vertical by θ (Fig. 12),

(10) $$\alpha=\sin\theta,\ \beta=0,\ \gamma=\cos\theta;$$

while denoting the angular velocity of the plane Gzx about the vertical by Ω,

(11) $$\theta_1=\Omega\sin\theta,\ \theta_2=-\frac{d\theta}{dt},\ \theta_3=\Omega\cos\theta.$$

The components of angular momentum are given by

(12) $$h_1=\mathrm{A}p,\ h_2=\mathrm{A}q,\ h_3=\mathrm{C}r+\mathrm{K},$$

where K is the angular momentum of interior fly-wheels whose axes are fixed parallel to Gz; and as Gz is fixed in the body

(13) $$p=\theta_1=\Omega\sin\theta,\ q=\theta_2=-\frac{d\theta}{dt}.$$

The elimination of the reactions leads to the general equations of motion, of which one integral can be written down from the principle of energy.

We shall confine ourselves to the special case in which x and z are constant, so that the body has a plane circular base, like a disc, a wine-glass, or Kelvin's gyrostat (Fig. 4).

Now, from (1), (6), with $y=0$,

(14) $$\frac{\mathrm{X}}{\mathrm{M}}=z\frac{d^2\theta}{dt^2}-(z\Omega\sin\theta-xr)\Omega\cos\theta+x\frac{d\theta^2}{dt^2}-g\sin\theta$$

(15) $$\frac{\mathrm{Y}}{\mathrm{M}}=z\frac{d\Omega\sin\theta}{dt}-x\frac{dr}{dt}+(x\sin\theta+z\cos\theta)\Omega\frac{d\theta}{dt}$$

(16) $$\frac{\mathrm{Z}}{\mathrm{M}}=-x\frac{d^2\theta}{dt}+z\frac{d\theta^2}{dt^2}+(z\Omega\sin\theta-xr)\Omega\sin\theta-g\cos\theta$$

(17) $$-z\mathrm{Y}=\mathrm{A}\frac{d\Omega\sin\theta}{dt}+\mathrm{A}\frac{d\theta}{dt}\Omega\cos\theta-(\mathrm{C}r+\mathrm{K})\frac{d\theta}{dt}$$

(18) $$z\mathrm{X}-x\mathrm{Z}=-\mathrm{A}\frac{d^2\theta}{dt}-(\mathrm{C}r+\mathrm{K})\Omega\sin\theta+\mathrm{A}\Omega^2\sin\theta\cos\theta$$

(19) $$x\mathrm{Y}=\mathrm{C}\frac{dr}{dt},\ \text{treating K as constant.}$$

The elimination of Y between (15) and (19) leads to

(20) $$x\mathrm{Y}=\mathrm{C}\frac{dr}{dt}$$
$$=\mathrm{M}xz\frac{d\Omega\sin\theta}{dt}-\mathrm{M}x^2\frac{dr}{dt}+\mathrm{M}x(x\sin\theta+z\cos\theta)\frac{\Omega d\theta}{dt}$$

(21) $$(\mathrm{C}+\mathrm{M}x^2)\frac{dr}{d\theta}-\mathrm{M}xz\frac{d\Omega\sin\theta}{d\theta}-\mathrm{M}(x^2\sin\theta+xz\cos\theta)\Omega=0;$$

or putting $\Omega\sin^2\theta=\mathrm{N}$, and $\mathrm{C}r+\mathrm{K}=\mathrm{G}'$,

(22) $$(\mathrm{C}+\mathrm{M}x^2)\sin\theta\frac{d\mathrm{G}'}{d\theta}-\mathrm{CM}xz\frac{d\mathrm{N}}{d\theta}-\mathrm{CM}x^2\mathrm{N}=0.$$

Between (15) and (17) the elimination of Y leads to

(23) $$(\mathrm{A}+\mathrm{M}z^2)\frac{d\mathrm{N}}{d\theta}+\mathrm{M}xz\mathrm{N}$$
$$-\mathrm{M}xz\sin\theta\frac{dr}{d\theta}-(\mathrm{C}r+\mathrm{K})\sin\theta=0;$$

so that from (22) and (23) putting $(\mathrm{A}+\mathrm{M}z^2)(\mathrm{C}+\mathrm{M}x^2)-\mathrm{M}^2x^2z^2=\mathrm{D}$,

(24) $$\mathrm{A}x\frac{d\mathrm{N}}{d\theta}=\left(-z\frac{d\mathrm{G}'}{d\theta}+x\mathrm{G}'\right)\sin\theta,$$

(25) $$\mathrm{ACM}x^2\mathrm{N}=\left(\mathrm{D}\frac{d\mathrm{G}'}{d\theta}-\mathrm{CM}xz\mathrm{G}'\right)\sin\theta;$$

or

(26) $$(\mathrm{C}+\mathrm{M}x^2)\frac{d\mathrm{G}'}{d\theta}\sin\theta=\mathrm{CM}xz\frac{d\mathrm{N}}{d\theta}+\mathrm{CM}x^2\mathrm{N},$$

(27) $$(\mathrm{C}+\mathrm{M}x^2)\mathrm{G}'\sin\theta=\mathrm{D}\frac{d\mathrm{N}}{d\theta}+\mathrm{CM}xz\mathrm{N}.$$

With $z=0$, as in a disc or Kelvin's gyrostat

(28) $$\mathrm{A}\frac{d\mathrm{N}}{d\theta}=\mathrm{G}'\sin\theta,\ \mathrm{CM}x^2\mathrm{N}=(\mathrm{C}+\mathrm{M}z^2)\frac{d\mathrm{G}'}{d\theta}\sin\theta;$$

leading to the differential equations of a hypergeometric series for G′ and N,

(29) $$\frac{d^2\mathrm{G}'}{d\theta^2}+\cot\theta\frac{d\mathrm{G}'}{d\theta}-\frac{\mathrm{CM}x^2}{\mathrm{A}(\mathrm{C}+\mathrm{M}x^2)}\mathrm{G}'=0,$$

(30) $$\frac{d^2\mathrm{N}}{d\theta^2}-\cot\theta\frac{d\mathrm{N}}{d\theta}-\frac{\mathrm{CM}x^2}{\mathrm{A}(\mathrm{C}+\mathrm{M}x^2)}\mathrm{N}=0;$$

of the form of Legendre's equation for a zonal harmonic of fractional order n, given by

(31) $$n(n+1)=\frac{\mathrm{CM}x^2}{\mathrm{A}(\mathrm{C}+\mathrm{M}x^2)}$$

(Appell and Korteweg, *Circolo matematico di Palermo*, Aug. 1899).

But in the general case, when z is not zero, the differential equations become

(32) $$\frac{d^2\mathrm{G}'}{d\theta^2}+\cot\theta\frac{d\mathrm{G}'}{d\theta}-\frac{\mathrm{CM}(x^2+xz\cot\theta)}{\mathrm{D}}\mathrm{G}'=0,$$

(33) $$\frac{d^2\mathrm{N}}{d\theta^2}-\cot\theta\frac{d\mathrm{N}}{d\theta}-\frac{\mathrm{CM}(x^2+xz\cot\theta)}{\mathrm{D}}\mathrm{N}=0.$$

The elimination of X and Z between equations (14), (16), (18), leads to

(34) $$\{\mathrm{A}+\mathrm{M}(x^2+z^2)\}\frac{d^2\theta}{dt^2}-(\mathrm{A}+\mathrm{M}z^2)\Omega^2\sin\theta\cos\theta$$
$$-\mathrm{M}xz\Omega^2\sin^2\theta+\{(\mathrm{C}+\mathrm{M}x^2)r+\mathrm{K}\}\Omega\sin\theta$$
$$+\mathrm{M}xzr\Omega\cos\theta+\mathrm{M}g(x\cos\theta-z\sin\theta)=0;$$

and this, in conjunction with (20) and (23) will lead to an equation, the integral of which is the equation of Energy, which can be written down in the form

(35) $$\tfrac{1}{2}\mathrm{M}(u^2+v^2+w^2)+\tfrac{1}{2}\mathrm{A}(p^2+q^2)$$
$$+\tfrac{1}{2}\mathrm{C}r^2+\mathrm{M}g(x\sin\theta+z\cos\theta)=\mathrm{H},$$

a constant; or

(36) $$\tfrac{1}{2}\{\mathrm{A}+\mathrm{M}(x^2+z^2)\}\left(\frac{d\theta}{dt}\right)^2$$
$$+\tfrac{1}{2}(\mathrm{A}+\mathrm{M}z^2)\Omega^2\sin^2\theta$$
$$-\mathrm{M}xzr\Omega\sin\theta$$
$$+\tfrac{1}{2}(\mathrm{C}+\mathrm{M}x^2)r^2$$
$$+\mathrm{M}g(x\sin\theta+z\cos\theta)=\mathrm{H}.$$

Put $x=0$ and we fall back on the original equations for a top spinning with its point in a small smooth fixed cup, like the Maxwell top.

13. To find the small oscillations about a state of steady motion where the axis has a mean inclination α to the vertical, put

(1) $$\theta=\alpha+\mathrm{P}e^{\lambda ti},\ \sin\theta=\sin\alpha(1+\mathrm{P}e^{\lambda ti}\cot\alpha),$$
$$\cos\theta=\cos(\alpha 1-\mathrm{P}e^{\lambda ti}\tan\alpha)$$
$$\mathrm{N}=\mathrm{H}+\mathrm{Q}e^{\lambda ti},\ \mathrm{G}'=\mathrm{L}+\mathrm{R}e^{\lambda ti},$$

where P, Q, R are small, and

(2) $$\frac{d\mathrm{N}}{d\theta}=\frac{\mathrm{Q}}{\mathrm{P}},\ \frac{d\mathrm{G}'}{d\theta}=\frac{\mathrm{R}}{\mathrm{P}},$$

to the order considered.

A substitution in (34) § 12 will lead to the condition of steady motion, and a relation between P, Q, R, which in conjunction with equations (24) to (27) will lead on elimination of P, Q, R to the equation which determines λ^2; and if λ^2 is positive the motion is stable (Routh, *Rigid Dynamics*, ii., § 241).

Take the case where the gyrostat is performing small nutations about a position of steady motion when the gyrostat proceeds with its axis horizontal in a straight course with velocity V.

Then in (1), with

(3) $$z=0,\ \alpha=\tfrac{1}{2}\pi,\ \sin\theta=1,\ \cos\theta=-\mathrm{P}e^{\lambda ti},$$

and

$$\mathrm{H}=0,\ \mathrm{L}=\frac{\mathrm{V}}{x}+\mathrm{K},$$

we shall find $\mathrm{R}=0$, and

(4) $$\frac{\mathrm{Q}}{\mathrm{P}}=\frac{\mathrm{C}\frac{\mathrm{V}}{x}+\mathrm{K}}{\mathrm{A}}=\frac{(\mathrm{A}+\mathrm{M}x^2)\lambda^2+\mathrm{M}gx}{(\mathrm{C}+\mathrm{M}x^2)\frac{\mathrm{V}}{x}+\mathrm{K}};$$

(5) $$\mathrm{A}(\mathrm{A}+\mathrm{M}x^2)\lambda^2=\left\{(\mathrm{C}+\mathrm{M}x^2)\frac{\mathrm{V}}{x}+\mathrm{K}\right\}\left(\mathrm{C}\frac{\mathrm{V}}{x}+\mathrm{K}\right)-\mathrm{AM}gx,$$

and λ^2 must be positive for the motion to be stable.

Thus, putting $\mathrm{V}=0$, so that

(6) $$\mathrm{A}(\mathrm{A}+\mathrm{M}x^2)\lambda^2=\mathrm{K}^2-\mathrm{AM}gx,$$

it is possible for the gyrostat to maintain itself upright on its edge without advance, as in Fig. 6, provided

(7) $$\mathrm{K}^2-\mathrm{AM}gx \text{ is positive.}$$

In a solid rolling disc, or coin, or symmetrical body rolling on its edge,

(8) $$\mathrm{K}=0,\ \mathrm{A}(\mathrm{A}+\mathrm{M}x^2)\lambda^2=\mathrm{C}(\mathrm{C}+\mathrm{M}x^2)\frac{v^2}{x^2}-\mathrm{AM}gx,$$

and the right-hand side must be positive for the straight advance to be stable.

For further theory and experiments consult Routh, *Advanced Rigid Dynamics*, chap. v., and Thomson and Tait, *Natural Philosophy*, § 345; also Bourlet, *Traité des bicycles* (analysed in Appell, *Mécanique rationelle*, ii. p. 297, and Carvallo, *Journal de l'école polytechnique*, 1900); Whipple, *Quarterly Journal of Mathematics*, vol. xxx., for mathematical theories of the bicycle.

In some experiments, described by Lord Kelvin in *Nature*, February 1877 and November 1880, the fly-wheel of the gyrostat is replaced by a spheroid of thin copper, filled with water; if spun rapidly the motion is stable if the spheroid is oblate, but becomes highly unstable for the prolate form, as exemplified by the difficulty

of spinning a raw egg; but the motion should become stable again when the egg-shaped spheroid is elongated to more than three diameters long (*Proc. Cam. Phil. Soc.*, 1882).

If the fly-wheel is fixed symmetrically at the centre of a spherical case which can roll on a horizontal plane, the preceding results can be modified so as to lead to analytical equations comparable in some cases with Kirchhoff's equations for the motion of a solid in unlimited liquid.

14. Lord Kelvin has also studied, theoretically and experimentally, the vibration of a chain of stretched gyrostats (*Proc. London Math. Society*, 1875; Perry, *Spinning Tops*, p. 127, for a diagram).

Supposing the gyrostats, each of axial length $2a$, connected by light cords each of length $2l$, stretched to a tension T, and supposing x, y denote the component slight displacements from the central straight line of the centre of a gyrostat, and that p, q, 1 denote the direction cosines of the axis of gyrostat, and r, s, 1 the direction cosines of a cord, distinguishing the different bodies by suffixes; then, as in Routh's *Advanced Rigid Dynamics*, p. 266, neglecting the squares of small quantities, we can put

(1) $$\theta_1 = -\frac{dq}{dt},\ \theta_2 = \frac{dp}{dt},\ \theta_3 = r;$$

(2) $$h_1 = A\theta_1,\ h_2 = A\theta_2,\ h_3 = K;$$

in the dynamical equations

(3) $$\frac{dh_1}{dt} - h_2\theta_3 + h_3\theta_2 = L, \ \ldots$$

so that for the k^{th} gyrostat, these equations reduce to

(4) $$A\ddot{q}_k - K\dot{p}_k = Ta(s_k + s_{k+1} - 2q_k),$$

(5) $$A\ddot{p}_k + K\dot{q}_k = Ta(r_k + r_{k+1} - 2p_k).$$

Also, for the motion of translation

(6) $$M\ddot{x}_k = T(r_{k+1} - r_k),\ M\ddot{y}_k = T(s_{k+1} - s_k).$$

The geometrical relations are

(7) $$x_{k+1} - x_k = a(p_{k+1} + p_k) + 2lr_{k+1}$$
$$y_{k+1} - y_k = a(q_{k+1} + q_k) + 2ls_{k+1}.$$

Putting

(8) $$x + yi = w,\ p + qi = \varpi,\ r + si = \sigma,$$

these three pairs of equations can be written

(9) $$A\ddot{\varpi}_k - K\dot{\varpi}_k i + 2Ta\varpi_k - Ta(\sigma_{k+1} + \sigma_k) = 0,$$

(10) $$M\ddot{w}_k - T(\sigma_{k+1} - \sigma_k) = 0,$$

(11) $$w_{k+1} - w_k - a(\varpi_{k+1} + \varpi_k) - 2l\sigma_{k+1} = 0.$$

For circularly polarized vibrations assume a solution

(12) $$w_k,\ \varpi_k,\ \sigma_k = (L,\ P,\ Q)\exp(nt - ck)i,$$

so that n/c is the velocity of propagation: then

(13) $$P(-An^2 + Kn + 2Ta) - QTa(e^{-ci} + 1) = 0,$$

(14) $$-LMn^2 - QT(e^{-ci} - 1) = 0,$$

(15) $$L(e^{-ci} - 1) - Pa(e^{-ci} + 1) - 2Qle^{-ci} = 0;$$

leading on elimination of L, P, Q, to

(16) $$\cos c = \frac{(-An^2 + Kn + 2Ta)\left(1 - \frac{Mln^2}{T}\right) - Ma^2n^2}{-An^2 + Kn + 2Ta + Ma^2n^2}$$

(17) $$2\sin^2 \tfrac{1}{2}c = Mn^2\frac{(-An^2 + Kn + 2Ta)\frac{l}{T} + 2a^2}{-An^2 + Kn + 2Ta + Ma^2n^2}.$$

Put

(18) $$M = 2(a + l)\rho,\ K = 2(a + l)\kappa,$$
$$z = 2(a + l)k,$$
$$ck = ez,$$

so that
$$c = 2(a + l)e;$$

then

(19) $$\sin^2(a + l)e = \rho(a + l^2)n^2\frac{1 + \frac{\kappa ln}{Ta} - 2\frac{Aln^2}{Ta(a + l)}}{T + \kappa n\frac{a + l}{a} - \frac{An^2}{a} + 2\rho a(a + l)n^2}.$$

With $a + l$ infinitesimal, and neglecting the rotary inertia a,

(20) $$\frac{n^2}{e^2} = \frac{T}{\rho}\,\frac{1 + \frac{a + l}{a}\,\frac{\kappa n}{T}}{1 + \frac{l}{a}\,\frac{\kappa n}{T}} \approx \frac{T}{\rho}\left(1 + \frac{\kappa n}{T}\right).$$

This agrees with the result obtained by Larmor (*Proc. London Math. Society*, 1890) for the propagation of vibrations along a cord provided with a continuous distribution of gyrostatic momentum; the differential equation of vibration is of the form

(21) $$\frac{d^2w}{dt^2} = \frac{T}{\rho}\,\frac{d^2w}{dz^2} - ih\frac{d^3w}{dz^2dt},$$

so that, for the circularly polarized vibrations

(22) $$w = L\exp(nt - ez)i$$

(23) $$n^2 = \frac{T}{\rho}e^2 + hne^2,\ \frac{n}{e} = \sqrt{\left(\frac{T}{\rho} + hn\right)}.$$

For circular polarization in the opposite direction

(24) $$w' = x - yi = L'\exp(nt - e'x)i,$$

and now the velocity of propagation

(25) $$\frac{n}{e'} = \sqrt{\left(\frac{T}{\rho} - hn\right)}.$$

In this way a mechanical analogue is obtained of the action of a magnetized medium on polarized light (Larmor, *Aether and Matter*, Appendix E).

Gyrostat suspended by a thread.

15. In the discussion of the small vibration of a single gyrostat about the vertical position, when suspended by a single thread of length $2l = b$, we can dispense with the suffix k in the preceding equations (9), (10), (11), § 14, and write

(1) $$A\ddot{\varpi} - K\dot{\varpi}i + Ta\varpi - Ta\sigma = 0,$$

(2) $$M\ddot{w} + T\sigma = 0,\ \text{with } T = Mg,$$

(3) $$w - a\varpi - b\sigma = 0.$$

Putting

(4) $$w,\ \varpi,\ \sigma = (L,\ P,\ Q)\exp nti$$

in these equations, and eliminating L, P, Q,

(5) $$(-An^2 + Kn + Mga)(g - bn^2) - Mga^2n^2 = 0,$$

and the period of a fundamental vibration is $2\pi/n$, where n is a root of this quartic equation (5).

For a gyrostat, spinning upright on its point on a smooth horizontal plane, put $b = \infty$, and change the sign of a; then

(6) $$An^2 - Kn + Mga = 0,$$

so that the condition

(7) $$K^2 > 4AMga$$

is required for stability.

Here A denotes the moment of inertia about an axis through the centre of gravity; in the same condition required for stability when the point is held in a small smooth cup ($b = 0$), A must be taken to represent the moment of inertia about a parallel axis through the point.

Spinning upright inside a smooth spherical surface of radius b, the sign of a must be changed to obtain the conditions at the lowest point.

For a gyrostat spinning upright on the summit of a smooth sphere of radius b, the sign of a and b must be changed, or else the sign of g, which amounts to the same thing.

Denoting the component horizontal displacements of the point by ξ, η, then

(8) $$br = \xi,\ bs = \eta,\ b\sigma = \xi + \eta i = \zeta, \text{ suppose}$$

(9) $$w = a\varpi + \zeta.$$

Now if the point is forced to take the motion (ξ, η, 0) by component forces X, Y, Z, the equations of motion of the gyrostat become

(10) $$-A\ddot{q} + K\dot{p} = -Zaq + Ya,$$

(11) $$+A\ddot{p} + K\dot{q} = +Zap - Xa,$$

(12) $$X + Yi = M\ddot{w},\ Z = -Mg;$$

so that

(13) $$A\ddot{\varpi} - K\dot{\varpi}i + Mga\varpi + Ma\ddot{w} = 0$$

or

(14) $$(A + Ma^2)\ddot{\varpi} - K\dot{\varpi}i + Mga\varpi + Ma\ddot{\zeta} = 0.$$

Thus if the point of the gyrostat is made to take the motion given by $\zeta = R\exp(nti)$, the forced vibration of the axis is given by $\varpi = P\exp(nti)$, where

(15) $$P\{-(A + Ma^2)n^2 + Kn + Mga\} - RMan^2 = 0.$$

The flexure joint.

In Lord Kelvin's experiments the gyrostats are joined up by equal light rods and short lengths of elastic wire, with rigid attachment to the rod and the case of a gyrostat, so as to keep the system still, and free from entanglement and twisting due to pivot-friction of fly-wheels.

When this gyrostatic chain is made to rotate with angular velocity n in relative equilibrium as a plane polygon passing through Oz, each gyrostatic case moves as if its axis produced was attached to Oz by a flexure joint, so that its instantaneous axis of resultant angular velocity bisects the angle $\pi - \theta$, if the axis makes an angle θ with Oz; and the components of angular velocity about Oz being n and about the axis being $-n$, the resultant angular velocity is $2n\cos\frac{1}{2}(\pi - \theta) = 2n\sin\frac{1}{2}\theta$, and the components of this angular velocity are

(16) $-2n\sin\frac{1}{2}\theta\sin\frac{1}{2}\theta = -n(1 - \cos\theta)$, along the axis

(17) $-2n\sin\frac{1}{2}\theta\cos\frac{1}{2}\theta = -n\sin\theta$, perpendicular to the axis of the gyrostat.

The component angular momentum in the direction Ox is therefore

(18) $$L = -An\sin\theta\cos\theta - Cn(1 - \cos\theta)\sin\theta + K\sin\theta,$$

and Ln is therefore the couple acting on the gyrostat.

If ϕ denotes the angle which a rod makes with Oz, and T denotes the constant component of the tension of a rod parallel to Oz, the couple acting is

(19) $$Ta \cos \theta_k (\tan \phi_{k+1} + \tan \phi_k) - 2Ta \sin \theta_k,$$

which is to be equation to Ln, so that

(20) $$-An^2 \sin \theta_k \cos \theta_k - Cn(1-\cos \theta_k) \sin \theta_k + Kn \sin \theta_k + 2Ta \sin \theta_k - Ta \cos \theta_k (\tan \phi_{k+1} + \tan \phi_k) = 0.$$

In addition

(21) $$Mn^2 x_k + T(\tan \phi_{k+1} - \tan \phi_k) = 0,$$

with the geometrical relation

(22) $$x_{k+1} - x_k - a(\sin \theta_{k+1} + \sin \theta_k) - 2L \sin \phi_{k+1} = 0.$$

When the polygon is nearly coincident with Oz, these equations can be replaced by

(23) $$(-An^2 + Kn + 2Ta)\theta_k - Ta(\phi_{k+1} + \phi_k) = 0,$$

(24) $$Mn^2 x_k + T(\phi_{k+1} - \phi_k) = 0,$$

(25) $$x_{k+1} - x_k - a(\theta_{k+1} + \theta_k) - 2L\phi_k = 0;$$

and the rest of the solution proceeds exactly as before, in § 14.

Gyroscopic pendulum. The elastic flexure joint is useful for supporting the gyroscopic pendulum, consisting of a rod and a gyroscope on its axis.

Expressed by Euler's angles the kinetic energy

(26) $$T = \tfrac{1}{2}A(\dot\theta^2 + \sin^2 \theta \dot\psi^2) + \tfrac{1}{2}C(1-\cos \theta)^2 \dot\psi^2 + \tfrac{1}{2}C'(\dot\phi + \dot\psi \cos \theta)^2,$$

where A refers to rod and gyroscope, C to rod and case, and C′ to revolving fly-wheel; and applying Lagrange's equations, the time is given as a function of $\cos \theta$ by a *hyperelliptic* integral.

A diagram is given in Perry's *Spinning Tops*, p. 126; but if the support is a smooth ball-and-socket joint, the motion is given by elliptic functions, as developed previously.

Authorities.—For a complete list of the mathematical works on the subject of the Gyroscope and Gyrostat from the outset, Professor Cayley's Report to the British Association, 1862, on the *Progress of Dynamics* should be consulted. Modern authors will be found cited in Klein-Sommerfeld, *Theorie des Kreisels*, 1897.

(A. G. G.)

Gyula-Fehérvár (German, *Karlsburg*), a corporate town of Hungary, in the county of Alsó-Fehér. It is the seat of the Transylvanian Roman Catholic bishop, and contains a royal tribunal, a chamber of advocates, several schools and important financial institutions, a museum, &c. Its origin dates from the Roman period. In the 16th century, when Transylvania separated from Hungary, it was the residence of the Transylvanian princes, but after that time it decayed. The fortress was constructed by order of Charles III. between 1715 and 1735; hence the German name of the town. Population (1891), 8167; (1900), 11,507.

Haarlem, capital of the province of North Holland (Netherlands), 11 miles west of Amsterdam by rail, at the foot of the dunes and near the confluence of the Spaarne and the Y. Profiting by the advantages of its situation, the town uses the dune water for bleaching and brewing purposes, and the fertile Kennemerland for agriculture. The industrial rise of Leyden, Brabant, Flanders, and the commercial rise of Amsterdam, have lessened the importance of Haarlem, but it is still a considerable market for agricultural produce (butter and cheese) and cattle, and has a flourishing trade in "Dutch bulbs." More recent industries are the manufacture of tram and railway carriages and machinery, type-founding, bank-note and stamp printing, &c. Here, too, are the works of the Dutch railway. A steam tramway was opened in 1898, and the Colonial museum has been added to that of industrial art, both founded by the Society for Promoting Industry. Population (1900), 64,069.

Hackensack, capital of Bergen county, New Jersey, U.S.A., in 40° 53′ N. lat. and 74° 03′ W. long., on the W. bank of the river Hackensack. Its site is level, and it has a regular plan. It is on four railways—the New Jersey and New York; the New York, Ontario, and Western; the New York, Susquehanna, and Western; and the West Shore. Population (1880), 4248; (1890), 6004; (1900), 9443, of whom 2009 were foreign-born and 515 were negroes.

Haddington, or East Lothian, a maritime county of Scotland, bounded on the N. by the Firth of Forth, on the E. by the North Sea, on the S. by Berwickshire, and on the W. by Edinburghshire.

Area and Population.—In 1891 the boundary between Haddington and Midlothian was altered in the parishes of Humbie and Fala and Soutra, the whole of the former and part of the latter being transferred to Midlothian, and between Haddington and Berwickshire in the parish of Oldhamstocks, which, deprived of its Berwick portion, was placed wholly in Haddington. According to the latest official estimate, the area of the county (foreshore excluded) is 171,377 acres, or 267·7 square miles. The population was in 1881, 38,502; in 1891, 37,485; in 1891 on the above area, 37,377, of whom 18,169 were males and 19,208 females; in 1901, 38,662. On the old area, land only (271 square miles), the number of persons to the square mile in 1891 was 138, and the number of acres to the person, 4·6. In the registration county the decrease of population between 1881 and 1891 was 2·55 per cent. Between 1881 and 1891 the excess of births over deaths was 5001, and the decrease of the resident population was 980. The following table gives particulars of births, deaths, and marriages in 1880, 1890, and 1899:—

Year.	Deaths.	Marriages.	Births.	Percentage of Illegitimate.
1880	627	175	1166	6·1
1890	623	194	968	7·23
1899	567	205	955	6·0

The following table gives the birth-rate, death-rate, and marriage-rate per thousand of the population for a series of years:—

	1880.	1881-90.	1890.	1891-98	1899.
Birth-rate . .	30·32	29·15	25·75	27·02	26·19
Death-rate . .	16·31	15·95	16·57	16·38	15·55
Marriage-rate .	4·55	5·39	5·16	5·79	5·62

In 1891 there were 515 Gaelic-speaking persons in the county, and 70 foreigners. Valuation in 1889–90, £278,715; 1899–1900, £278,783.

Constitution and Government.—The county returns one member to Parliament. The principal towns are Haddington (3992), North Berwick (2784), Dunbar (3581), Tranent (2584), and Prestonpans (1721). There are 24 civil parishes, forming two combinations with Berwick and Midlothian parishes, with poorhouse at Prestonkirk and Inveresk; the number of paupers and dependants in September 1899 was 958. Haddingtonshire forms part of the sheriffdom of the Lothians and Peebles, and there is a resident sheriff-substitute at Haddington, who sits also at Dunbar, Tranent, and North Berwick.

Education.—Twenty-six school boards manage 41 schools, which had an average attendance of 5062 in 1898–99, while three voluntary schools had 187. There are high schools at North Berwick and Haddington, and seven other schools earned grants in 1898–99 for giving higher education. The County Council spends a proportion of the "Residue" grant in supporting short courses of instruction in technical subjects, chiefly agriculture, in experiments in feeding cattle and growing crops, and in paying the travelling expenses of technical students.

Agriculture.—Though it no longer stands high above the other counties in the kingdom in respect of successful farming on a large scale, East Lothian is still famous for the richness of its corn and root crops, the size of its holdings, and the good housing of its farm labourers. In 1895 the average size of the 558 holdings was 201 acres; 14·70 per cent. were under 5 acres, 24·55 were between 5 and 50, and 60·75 were over 50 acres. The number between 50 and 100 acres was 36; between 100 and 300, 129; between 300 and 500, 120; between 500 and 1000, 52, and there were two over 1000. In 1898 the percentage of cultivated area was 65·3, a figure exceeded only by Fife and Linlithgow. Among the grain crops oats are almost a constant. Wheat is reviving after a steady and prolonged fall in acreage, while barley has varied remarkably little during the decade ending 1899. The

following table gives the principal acreages at intervals of ten years from 1880:—

Year.	Area under Crops.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	115,804	45,299	26,163	27,088	16,242	1012
1890	115,691	40,506	24,036	30,175	20,296	276
1899	111,902	39,463	24,624	27,539	19,852	44

The following table gives particulars of the live stock at intervals of five years from 1880:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or Calf.	Sheep.	Pigs.
1880	3753	8,237	1807	111,886	2490
1885	3467	11,327	1864	132,447	2583
1890	3620	12,379	1832	142,070	2220
1895	3788	9,506	1808	127,483	2138
1899	3555	10,115	2011	131,221	2171

The acreage under wood in 1895 was 10,472. In 1891, 4132 men and 1654 women were returned as being engaged in agriculture.

Industries and Trade.—The coalfield in Haddington West is 30 square miles in extent, with ten seams. In 1890, 300,159 tons of coal, valued at £101,304, were raised; in 1899, 450,588 tons, valued at £168,971. Fireclay as well as limestone is worked. Apart from the industries connected with agriculture, there are none of importance. The Haddington coast is embraced in the Leith fishery district, and the ports of the county are Dunbar, North Berwick, Port Seton, and Prestonpans, which had among them in 1899 179 boats of 2556 tons, and 669 resident fishermen and boys; and the value of the fish landed—chiefly cod, haddocks, whitings, and crabs—was £17,167. Of 4854 men in industrial employment in 1891, 1531 were engaged in raising minerals.

Haddington, a royal burgh and the county town of Haddingtonshire, Scotland, on the river Tyne, 17 miles east of Edinburgh by road, the terminus of a branch of the North British Railway. There are four bridges over the Tyne, and another is in course of construction, and the market cross has been restored. Haddington is the retail centre for a large district, and its grain markets, once the largest in Scotland, are still of considerable importance. The Knox Institute, built in 1880, contains a lecture room, and took the place of the ancient and famous grammar school. There is, besides, a public school, which had an average attendance of 457 in 1898–99, while a Roman Catholic school had 130. Population (1881), 4043; (1901), 3992.

Haeckel, Ernst Heinrich (1834– ——), German biologist, was born at Potsdam on 16th February 1834. He studied medicine and science at Würzburg, Berlin, and Vienna, having for his masters such men as Johannes Müller, Virchow, and Kölliker, and in 1857 graduated at Berlin as M.D. and M.Ch. At the wish of his father he began to practise as a doctor in that city, but his patients were few in number, one reason being that he did not wish them to be many, and after a short time he turned to more congenial pursuits. In 1861, at the instance of Gegenbaur, he became *privat-docent* at Jena; in the succeeding year he was chosen extraordinary professor of comparative anatomy and director of the Zoological Institute in the same university; in 1865 he was appointed to a chair of zoology which was specially established for his benefit. This last position he continued to retain in spite of repeated invitations to migrate to more important centres, such as Strassburg or Vienna, and at Jena he has spent his life, with the exception of the time devoted to travelling in various parts of the world, whence in every case he brought back a rich zoological harvest.

As a field naturalist Haeckel displayed extraordinary power and industry. Among his monographs may be mentioned those on *Radiolaria* (1862), *Siphonophora* (1869), *Monera* (1870), *Calcareous Sponges* (1872), and *Arabian Corals* (1876), as well as several *Challenger* reports, viz., *Deep-Sea Medusæ* (1881), *Siphonophora* (1888), *Deep-Sea Keratosa* (1889), and *Radiolaria* (1887), the last being accompanied by 140 plates and enumerating several thousand new species. This output of systematic and descriptive work would alone have constituted a good life's work, but Haeckel has in addition written copiously on biological theory. It happened that just when he was beginning his scientific career Darwin's *Origin of Species* was published (1859), and such was the influence it exercised over him that he became the apostle of Darwinism in Germany. He was, indeed, the first German biologist to give a whole-hearted adherence to the doctrine of organic evolution and to treat it as the cardinal conception of modern biology. It was he who first brought it prominently before the notice of German men of science in his memoir on the *Radiolaria*, which was completely pervaded with its spirit, and later at the Congress of Naturalists at Stettin in 1863. Darwin himself has placed on record the conviction that Haeckel's enthusiastic propagandism of the doctrine was the chief factor of its success in Germany. His book on *General Morphology* (1866), published when he was only thirty-two years old, was called by Huxley a suggestive attempt to work out the practical application of evolution to its final results; and if it does not take rank as a classic, it will at least stand out as a landmark in the history of biological doctrine in the 19th century. Although it contains a statement of most of the views with which Haeckel's name is associated, it did not attract much attention on its first appearance, and accordingly its author rewrote much of its substance in a more popular style and published it a year or two later as the *Natural History of Creation* (*Natürliche Schöpfungsgeschichte*), which was far more successful. In it he divided morphology into two sections—tectology, the science of organic individuality; and promorphology, which aims at establishing a crystallography of organic forms (see *Ency. Brit.*, vol. xvi. pp. 842–844). Among other matters, he laid particular stress on the "fundamental biogenetic law" that ontogeny recapitulates phylogeny, that the individual organism in its development is to a great extent an epitome of the form-modifications undergone by the successive ancestors of the species in the course of their historic evolution (*Ency. Brit.*, xx. p. 422). His well-known "gastraea" theory is an outcome of this generalization. He divided the whole animal creation into two categories—the Protozoa or unicellular animals, and the Metazoa or multicellular animals, and he pointed out that while the former remain single-celled throughout their existence, the latter are only so at the beginning, and are subsequently built up of innumerable cells, the single primitive egg-cell (*ovum*) being transformed by cleavage into a globular mass of cells (*morula*), which first becomes a hollow vesicle and then changes into the *gastrula*. The simplest multicellular animal he conceived to resemble this gastrula with its two primary layers, ectoderm and endoderm, and the earliest hypothetical form of this kind, from which the higher animals might be supposed to be actually descended, he called the "gastraea." This theory was first put forward in the memoir on the calcareous sponges, which in its sub-title was described as an attempt at an analytical

solution of the problem of the origin of species, and was subsequently elaborated in various *Studies on the Gastraea Theory* (1873–84). Haeckel, again, was the first to attempt to draw up a genealogical tree (*Stammbaum*) exhibiting the relationship between the various orders of animals with regard both to one another and their common origin. His earliest attempt in the *General Morphology* was succeeded by many others, but his efforts in this direction may perhaps be held to culminate in the paper he read before the fourth International Zoological Congress, held at Cambridge in 1898, when he traced the descent of the human race in twenty-six stages from organisms like the still-existing *Monera*, simple structureless masses of protoplasm, and the unicellular *Protista*, through the chimpanzees and the *Pithecanthropus erectus*, of which a few fossil bones were discovered in Java in 1894, and which he holds to be undoubtedly an intermediate form connecting primitive man with the anthropoid apes. In 1900 he made a voyage to Java and the East Indies for scientific purposes, and on his return published *Aus Insulinde, Malayische Reisebriefe* (1901).

Not content with the study of the doctrine of evolution in its zoological aspects, Haeckel also applied it to some of the oldest problems of philosophy and religion. What he terms the integration of his views on these subjects he published under the title of *Die Welt-räthsel*, which in 1900 appeared in English as *The Riddle of the Universe*. In this book he displays the courage of his convictions to an extent which the reader may feel ceases to be meritorious in the absence of adequate argument. Adopting an uncompromising monistic attitude, he asserts the essential unity of organic and inorganic nature. According to his "carbon-theory," which has been far from achieving general acceptance, the chemico-physical properties of carbon in its complex albuminoid compounds are the sole and the mechanical cause of the specific phenomena of movement which distinguish organic from inorganic substances, and the first development of living protoplasm, as seen in the *Monera*, arises from such nitrogenous carbon-compounds by a process of spontaneous generation. Psychology he regards as merely a branch of physiology, and psychical activity as a group of vital phenomena which depend solely on physiological actions and material changes taking place in the protoplasm of the organism in which it is manifested. Every living cell has psychic properties, and the psychic life of multicellular organisms is the sum-total of the psychic functions of the cells of which they are composed. Moreover, just as the highest animals have been evolved from the simplest forms of life, so the highest faculties of the human mind have been evolved from the soul of the brute-beasts, and more remotely from the simple cell-soul of the unicellular Protozoa. As a consequence of these views Haeckel is led to deny the immortality of the soul, the freedom of the will, and the existence of a personal God.

There is a biography by W. Bölsche (Dresden, 1900).

Hagen, an industrial town of Prussia, province of Westphalia, 15 miles by rail north-east of Elberfeld Barmen. It is the seat of important iron and cotton industries, and also of paper, cloth, and tobacco factories, tanneries, distilleries, and breweries. Among its principal buildings are the Luther church (1886–89), the Roman Catholic church (1895), and the royal engineering school (1891–1894). There are also a municipal park and a bronze statue of the Emperor Frederick III. (1899). Population (1885), 29,614; (1900), 50,609. In April 1901 the rural commune of Eckesey (12,326) was incorporated with Hagen, making the total population of Hagen and its environs 62.935.

Hagerstown, capital of Washington county, Maryland, U.S.A., west of the Blue Ridge, on the Baltimore and Ohio, the Norfolk and Western, the Western Maryland, and the Cumberland Valley railways, at an altitude of 567 feet. It is the seat of Kee Mar College, a Lutheran institution for women, established in 1852, and having, in 1898, 15 instructors and 110 students. Population (1880), 6627; (1890), 10,118; (1900), 13,591, of whom 394 were foreign-born and 1277 negroes.

Hagonoy, a town in the extreme south-western portion of the province of Bulacan, Luzon, Philippine Islands. It is the centre of a rich agricultural region, producing rice, Indian corn, coffee, and sugar. Alcohol is made in considerable quantities from the fermented juice of the nipa palm, which grows in the neighbouring swamps. The women of this town are very skilful in weaving the native fabrics. The language is Tagalog. Population, 20,000.

Hague, The (in Dutch *'S Gravenhage*, or *den Haag*), chief town of the province of South Holland (Netherlands), 13 miles N.W. of Rotterdam by rail. Its western portion being built upon high, dry, and sandy soil (the south and south-eastern on low-lying moorland), contains the healthiest, pleasantest, and most prosperous quarters, and the parks, gardens, and woods. The museums, libraries, scientific institutions, and art collections, and the attractiveness of the environs (Scheveningen, Wassenaer, Haagsche Bosch), make the town a popular resort for people of private means, ex-officials, colonials from India, artists, and scientific men, more especially as rents are low. Accordingly it has of late years grown more rapidly than any other in the kingdom, and many new streets and quarters have been built. Its industries have changed little, but the manufacture at Rozenburg of fine earthenware (Rozenburg-Delftsch) must be specially mentioned. A few buildings have been renewed or restored, among them the ministry of justice, the town hall, and the railway stations. The new buildings include one for the arts and sciences, a school for imbeciles, and one for technical instruction. A new fishing port is proposed near the end of the Hague-Scheveningen canal. Population (1869), 90,277; (1900), 206,023.

Hahn-Hahn, Ida, Countess (1805–1880), German authoress, was born at Tressow, in Mecklenburg-Schwerin, on 22nd June 1805. Her maiden name was Hahn, but she became Countess Hahn-Hahn on her marriage with her cousin in 1826. In 1829 the husband's irregularities led to a divorce. The countess travelled, produced some volumes of poetry indicating true lyrical feeling, and in 1838 appeared as a novelist with *Aus der Gesellschaft*, a title which, proving equally applicable to her subsequent novels, was retained as that of a series, the book originally so entitled being renamed *Ida Schönholm*. For several years the countess continued to produce novels bearing a certain subjective resemblance to those of George Sand, but less hostile to social institutions, and dealing almost exclusively with aristocratic society. The authoress's patrician affectations at length drew upon her the merciless ridicule of Fanny Lewald in a parody of her style entitled *Diogena* (1847), and this and the revolution of 1848 together seem to have co-operated in inducing her to embrace the Roman Catholic religion in 1850. She justified her step in a polemical work entitled *From Babylon to Jerusalem* (1851), which elicited a cutting reply from Professor Abeken. In 1852 she retired into a convent at Antwerp, but continued to write; her later publications, however, passed unnoticed as mere party manifestoes. Her earlier works do not deserve the neglect into which they have fallen. If their sentimentalism is some-

times wearisome, it is grounded on genuine feeling and expressed with passionate eloquence. *Ulrich* and *Faustine*, both published in 1841, mark the culmination of her power; but *Sigismund Forster* (1843), *Cecil* (1844), and *Sibylle* (1846) also obtained considerable popularity. She died at Mainz on the 12th of January 1880. (R. G.)

Haidarabad, or HYDERABAD, a native state of India, also known as the Nizam's Dominions and the Deccan, occupying the eastern portion of the plateau of Southern India. In 1887, on the occasion of Queen Victoria's Jubilee, the Nizam made an offer to the Viceroy of pecuniary aid for frontier defence, which led to the organization of the imperial service troops now maintained by several native chiefs. In 1900 he paid a visit to the Viceroy at Calcutta, being the first Nizam to leave his own dominions. The visit was returned by Lord Curzon in April 1902.

The following table gives the area and population of the several districts of Haidarabad state according to the census of 1901:—

Area and Population of Haidarabad, 1901.

Divisions.	Districts.	Area in Square Miles.	Number of Towns and Villages	Population, Census of 1901. Males.	Females.	Total.	Density of Population to Square Mile.	Population, Census of 1891.

The average density is 135 persons per square mile, ranging from 196 in Mehdak, on the west, to 53 in Sirpur Tandur, on the north. Classified according to religion, in 1891 Hindus numbered 10,315,249, or 89 per cent. of the total population. In the west they speak Marathi, in the south and east Telugu. Mahommedans numbered 1,138,666, or 10 per cent., being most numerous in Haidarabad city. Christians numbered 20,429, of whom half were Roman Catholics. Jains numbered 27,845; Sikhs, 4637; Parsis, 1058; Jews, 26; and aboriginal tribes, 29,130. The preliminary returns of the census of 1901 gave the total as 11,174,897, showing a decrease of 362,143, or 3 per cent., compared with an increase of 1,691,446, or 17 per cent., in the preceding decade. In some districts, where the famine of 1900 was most severe, the rate of decrease was as high as 20 per cent.

The yearly revenue of the state is estimated at Rs.4,00,00,000, of which about half is derived from the land. The Haidarabad Contingent consists of six regiments of cavalry, four batteries of artillery, and six battalions of infantry—total, 7660 men, all under British officers, maintained at a cost of about Rs.40,00,000. The currency is based on the *halli* rupee, which contains approximately the same weight of silver as the British rupee, but its exchange value has fallen heavily since the closing of the mints. The conventional rate of exchange is 128 *halli* rupees = 100 British rupees. An independent post-office is also maintained. Railways have been made by an English company under a guarantee from the state. The main line of the Great Indian Peninsula traverses the south-western corner of the state, whence a branch runs from Wadi to Haidarabad city, now continued through Warangal to Bezwada on the East Coast system. There is also a short branch to the Singareni coalfields. Another line was opened in 1900 in the north-east of the state, from Manmad junction by Aurangabad along the valley of the Godavery to Haidarabad city (386 miles). The total length of railway open in 1900 was 715 miles, the gross earnings being £422,102 and the net profits £205,400. The coal mine at Singareni is worked by an English company, employing 6800 persons, of whom 4860 are adult males. In 1898 the output was 394,622 tons, valued at Rs.11,83,870. Attempts to work gold and diamond mines have not been successful. There are three cotton mills, belonging to companies, at Haidarabad city, Aurangabad, and Gulbarga, with 623 looms and 52,476 spindles, employing 2480 hands. The state has suffered from bad seasons, which culminated in 1900 in actual famine. The total number of persons in receipt of relief rose to nearly 500,000 in June 1900.

The CITY OF HAIDARABAD is situated on the river Musi, about 1700 feet above the sea. Population, together with Secunderabad and the suburbs (1881), 367,417; (1891), 415,039; (1901), 446,291. Haidarabad is thus the fourth most populous city in India, being surpassed only by the three Presidency towns, which are all seaports. The city proper is surrounded by a stone wall, with a circuit of about 6 miles. Secunderabad (6 miles) is the headquarters of a first-class military district under the Madras command. A little farther north (9 miles) is Bolaram, another military cantonment. The old fortress of Golconda, now used as a state treasury and prison, is about 7 miles to the west.

J. B. GRIBBLE. *A History of the Deccan.* London, 1896.

(J. S. CO.)

Haidarabad, or HYDERABAD, a city and district of British India, in the Sind province of Bombay. The city is on a hill about 3 miles from the left bank of the Indus, and had a population in 1881 of 48,153, and in 1891 of 54,048. An excellent water supply is derived from the Indus. Communication is maintained with the railway station of Kotri, on the opposite bank of the river, by a steam ferry from Gidu-Bandar; but the stream has been bridged, and a railway runs thence into Rajputana. There are manufactures of silk, gold, and silver embroidery, lacquered ware and pottery, and three factories for ginning cotton. It has three high schools, with about 800 pupils, training colleges for masters and mistresses, a medical school, an agricultural school for village officials,

a technical school, and three printing-presses, each issuing a vernacular periodical. The city suffered from plague in 1896–97, but the death-rate for 1897 was only 38·9 per 1000. The DISTRICT OF HAIDARABAD has an area of 9033 square miles, with a population in 1881 of 754,624, and in 1891 of 918,646, giving an average density of 102 persons per square mile, being the highest in Sind. In 1901 the population was 990,502, showing an increase of 1 per cent., compared with an increase of 16 per cent. in the previous decade. The land revenue was Rs.21,46,338, the incidence of assessment being Rs.2–5–6 per acre; the cultivated area in 1897–98 was 942,471 acres, of which 916,659 were irrigated, including 842,445 from Government canals; the number of police was 1174; the children at school in 1897–98 numbered 15,853, being 2·1 per cent. of the total population; the registered death-rate in 1897 was 14·4 per 1000. The principal crops are millet, rice, oil-seeds, cotton, and wheat. There is a special manufacture at Hala of glazed pottery and striped cotton cloth. A railway crosses the district eastwards from Haidarabad to Shadipalli, which will be extended across the Indus on one side and into Rajputana on the other, thus affording a direct route, on the metre gauge, from Northern India nearly to Karachi.

Haifa, a coast town of Palestine, situated at the foot of Mount Carmel, on the south side of the bay of Acre. Its roadstead is protected from south and west winds, and the town, from its more favourable position, is attracting much of the trade of Acre. A railway to Damascus has been commenced, and it is proposed to construct a port. If these works are completed, Haifa will become the most important port on the coast of Syria. The German colony of "Templars," established near the town in 1869, has been the means of greatly increasing its prosperity. In 1900 the exports, cereals and oil, were valued at £178,738. The population numbered 12,000 (Germans 500, Moslems 6000, Christians 4000, Jews 1500). About 2 miles north-west of Haifa is the celebrated Carmelite monastery.

(C. W. W.)

Hainan, a large island off the southern coast of China, forming part of the province of Kwangtung. The trade of Kiungchow, which is the only treaty port in the island, has risen from 1,215,000 Haikwan taels, or £175,300, in 1878 to 4,647,000 Haikwan taels, or £670,600, in 1899. This trade is almost entirely with the British colony of Hong Kong, with which the port is connected by small coasting steamers, but since 1893 it has had regular steamboat communication with Haiphong in Tongking. The population of Kiungchow, including its shipping port of Hoihow, is estimated at 52,000. The number of foreign residents in 1900 was about 30, most of them officials or missionaries.

Hainaut (French, *Hainaut;* Flemish, *Henegouwen*), a Belgian province bordering on West and East Flanders, Brabant, Namur, and the French department Du Nord. A part of the ancient Countship of Hainaut of the 9th century, it was under the government of France known as the "departement de Jemappes"—the name of a place where the French arms were victorious in 1792. The land rises in a southerly direction up to a height of 1200 feet. The western half of the province belongs to the basin of the Scheldt, the eastern half to the basin of the Meuse. These two basins communicate with one another by the Charleroi canal. In the way of mineral products, coal is extracted in the three regions of Borinage, Centre, and Charleroi basins, the mining employing 83,000 workers. The province has also quarries of marble, of building-, paving-, and lime-stone, employing 11,000 workers. The crops include cereals, beetroot, flax, hemp, and tobacco. Though agriculture is in a high state of excellence, the province is essentially industrial. The principal industries are: metallurgy in all its branches, employing 24,000 workers—rolling mills, steam engines, railway material, &c.; glass works, employing 14,000 persons; numerous sugar refineries, chemical works, &c. The province is divided into six administrative arrondissements. The chief towns are: Mons (55,600 inhabitants), capital of the province; Tournai (36,800), Charleroi (24,400); and, among the industrial towns, Jumet (25,000), La Louvière (16,000). The province covers 1437 square miles, with (1899) a population of 1,133,672, or 789 to the square mile. Between 1876 and 1899 the population of the province decreased 177,318, having been at the former date 956,354.

Haiphong, a town in Tongking, French Indo-China, on one of the branches of the Song-Koi (or Red River) delta. So recently as 1880 wide marshes and submerged rice-fields extended round the junction of the Kwa-Kam and the Song Tam Bac mouths of the Red River. On the same site to-day stands Haiphong, the largest town of Tongking with the exception of Hanoi. It has a population of about 17,000, of whom 630 are European (exclusive of officials and the garrison) and 5000 Chinese, and is the great port of Tongking. Since 1893 the opening of navigation on the Red River and the establishment of regular services to Hong Kong, Pakhoi, and Hoihow (on Hainan island) has greatly increased the traffic. The steamers to the interior of Tongking number more than 1800 entering and clearing. The excavation of the Kwa-Nam-Triu, in course of completion, will permit the largest vessels to reach Haiphong without being delayed by the bar. The town was constituted a municipality 19th July 1888. Since 1893 it has been lighted by electricity. There are extensive artillery workshops and military stores in the Annamese citadel. Haiphong is a naval station for warships on the reserve and for dismantled gunboats. The streets are regularly laid out and planted with trees. The Boulevard Paul Bert is the finest European street. The most noteworthy buildings are the Residency, the tribunal, the Indo-Chinese Bank, the Treasury, and the mansion of the Governor-General. There are also fine promenades and a race-course, and the town boasts three printing-offices and three French newspapers. Fourteen miles from Haiphong, along a fairly good road, lies the bathing resort of *Do-Son,* the only seaside town in Tongking in which sea-bathing can be enjoyed. The Governor-General has a villa there. Since 1891 many houses have been built, and the beach has been much frequented. All the great Indo-Chinese banks have branch establishments at Haiphong, and its chamber of commerce is of sufficient importance to entitle its president to a seat upon the superior council of Indo-China.

(J. M. A. DE L.)

Hajipur, a town of British India, in the Muzaffarpur district of Bengal, on the Gandak, just above its confluence with the Ganges above Patna. It is the terminus of the branch of the Tirhut Railway from Muzaffarpur, and of another branch under construction along the Ganges to Katihar. Population (1881), 25,078; (1891), 21,487.

Hakata. See FUKUOKA.

Hake, Thomas Gordon (1809–1895), English poet, was born at Leeds in 1809. A physician by profession, he had given up practice for many years before his death, and had devoted himself to a literary life. In 1839 he published a prose epic *Vates,* which attracted the attention of D. G. Rossetti, and in after years he became

an intimate member of Rossetti's circle of friends and followers. In 1871 he published *Madeline*, (1873) *Parables and Tales*, (1883) *The Serpent Play*, (1890) *New Day Sonnets*, and in 1892 he published his *Memoirs*. Dr Hake's works had much subtlety and felicity of expression, and were warmly appreciated in a somewhat restricted literary circle. He was given a Civil List literary pension in 1893, and died on 11th January 1895.

Hakodate, a town on the south-east of the island of Yezo, Japan, situated in 41° 46′ N. lat. 140° 44′ E. long., for many years regarded as the capital of the island until Sapporo was officially raised to that rank. It is one of the ports originally opened to foreign trade, and the development of its commerce is exhibited in the following table :—

Year.	Exports.	Imports.	Total.
1884	£67,663	£898	£68,561
1889	126,858	19,105	145,963
1893	79,953	3,040	82,993
1899	211,605	172,646	384,251

The staple exports are beans, pulse, and peas, marine products, sulphur, furs, and timber; the staple imports, comestibles (especially salted fish), kerosene, and oil-cake. The town is not situated so as to profit largely by the development of the resources of Yezo. The population grew from 55,677 in 1890 to 78,040 in 1899, and its prosperity has increased in a corresponding ratio, but as a port for foreign trade its outlook is indifferent. Good steamers ply between Hakodate and Yokohama twice or thrice a week, and there is daily communication with Aomori, 56 miles distant, whence train may be taken for Tôkyô. Hakodate has now a tramway, and is provided with waterworks, the water being carried from the Aka-gawa, 7 miles distant. A fort has been constructed near the summit of the Peak, a great rock which has been likened to Gibraltar, and it is consequently no longer accessible to viewgazers.

Hal, a town of Belgium, in the province of Brabant, 10 miles south of Brussels by rail. It has several industries, including the manufacture of beetroot sugar, considerable beer brewing, and the building of canal boats. Population (communal, 1899), 12,026.

Halberstadt, a town of Prussia, province of Saxony, 56 miles by rail N.W. of Halle. Gleim's house became the property of the municipality in 1899. The leading industries are the manufacture of cigars, gloves, and sugar, distilling, brewing, and tanning. There are also large railway workshops. Population (1885), 34,025; (1900), 42,644.

Halévy, Ludovic (1834– ——), French author, was born in Paris on the 1st of January 1834. His father, Léon Halévy, was a clever and versatile writer, who tried almost every branch of literature—prose and verse, vaudeville, drama, history—without, however, achieving decisive success in any. His uncle, Fromental Halévy, the celebrated author of *La Juive*, was for many years *directeur du chant* at the Opéra; hence the double and early connexion of Ludovic Halévy with the Parisian stage. At the age of six he might have been seen playing in that *Foyer de la danse* with which he was to make his readers so familiar, and, when a boy of twelve, he would often, of a Sunday night, on his way back to the College Louis le Grand, look in at the Odéon, where he had free admittance, and see the first act of the new play. At eighteen he joined the ranks of the French administration and occupied various posts, the last being that of secrétaire-rédacteur to the Corps Législatif. In that capacity he enjoyed the special favour and friendship of the famous duke of Morny, then President of that assembly. In 1865 Ludovic Halévy's increasing popularity as an author enabled him to retire from the public service. Ten years earlier he had become acquainted with the musician Offenbach, who was about to start a small theatre of his own in the Champs Élysées, and he wrote a sort of prologue, *Entrez, messieurs, mesdames*, for the opening night. Other little productions followed, *Ba-ta-clan* being the most noticeable among them. They were produced under the pseudonym of Jules Servières. The name of Ludovic Halévy appeared for the first time on the bills on the 1st of January 1856. Soon afterwards the unprecedented run of *Orphée aux Enfers*, a musical parody, written in collaboration with Hector Crémieux, made his name famous. In the spring of 1860 he was commissioned to write a play for the manager of the *Variétés* in conjunction with another vaudevillist, Lambert Thiboust. The latter having abruptly retired from the collaboration, Halévy was at a loss how to carry out the contract, when on the steps of the theatre he met Henri Meilhac (1831–1897), then comparatively a stranger to him. He proposed to Meilhac the task rejected by Lambert Thiboust, and the proposal was immediately accepted. Thus began a connexion which was to last over twenty years, and which proved most fruitful both for the reputation of the two authors and the prosperity of the minor Paris theatres. Their joint works may be divided into three classes: the *opérettes*, the farces, the comedies. The *opérettes* afforded excellent opportunities to a gifted musician for the display of his peculiar humour. They were broad and lively libels against the society of the time, but savoured strongly of the vices and follies they were supposed to satirize. Amongst the most celebrated works of the joint-authors were *La Belle Hélène* (1864), *Barbe Bleue* (1866), *La Grande Duchesse de Gerolstein* (1867), and *La Périchole* (1868). After 1870 the vogue of Parody rapidly declined. The decadence became still more apparent when Offenbach was no longer at hand to assist the two authors with his quaint musical irony, and when they had to deal with interpreters almost destitute of singing powers. They wrote farces of the old type, consisting of complicated intrigues, with which they cleverly interwove the representation of contemporary whims and social oddities. They generally failed when they attempted comedies of a more serious character and tried to introduce a higher sort of emotion. A solitary exception must be made in the case of *Frou-frou* (1869), which, owing perhaps to the admirable talent of Aimée Desclée, remains their unique *succès de larmes*.

Meilhac and Halévy will be found at their best in light sketches of Parisian life, *Les Sonnettes*, *Le Roi Candaule*, *Madame attende Monsieur*, *Toto chez Tata*. In that intimate association between the two men who had met so opportunely on the *perron des Variétés*, it was often asked who was the leading partner. The question was not answered until the connexion was finally severed and they stood before the public, each to answer for his own work. It was then apparent that they had many gifts in common. Both had wit, humour, observation of character. Meilhac had a ready imagination, a rich and whimsical fancy; Halévy had taste, refinement, and pathos of a certain kind. Not less clever than his brilliant comrade, he was more human. Of this he gave evidence in two delightful books, *Monsieur et Madame Cardinal* and *Les petites Cardinal*, in which the lowest orders of the Parisian middle class are faithfully described. The pompous, pedantic, venomous Monsieur Cardinal will long survive as the true image of sententious and self-glorifying immorality. M. Halévy's peculiar qualities are even more visible in the simple and striking scenes of the *Invasion*, published soon after the conclusion of the

Franco-German war, in *Criquette* and *L'Abbé Constantin* (1882), two novels, the latter of which went through innumerable editions. Zola had presented to the public an almost exclusive combination of bad men and women; in *L'Abbé Constantin* all are kind and good, and the change was eagerly welcomed by the public. Some enthusiasts still maintain that the *Abbé* will rank permanently in literature by the side of the equally chimerical *Vicar of Wakefield.* At any rate, it opened for M. Ludovic Halévy the doors of the French Academy, to which he was elected in 1888.

Hale, Edward Everett (1822- ——), American author and Unitarian minister, was born in Boston, 3rd April 1822, being the son of Nathan Hale, editor of the Boston *Daily Advertiser*, and the nephew of Edward Everett, the orator and statesman. He graduated at Harvard in 1839, entered the Unitarian ministry, and, after a pastorate in Worcester, Massachusetts, became minister of the South Congregational (Unitarian) Church in Boston in 1856. There he remained until his resignation in 1899. While he always deemed his life-work to be that of a Christian minister, and his strong personality affected New England life for half a century, he was a constant and voluminous contributor to the periodical press; he edited many magazines and newspapers, of which the monthly *Old and New* was the most ambitious; and is the author or editor of sixty or seventy volumes — fiction, juvenile stories, books of travel, sermons, biography, and history. His best-known short story is *The Man without a Country*, which, published in the *Atlantic Monthly* in 1863, at the darkest period of the American Civil War, did much to strengthen the Union cause in the North. In this, and in some of his other non-romantic tales, he employed a minute realism which led many readers to suppose the narrative a record of unaltered fact. The story *Ten Times One is Ten* (1870), with its hero Harry Wadsworth and its motto, "Look up and not down, look out and not in, look before and not behind, and lend a hand," led to the formation, in many parts of the United States, of "Lend a Hand Clubs," "Look-up Legions," or "Harry Wadsworth Clubs"; while out of the romantic Waldensian religious story *In His Name* (1874) there similarly grew orders of "King's Daughters," "King's Sons," and other organized bodies for religious work. Of his other writings in prose and verse—all marked by abounding vivacity, earnest humanity, and rapidity of workmanship—the most important are the two volumes, largely based on painstaking original research, in collaboration with his son, Edward Everett Hale, Jun., on *Franklin in France* (1887–88: Part I. "The Alliance"; Part II. "The Treaty of Peace and Franklin's Life till his Return"); the autobiographical record of his own *New England Boyhood* (1893) in Boston in the 'twenties and 'thirties; and the account, from first-hand sources and personal knowledge, of *James Russell Lowell and his Friends* (1899). Dr Hale interested himself successively in the anti-slavery movement, the protective tariff, popular education, and working-men's home life. A collected and revised edition of his writings began to appear in 1899.

Halfaya, a historical town of Anglo-Egyptian Sudan, which gives its name to the district of Khartum. For several years after its occupation by the Egyptians (1821) it continued to be the chief station about the confluence of the Blue and White Niles. It stands 7 miles above the confluence, and before the Mahdist revolt was the residence of the powerful sheikh of the Jalin Arabs. But it lost most of its importance when the seat of government was removed by Mehemet Ali to Khartum.

Halicz, a town in the government district of Stanislau, Galicia, Austria, at the confluence of the Luckow with the Dniester. It is commanded by the ruins of the old castle of Halicz, the seat of the ruler of the former kingdom from which Galicia has derived its Polish name. Its principal resources are the recovery of salt from the neighbouring brine wells, soap-making, and the trade in timber. Population (1890), 3887; (1900), 4809.

Halifax, a municipal, county (1888), and parliamentary borough of the West Riding of Yorkshire, England, on the Hebble near its influx into the Calder, 7 miles south-west by west of Bradford, 209 miles by rail north-north-west of London. The municipal borough is divided into 15 wards under a mayor, 15 aldermen, and 45 councillors. The corporation possesses waterworks, gasworks, electric works, tramways, a bonding warehouse, two public libraries, an art gallery and museum (1886), a technical school (1895, costing over £26,000), a court house and police station, erected at a cost of £27,000, a fire brigade station, and six parks. Modern public buildings include the handsome post office (1887), a new infirmary (1896), and a higher-grade board school. There are two newspapers. The manufacture of carpets is a large industry, one establishment employing 5000 hands. In 1891, 2280 persons were employed in the making of machines, 4070 males and 7506 females in the worsted, 1365 males and 965 females in the woollen, 1159 males and 1364 females in the cotton, and 970 persons in the iron and steel manufacture. The municipal and county borough, coextensive with the parliamentary borough till 1892, was extended then, and again in 1900, and now has an area of 13,636 acres. Population (1891), 97,714; (1901), 104,933.

Halifax, city and port of entry, the capital of Nova Scotia and of Halifax county, on the south-east coast of the province. Recent improvements are the new Dalhousie College, the Intercolonial Railway station, a dry dock constructed by a company with Imperial, Dominion, and civic subsidies, having a capacity for ships of 600 feet in length, and used by the Admiralty and by the Government of the United States for repairing ships of war; spacious wharves, warehouses, freight sheds, &c., and a grain elevator with a capacity of some 750,000 bushels, constructed at the deep-water terminus of the Intercolonial Railway; armouries for the militia, and a new building for the school for deaf and dumb. There are twenty-six churches, five banks, and branches of two others. Halifax is the American terminus of the Direct Cable Company. It is one of the termini of the subsidized mail steamers plying between Great Britain and Canada, and secures a portion of the winter trade. The city is lighted by gas and electricity, and an electric street railway traverses the principal streets. In 1900 there were 148 teachers employed and 7988 pupils attended the city schools, being 1 in 4·8 of the population. There are two manual training schools, one for boys and one for girls. In 1900 the number of British and foreign vessels entered was 1080, tonnage 866,989; cleared 1185, tonnage 840,796. Moreover, in connexion with the coasting trade 4030 vessels of 495,394 tons entered in 1900, and 3790 of 529,284 tons cleared. The net debt in 1899 was $3,153,516, taxable property $23,260,962. Exports in 1890 were valued at $5,292,498, in 1900 at $6,758,403; imports in 1890 at $6,669,858, in 1900 at $6,335,691. Population (1881), 36,100; (1891), 38,495; (1901), 40,787.

Hall, a town in northern Tirol, Austria, on the left bank of the Inn, 4 miles east of Innsbruck. Among its new industries are corn-milling, the manufacture of felt hats, bone buttons, and fire-engines. An important

feature of the town is its growing popularity as a health resort, its brine and mineral springs possessing valuable properties. Population, Roman Catholic and German (1890), 5763; (1900), 6191.

Hall, or BAD-HALL, a market-place and spa in the government district of Steyr, Upper Austria. Its saline springs, strongly impregnated with iodine and bromine, have been known since the 9th century, and have the reputation of being very efficacious in scrofulous affections and venereal skin diseases. There is a kurhaus, a children's hospital, and a bathing establishment for poor patients. It is annually visited by about 3500 patients. Population (1890), 866; (1900), 984.

Hall, Christopher Newman (1816–1902), English Congregational divine, son of the proprietor and printer of the *Maidstone Journal*, was born at Maidstone on 22nd May 1816, and educated at Totteridge and Highbury College. He also attended classes at University College, and took the London B.A. degree. Like the other students of Highbury College, he was often sent to preach at different towns, and had already acquired some practice when he was called (1842) to his first pastorate at the Albion Congregational Church at Hull. During the twelve years of his ministry the membership was greatly increased, and a branch chapel and school were opened. At Hull Newman Hall first began his active work in temperance reform, and in defence of his position wrote the *Scriptural Claims of Teetotalism.* In 1854 he accepted a call to Surrey Chapel, London, founded in 1783 by the Rev. Rowland Hill. A considerable sum had been bequeathed by the latter for the perpetuation of his work on the expiration of the lease; but, owing to some legal flaw in the will, the money was not available, and Newman Hall undertook to raise the necessary funds for a new church. By weekly offertories and donations the money for the fine new church at the junction of the Kennington and Westminster Bridge Roads was collected, and within four years of opening (1876) the total cost (£63,000) was cleared. In 1892 Newman Hall resigned his post, and afterwards devoted himself to general evangelical work. Most of his writings are small booklets or tracts of a distinctly evangelical character. The best known of these is *Come to Jesus*, of which no fewer than four million copies were circulated in forty different languages. Newman Hall visited the United States during the Civil War, and did much to promote a friendly understanding between England and America. A Liberal in politics, and a keen admirer of John Bright, few preachers of any denomination have exercised so far-reaching an influence as "the Dissenters' Bishop," as he came to be termed. He died 18th February 1902.

Halle, a town of Prussia, province of Saxony, 21 miles by rail north-west of Leipzig on the way to Magdeburg, and on the river Saale. The oldest parts of the town, between the churches of St Mary and St Maurice, have been modernized by driving some new streets through them. The town council assembly rooms were built in 1890–92, the front being adorned with statues of Charlemagne, the Great Elector, King Frederick I., and the Emperor William I.; and the town hall was in part restored in 1884. Amongst the public institutions should be mentioned the archæological museum (opened in 1891), the industrial art museum, the provincial museum and mineralogical museum (these two in the former palace of the archbishops of Magdeburg), the numerous medical institutes (which make up a quarter by themselves, on the east side of the town), the agricultural institute belonging to the university—one of the foremost institutions of the kind in Germany—the institute of physics with a meteorological institute, the convict prison, the Leopoldine Carolinian Academy, the provincial blind asylum (brought hither from Barby), the Riebeck old age asylum (1894–96), the new theatre (1886), the church of St Stephen's (1894) and the church of St John's (1893), a monument to the surgeon von Volkmann (1894), and the Gothic church of St Francis and St Elizabeth (1894–96). A new building was completed for the university library in 1880. A handsome new central railway station was opened on the east of the town in 1890, its cost being over half a million sterling. In 1900–1 the university was attended by 1620 students, and had 155 professors. Of late Halle has assumed the character and appearance of a manufacturing town, the principal establishments being sugar and starch factories, engineering works, factories for making agricultural machinery, printing works, breweries, distilleries, chemical factories, and salt works (some 8500 tons of salt being produced annually). In 1900 the town was enlarged by the incorporation of the communes of Giebichenstein (15,072 in 1895), Trotha (3656), Cröllwitz (2861), and Gimritz (90). Giebichenstein has a saline spring, which is visited by nearly 1000 persons annually, and is a favourite summer resort of the people of Halle, as is also the green island of Peissnitz, or the Nightingale Island, on the west of the town. Population (1885), 81,982; (1895), 116,304; (1900), 156,611.

Hallé, Sir Charles [originally KARL HALLE] (1819–1895), the eminent pianist and conductor, was born at Hagen, in Westphalia, 11th April 1819. He studied under Rink at Darmstadt in 1835, and as early as 1836 went to Paris, where for twelve years he lived in constant intercourse with Cherubini, Chopin, Liszt, and other musicians, and enjoyed the friendship of the great literary lights of the time, such as Alfred de Musset and George Sand. He had started a set of chamber concerts with Alard and Franchomme with great success, and had completed one series of them when the revolution of 1848 drove him from Paris, and he settled, with his wife and two children, in London. His pianoforte recitals, given at first from 1850 in his own house, and from 1861 in St James's Hall, were an important feature of London musical life, and it was due in great measure to them that a knowledge of Beethoven's pianoforte sonatas became general in English society. At the Musical Union founded by John Ella, and at the Popular Concerts from their beginning, Hallé was a frequent performer, and from 1853 was director of the Gentlemen's Concerts in Manchester, where, in 1857, he started a series of concerts of his own, raising the orchestra to a pitch of perfection quite unknown at that time in England. In 1888 he married Madame Norman Néruda, the famous violinist, and in the same year was knighted; in 1890 and 1891 he toured with his wife in Australia and elsewhere. He died at Manchester, 25th October 1895. Hallé was one of the most important influences in the musical education of England; if his pianoforte-playing, by which he was mainly known to the public in London, seemed remarkable rather for precision than for depth, for crystal clearness rather than for warmth, and for perfect realization of the written text rather than for strong individuality, it was at least of immense value as giving the composer's idea with the utmost fidelity. Those who were privileged to hear him play in private, like those who could appreciate the power, beauty, and imaginative warmth of his conducting, would have given a very different verdict; and they were not wrong in judging Hallé to be a man of the widest and keenest artistic sympathies, with an extraordinary gift of insight into music of every school, as well as a strong sense of humour. He fought a long and arduous

battle for the best music, and never forgot the dignity of his art. In spite of the fact that his technique was that of his youth, of the period before Liszt, the ease and certainty he attained in the most modern music was not the less wonderful because he concealed the mechanical means so completely. (J. A. F. M.)

Hallgrímsson, Jónas (1807–1844), the chief lyrical poet of Iceland, was born in 1807 at Steinsstaðir in Eyjafjarðarsýsla in the north of that island, and educated at the famous school of Bessastaðr. In 1832 he went to the University of Copenhagen, and shortly afterwards turned his attention to the natural sciences, especially geology. Having obtained pecuniary assistance from the Danish Government, he travelled through all Iceland for scientific purposes in the years 1837–1842, and made many interesting geological observations. Most of his writings on geology are in Danish. His renown was, however, not acquired by his writings in that language, but by his Icelandic poems and short stories. He was well read in German literature, Heine and Schiller being his favourites, and the study of the German masters and the old classical writers of Iceland opened his eyes to the corrupt state of Icelandic poetry and showed him the way to make it better. The misuse of the Eddic metaphors made the lyrical and epical poetry of the day hardly intelligible, and, to make matters worse, the language of the poets was mixed up with words of German and Danish origin. The great Danish philologist and friend of Iceland, Rasmus Rask, and the poet Bjarni Thórarensen had done much to purify the language, but Jónas Hallgrímsson completed their work by his poems and tales, in a purer language than ever had been written in Iceland since the days of Snorri Sturluson. The excesses of Icelandic poetry were specially seen in the so-called *rímur*, ballads of heroes, &c., which were fiercely attacked by Jónas Hallgrímsson, who at last succeeded in converting the educated to his view. Most of the principal poems, tales, and essays of Jónas Hallgrímsson appeared in the periodical *Fjölnir*, which he began publishing at Copenhagen in 1835, together with Konráð Gíslason, a well-known philologist, and the patriotic Thómas Sæmundsson. *Fjölnir* had in the beginning a hard struggle against old prejudices, but as the years went by its influence became enormous; and when it at last ceased, its programme and spirit still lived in *Ný Félagsrit* and other patriotic periodicals which took its place. Jónas Hallgrímsson, who died in 1844, is the father of a separate school in Icelandic lyric poetry. He introduced foreign thoughts and metres, but at the same time revived the metres of the Icelandic classical poets. Although his poetical works are all comprised in one small volume, he strikes every string of the old harp of Iceland. (S. BL.)

Halliwell-Phillips, James Orchard (1820–1889), English Shakespearean scholar, son of Thomas Halliwell, was born in London, 21st June 1820, and educated privately and at Jesus College, Cambridge. He devoted himself to antiquarian research, particularly in early English literature. In 1839 he edited Sir John Mandeville's *Travels;* in 1842 published an *Account of the European MSS. in the Chetham Library*, besides a newly discovered metrical romance of the 15th century (*Torrent of Portugal*). He became best known, however, as a Shakespearean editor and collector. In 1848 he brought out his *Life of Shakespeare*, which passed through several editions; in 1853–65 a subscription edition of the works in folio; in 1863 a *Calendar of the Records at Stratford-on-Avon;* in 1864 a *History of New Place.* He was mainly instrumental in the purchase of New Place for the Corporation of Stratford-on-Avon, and in the formation there of the Shakespeare Museum. His publications in all numbered more than sixty volumes. He assumed the name of Phillips in 1872, under the will of the grandfather of his first wife, a Worcestershire heiress. His house, Hollingbury Copse, near Brighton, was full of rare and curious works, and he generously left many of them to the public. He died 3rd January 1889.

Hallstatt, a market-place in the government district of Gmunden, Upper Austria, on the lake of the same name. The salt mine of Hallstatt, which is one of the oldest in existence, was rediscovered in the 14th century. The neighbourhood (evidently an ancient Celtic settlement) is further remarkable for the great number of antiquities of the Roman and still earlier periods which have been found there. These comprise ornaments and other objects in bronze, iron, gold, pottery, glass, amber, and ivory. (See works by Baron von Sacken, and Meyer on *Das Gräberfeld von Hallstatt.*) Some of these relics have been retained in the Hallstatt Museum, but the most important have been removed to the Natural History Museum in Vienna and the provincial museum at Linz. Population (1890), 789; (1900), 737—all German, two-thirds Catholic and one-third Protestant.

Halmahera, or JILOLO, an island in the East Indian Archipelago, east of the north part of Celebes, belonging to the Dutch residency of Ternate. Without the neighbouring islands its area is 6648 square miles; with them, 7495 square miles. Of its four peninsulas, the northern and the southern are reckoned to the sultanate of Ternate, the north-eastern and south-eastern to that of Tidore; the former having eleven, the latter three districts. Since 1879, Campen's explorations in the north and Kükenthal's on the south-eastern peninsula have added to our still very incomplete knowledge of the island. According to Campen, the four peninsulas are traversed in the direction of their longitudinal axis by mountain chains 3000 to 4000 feet high, covered with forest, without a central chain at the nucleus of the island whence the peninsulas diverge. The mountain chains are frequently interrupted by plains, such as those of Wadyi and Kobee. The northern part of the mountain chain of the northern peninsula is volcanic, its volcanoes, Sallo (better, Tallama Kiëé), Onu, Ibu, &c., being a continuation of the volcanoes of Makian, Ternate, and Tidore. Coral formations on heights in the interior would indicate oscillations in several periods, but a detailed geology of the island is still wanting. Besides sago and rice, the island grows dammar and cocoanuts. The sea also yields trepang and pearl shells. A little trade is carried on by the Chinese and Makassars of Ternate, who, crossing the narrow isthmus of Dodinga, enter the bay of Kayu on the east coast. The population is estimated at 30,000, the greater part in the northern peninsula, predominantly Mahommedans.

In a Dutch work, *The Century of Missionary Labour in Netherlands-India* (Utrecht, 1901), Mr Coolsma shows that the Dutch Missionary Society of Utrecht, who have worked in the northernmost peninsula since 1866, have been fairly successful among the savage Alfoors (slave-drivers and head-hunters like their Borneo kinsmen), but less so among the Mahommedans, who have often incited the Alfoors against them and their converts. At the end of 1900 the latter numbered 3000. The influence of the Dutch Government over the sultans of Ternate and Tidore has steadily increased. The pirates of Tobèlo have been virtually extirpated since the Dutch expedition of 1878. But slavery still exists in the interior.

Halmstad, a seaport town of Sweden, on the east shore of the Cattegat, 76 miles south-south-east of Gothenburg by rail. It possesses cloth, jute, hat, wood-pulp, moss litter, and paper factories, in addition to foundries,

engineering shops, shipbuilding yards, glass-works, granite quarries, and breweries; and is famous for its potatoes and its salmon. It has a growing trade in the export of granite, timber (1,980,000 cubic feet in 1888, 8,000,000 in 1899), wood-pulp, and hats. The granite goes almost entirely to Germany. Butter is extensively made in the district, but is exported through Gothenburg and Helsingborg. The imports consist principally of coal (55,000 tons in 1899), machinery, and grain. The port was cleared by 1098 vessels, of an aggregate of 93,600 tons, in 1888; and by 2035 vessels, of 188,500 tons, in 1900. The harbour, which is accessible in all weathers, was widened and deepened in 1888–89. There are an inner harbour, 15 feet deep, an outer harbour, and roads giving anchorage in 24 to 36 feet, but exposed to south and north-west winds. Population (1880), 8505; (1900), 15,362.

Halos.—The refraction of sunlight or moonlight, through ice-crystals forming cirrus clouds, gives rise to coloured *Halos*, *Parhelia*, *Paraselenæ*, &c. Halos are at once distinguished from rainbows, for they surround the luminary, while the primary and secondary rainbows, at least, have their centres opposite to it.

The usual form of ice-crystals in the air is a regular hexagonal prism, terminated by plane ends perpendicular to the axis. Sometimes the prisms are long and narrow, sometimes they are mere hexagonal plates. Two alternate faces of the hexagon give an ice-prism of 60°, a face and an end a prism of 90°. The refractive index of ice is about 1·31. Let us study the effects of innumerable prisms having these angles, and falling in all aspects or positions in the quarter where the sun appears to be situated. The result of an average distribution will, of course, be symmetrical with regard to the line joining the eye and the sun, and the refracted rays will be crowded together in the direction of minimum deviation. The minimum deviation produced by an ice-prism of 60° is the angle 22° very nearly; and for a prism of 90°, about 46°. This is, of course, on the supposition that the refraction is in a plane perpendicular to the edge of the prism. Hence if we consider one kind of homogeneous light only, the sun should appear to be surrounded by two circular rings of light, each of a breadth equal to the sun's apparent diameter, and of mean angular radii 22° and 46° respectively. As these are due to the minimum of deviation by each class of prisms, the scattered rays directly refracted by any one of the prisms, as well as the rays which have passed obliquely through it, are seen *outside* the corresponding halo. The minimum deviation will be least for the least refrangible rays, so that in both these halos the red rays form the *interior* border. In this respect they resemble the secondary, not the primary, rainbow. The cause which produces impurity of the colours of the rainbow affects those of the halos even more profoundly. In fact, only the red is at all pure, and the overlapping (due partly to the sun's diameter, but still more to oblique refraction) is so great that, as a rule, a mere trace of green and blue can be seen, the external portion of each halo being nearly white. This gives the phenomenon a very singular character.

Let us now take account of the fact that the crystals free in air will, on the whole, tend to fall in one or more particular positions, *i.e.*, the long prisms mainly endwise, or it may be with their axes horizontal; the plates flatwise, or edgewise, as the case may be. The effect will be to intensify those parts of the halo which are due to the majority of the crystals. When the sun is near the horizon, and the vertical ice-prisms are exceptionally numerous, the parts of the halo of 22° which are at the same level as the sun are coloured spectra, sometimes dazzlingly bright, and they are called *Parhelia*, or, vulgarly, *Mock-Suns*. When the sun is *not* on the horizon, the paths of the rays through the vertical prisms are no longer in planes perpendicular to their edges. Here also there is a position of minimum deviation, but the deviation is greater than before, increasing with the obliquity of the rays. Also a ray, passing anyhow through a prism, makes equal angles with the edge (in this case vertical) before and after passing. This is evident, without calculation, from the principle of reversal. Hence, as the sun rises higher, the parhelia gradually separate outwards from the halo, still keeping, however, at the same apparent altitude as the sun.

If there be an excess of hexagonal prisms, or plates, with their axes horizontal, these also will produce parhelia, which will be situated on the halo above and below the sun, if the axes of the prisms are perpendicular to the line joining the sun and the spectator. But as they are as likely to lie in any other (horizontal) direction, there

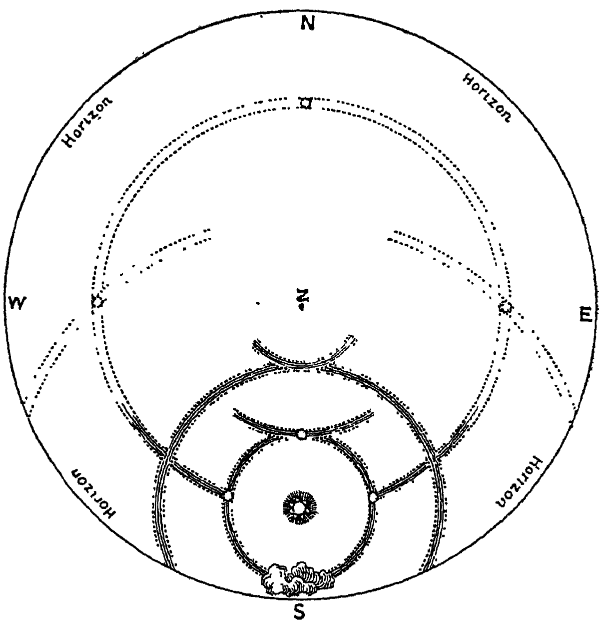

Diagram of Halos and Mock-Suns. (After Hevelius.)

will be a continuous series of parhelia, forming a new halo, which *touches* that of 22° externally above and below, and may even, in favourable circumstances (such as the requisite altitude of the sun, &c.), assume a complete quasi-elliptic form. This halo is brightest at its upper and lower portions, which are usually the only parts visible, and they are therefore commonly called the tangent-arcs to the halo of 22°.

Similar remarks apply to the halo of 46°, and the hexagonal pyramids, which sometimes terminate the ice-prisms, produce analogous results. The parhelia, also, are sometimes themselves bright enough to produce secondary halos; the reflection of the sun's rays from the surfaces of the crystals gives, from an excess of horizontal prisms, a colourless, vertical, great circle passing through the sun, and from an excess of vertical faces, a colourless, horizontal, small circle at the same altitude as the sun. All the features described, with the exception of the colourless vertical great circle, will be easily recognized in the accompanying diagram, which is reduced from a drawing by Hevelius of a remarkable series of halos and mock-suns seen by him at Danzig in 1661. There is, however, one feature in this figure, namely, the whitish, incomplete circle of about 90° radius surrounding the sun, which has been observed by others than Hevelius,

but is not yet explained. For full details on this very interesting subject see the remarkable memoir by Bravais (*Journal de l'École Polytechnique*, 1847), who studied the phenomena in high latitudes. The general explanation of the production of halos was suggested by Mariotte, but was first accurately given by Young.

Halos must not be confounded with *Coronæ*—those concentric rings which encircle the sun or moon when seen through a mist or cloud. Halos are red inside, coronæ outside. Halos have definite radii depending on the definite angles of ice-crystals; the size of the coronæ, whose radii are as 1 : 2 : 3, &c., depends on the size of the drops of water in a mist or cloud, being smaller as the drops are larger. Thus their diminution in radius shows that the drops are becoming larger, and implies approaching rain. They are due to diffraction, and can be explained only by the help of the undulatory theory.

(P. G. T.)

Halsbury, Hardinge Stanley Giffard, 1st Earl of (1825-——), Lord High Chancellor of England, son of Stanley Lees Giffard, LL.D., was born in London on 3rd September 1825. He was educated at Merton College, Oxford, where he took the degree of B.A. in 1852 and M.A. in 1855. Called to the bar at the Inner Temple in 1850, he joined the North Wales and Chester Circuit. Afterwards he had a large practice at the Central Criminal Court and the Middlesex Sessions, and he was for several years junior prosecuting counsel to the Treasury. He was engaged in most of the celebrated trials of his time, including the Overend and Gurney and the Tichborne cases. He became Queen's Counsel in 1865, and a bencher of the Inner Temple. Mr Giffard twice contested Cardiff in the Conservative interest, in 1868 and 1874, but he was still without a seat in the House of Commons when he was appointed Solicitor-General by Mr Disraeli in 1875 and received the honour of knighthood. In 1877 he succeeded in obtaining a seat, when he was returned for Launceston, which borough he continued to represent until his elevation to the peerage in 1885. He was then created Baron Halsbury and appointed Lord Chancellor, thus forming a remarkable exception to the rule that no criminal lawyer ever reaches the Woolsack. Lord Halsbury resumed the position in 1886, and again in 1895 and 1900, his tenure of the office, broken only by the brief Liberal ministries of 1886 and 1892–95, being longer than that of any Lord Chancellor since Lord Eldon. In 1898 he was created Earl of Halsbury and Viscount Tiverton. Among Conservative Lord Chancellors Lord Halsbury must always hold a high place, his grasp of legal principles and mastery in applying them being pre-eminent among the judges of his day.

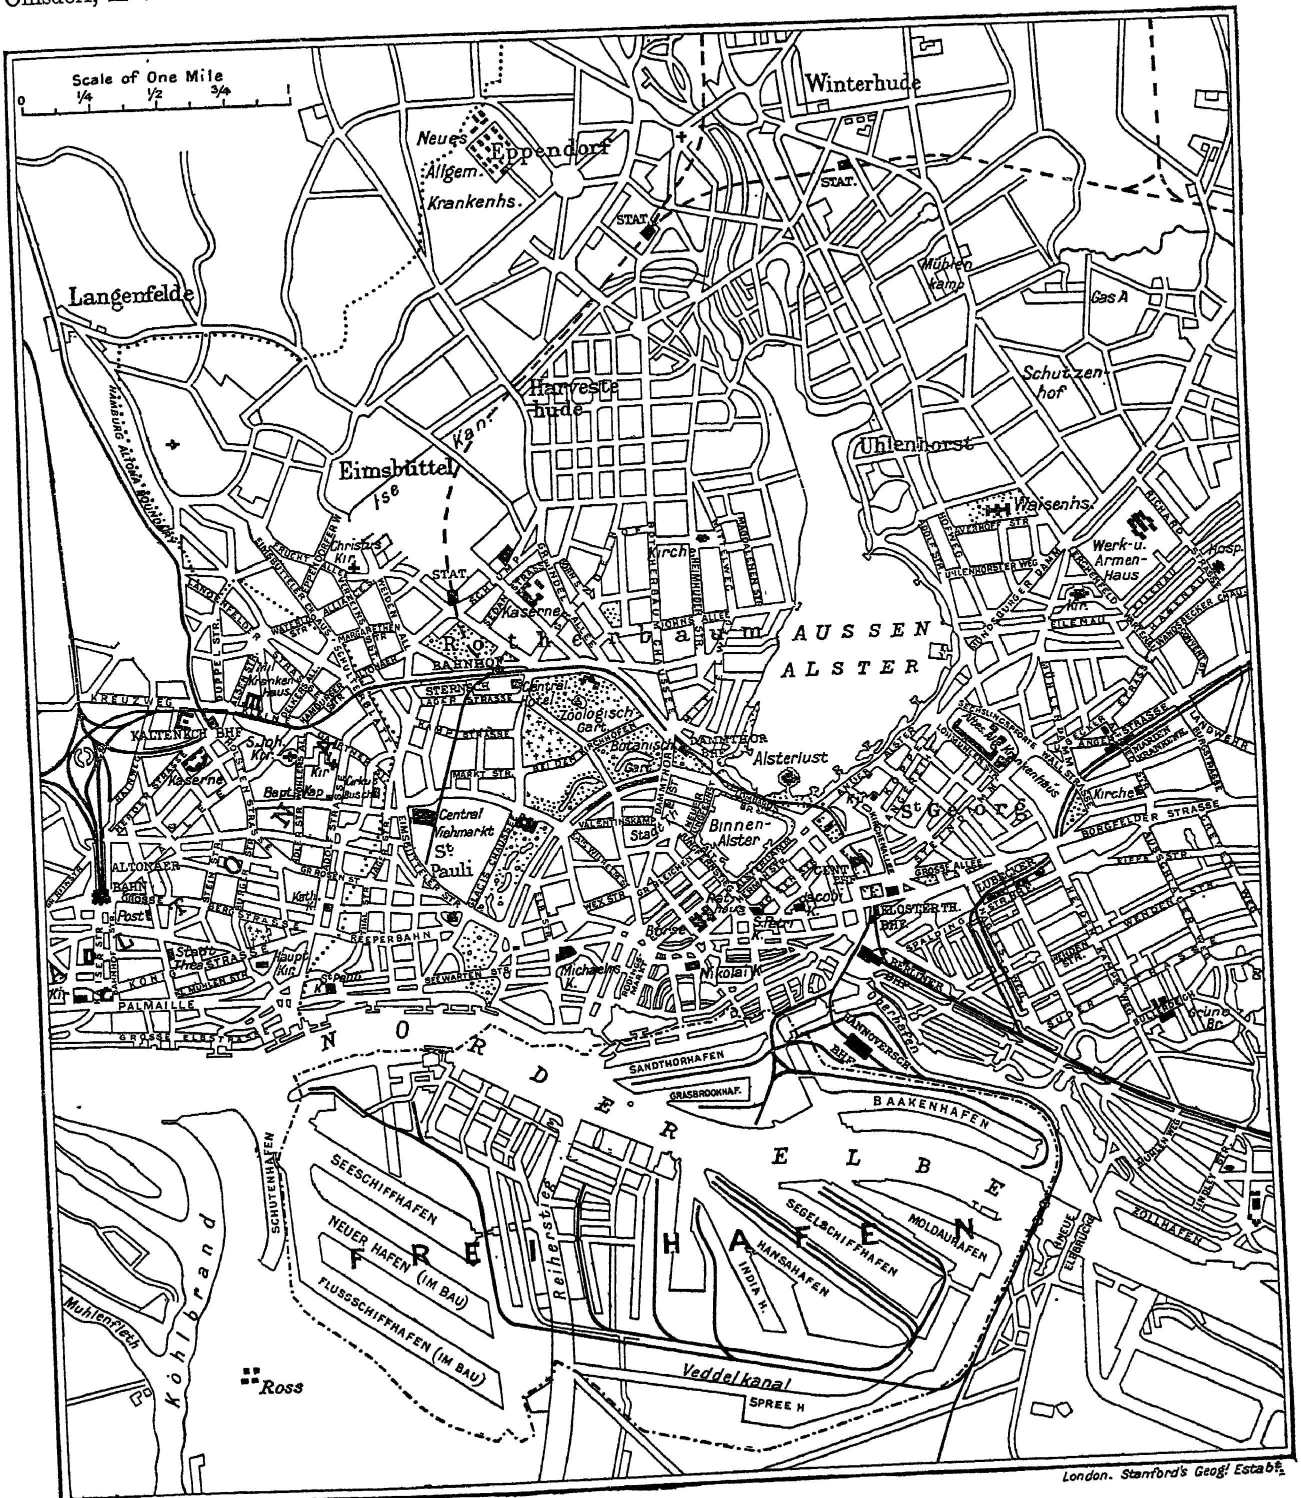
Halstead, a market-town in the Maldon parliamentary division of Essex, England, on the Colne, 14 miles north-west by west of Colchester by rail. A new post office, a cottage hospital, and a fever hospital have been erected, and there is a town hall. About 1200 hands are employed in the manufacture of silk and crape. The old civil parish of Halstead became divided under the Local Government Act, 1894, into two parishes, Halstead (urban) and Halstead (rural). Area of urban district, 636 acres. Population (1881), 5804; (1891), 6056; (1901), 6072. The urban district is coterminous with the civil parish of Halstead (urban). Population of the rural district of Halstead in 1901, 10,176.

Hamar, or Storehammer (Great Hamar), a town of Norway, county Hedemarken, on the east shore of Lake Mjösen, 78 miles by rail north of Christiania, on the railway to Trondhjem. The existing town was laid out in 1849, and made a bishop's see in 1864. Near the same site there stood an older town, which, together with a bishop's see, was founded in 1152 by the Englishman Nicholas Breakspeare (afterwards Pope Adrian IV.); but both town and cathedral were destroyed by the Swedes in 1567. A few scanty ruins of the latter still remain. Population (1900), 6003.

Hamburg, a seaport town of Germany, capital of the free state of Hamburg, situated on the right bank of the Elbe, 75 miles from the North Sea and 178 by rail west-north-west from Berlin, the largest and most important seaport on the continent of Europe, and (next after London and New York) the third largest port in the world. Probably there is no place which during the last thirty years of the 19th century grew at a faster rate commercially than Hamburg. Its commerce is, however, almost entirely of the nature of transit trade, for it is not only the chief distributing centre for the middle of Europe of the products of all other parts of the world, but it is also the chief outlet for German, Austrian, and even to some extent Russian (Polish) raw products and manufactures.

Public Buildings and Institutions.—The centre of the civic life of Hamburg is the new Rathhaus, a huge German Renaissance building, constructed of sandstone in 1886–97, and richly adorned with sculptures both outside and inside. It is the place of meeting of the civic council and of the senate, and affords accommodation for the town archives. Immediately adjoining it, and connected with it by a couple of wings, is the Börse (1839–41, enlarged 1880–84, and in part restored 1894); it shelters the commercial library of nearly 100,000 volumes. A little to the east of them is the Johanneum (1834), in which are preserved the town library of about 600,000 volumes and 5000 MSS., and the collection of Hamburg antiquities. In the courtyard is a statue (1885) of the Reformer Bugenhagen. In the Fischmarkt, immediately south of the Johanneum, a handsome fountain was erected in 1890. Directly west of the town hall is the new (rebuilt) Stadthaus, the chief police station of the town, with a bronze statue of the burgomaster Petersen (1898) in front of it. Several new public buildings have been erected along the circuit of the former walls. Near the west extremity, abutting upon the Elbe, the moat was filled in in 1894–97, and some good streets were built along the site, whilst the Kersten Miles Brücke, adorned with statues of four Hamburg heroes, was thrown across the Helgoland Allee. Farther north, along the line of the former town wall, stand the criminal law courts (1879–82, enlarged 1893) and the civil law courts (finished in 1901). Close to the latter will stand a new Supreme Court. Farther on are the chemical and the physical laboratories and the Hygienic Institute. Facing the Botanischer Garten a new central Post Office, in the Renaissance style, was built in 1887. At the west end of the Lombard Brücke (which divides the Aussen from the Binnen Alster) the municipality have erected a monument, designed by Schilling, to commemorate the war of 1870–71. A few streets south of that is a monument to Lessing (1881). The Kunst-halle (enlarged in 1885–86) faces the east end of Lombard Brücke. The new Naturhistorisches Museum, completed in 1891, stands a little distance farther south. Then to the east of it comes the Museum for Art and Industry, founded in 1878, now one of the most important institutions of the kind in Germany; there is a trades school connected with it. The Hansa fountain (65 feet high), erected in 1878, is close by. On the north-east side of the suburb of St Georg a botanical museum and laboratory have been established. There is

a new General Hospital at Eppendorf, outside the town on the north, built on the pavilion principle, and one of the finest structures of the kind in Europe; and at Ohlsdorf, in the same direction, a crematorium was built in 1891 in conjunction with the town cemeteries (370 acres). In 1899 a new central railway station was begun on the Glockengiesserwall between the Aussen Alster and the Frei Hafen. It only remains to mention



PLAN OF HAMBURG.

Hagenbeck's zoological garden, the schools of music and navigation, and the commercial school. In 1900 a high school for shipbuilding was founded, and in 1901 an institute for seamen's and tropical diseases, with a laboratory for their physiological study, was opened, and also the first public Free Library in the city. The river is spanned just above the Frei Hafen by a triple-arched railway bridge, 1339 feet long, made in 1868–73 and doubled in width in 1894. Some 270 yards higher up is an iron bridge (1888) for vehicles and foot passengers. The southern arm of the Elbe, on the south side of the island of Wilhelmsburg, is crossed by

another railway bridge of four arches and 2050 feet in length.

Harbour.—It was the accession of Hamburg to the German Customs Union in 1888 which gave such a vigorous impulse to her more recent commercial development. At the same time a portion of the port was set apart as a free harbour, altogether an area of 750 acres of water and 1750 acres of dry land. In anticipation of this event a gigantic system of docks, basins, and quays was constructed, at a total cost of some £7,000,000 (of which the imperial treasury contributed £2,000,000), between the confluence of the Alster and the railway bridge (1868–73), an entire quarter of the town inhabited by some 24,000 people being cleared away to make room for these accessories of a great port. On the north side of the Elbe there are the Sandthor basin (3380 feet long, 295 to 427 feet wide), in which British and Dutch steamboats and steamboats of the Sloman (Mediterranean) Line anchor. South of this lies the Grasbrook basin (quayage of 2100 feet, and 1693 feet alongside), which is used by French, Swedish, and transatlantic steamers. At the quay point between these two basins there are vast state granaries. On the outer (*i.e.*, river) side of the Grasbrook dock is the quay at which the emigrants for South America embark, and from which the mail boats for East Africa, the boats of the Woermann (West Africa) Line, and the Norwegian tourist boats depart. To the east of these two is the small Magdeburg basin, penetrating north, and the Baaken basin, penetrating east, *i.e.*, parallel to the river. The latter affords accommodation to the transatlantic steamers, including the emigrant ships of the Hamburg-America Line,[1] though their "ocean mail boats" generally load and unload at Brunshausen, 30 miles lower down the Elbe and on the opposite (left) bank, but from 1901 at Cuxhaven. On the south bank of the stream there follow in succession, going from east to west, the Moldau dock for river craft, the sailing vessel dock (3937 feet long, 459 to 886 feet wide, 26¼ feet deep), the Hansa dock, India dock, petroleum dock, several swimming and dry docks; and in the west of the free port area three other large docks, one of 77 acres for river craft, the others each 56 acres in extent, and one 23¾ feet deep, the other 26¼ feet deep, at low water, constructed in 1900–1. In 1897 Hamburg was provided with a huge floating dock, 558 feet long and 84 feet in maximum breadth, capable of holding a vessel of 17,500 tons and draught not exceeding 29 feet, so constructed and equipped that in time of need (war) it could be floated down to Cuxhaven. During the last 25 years of the 19th century the channel of the Elbe was greatly improved and deepened. During the last two years of the century some £360,000 was spent by Hamburg alone in regulating and correcting this lower course of the river. (See ELBE.)

Commerce and Shipping.—The details of the commercial development of the port are set forth in the subjoined tables.

As will be seen from Table I., it is with what may be termed the newer countries that the commerce has grown most rapidly; and this generalization is still further supported by the development of the trade with the South American states, West and East Africa, and the Far East. The imports from Great Britain more than doubled in annual value between 1851 and 1900; but the percentages which these totals bear to the entire sea-borne trade of Hamburg steadily decreased, *e.g.*, from 60 per cent. in 1851–60, and 64 per cent. in 1861–70, to 54 per cent. in 1871–80, to 40 per cent. in 1891–95, and to only 11 per cent. in 1900. Of the trade with older countries, there has been the greatest advance in the relations with Russia: in 1851–60 Hamburg imported less than £50,000 worth of Russian goods, but in 1900 the imports (by sea only) were valued at £4,460,500. The principal imports in the year 1898, and their values, were as follows:—Wool and woollens, £14,898,000; cereals, £11,931,400; sugar and molasses, £10,475,700; raw cotton and cottons, £8,706,200; coffee, £8,457,900; metals, £7,070,800; machinery, £6,098,100; skins and hides, £5,338,300; lard, butter, cheese, eggs, and milk, £4,666,200; flax, jute, and hemp, £4,421,300; tobacco, £4,287,700; iron, £4,101,750; chemicals, £3,814,500; gutta-percha, india-rubber, and gums, £2,787,900. In 1900 the imports were thus classified:—raw materials and partly manufactured goods, £61,677,400; foodstuffs, £35,137,000; textiles, £3,617,400; building materials and fuel, £3,446,600; and other industrial products, £7,925,600.

Table I. shows particulars of the average annual imports for the periods specified (bullion and coin not included):—

Imports.	1881-90.	1891-95	1900.[2]	Increase per cent. 1851-1900.
Total by sea . .	£52,288,800	£77,949,500	£111,804,000	601[3]
Total by rail and river . . .	45,103,000	58,090,000	..	723
Grand Total .	£97,391,800	£136,039,500	..	645
From Great Britain	£20,924,400	£19,573,200	£22,272,200	223
From Australia .	438,800	1,453,100	2,440,900	76,160
From British North America . .	71,400	272,000	..	45,300
From Cape Colony .	215,300	412,500	252,400	1,053
From British India	1,174,600	5,825,800	8,219,300	4,406
From the United States . . .	6,075,500	9,905,200	23,700,000	3,003

[2] In 1899 the imports by rail and river amounted to £66,935,000, and the imports by sea to £99,225,000, or altogether to £166,160,000.
[3] These are calculated to 1899.

Table II. shows the average annual value of the exports for the periods specified (bullion and coin excluded):—

Exports.	1881-90.	1891-95.	1900.	Increase per cent. 1851-1900.
Total by sea .	£49,070,700	£63,359,600	£88,776,000	751
Total by rail and river . .	40,293,000	56,405,500	..[4]	661
Grand Total .	£89,363,700	£119,765,100	..	705
To Great Britain .	No returns.	£19,351,400	£19,262,500	468

[4] In 1899 the exports by sea amounted to £80,315,000, and by rail and river to £70,500,000; or altogether to £150,815,000.

In 1900 the exports to the United States reached a value of £10,833,200; the exports to Brazil a value of £3,088,400; to Sweden and Norway, £6,184,200; to Russia, £3,608,500. The greater portion of the exports (53·5 per cent. of the whole) goes to the German states. The various items are almost the same, and at approximately the same amounts, as the imports.

Table III. shows the average number and aggregate tonnage of the vessels which entered the port annually, river craft being distinguished from ocean-going vessels, at the periods specified:—

		1851-60.	1881-90.	1891-95.	1899.[5]	Tonnage, Increase per cent. 1851-96.
By sea .	Vessels	4,649	7,015	8,928	13,312	
	Tonnage	756,099	3,870,047	5,954,214	7,765,950	1027
By river .	Vessels	4,383	10,783	13,967	17,598	..
	Tonnage	411,659	1,889,141	2,985,541	4,268,426	1036
Total	Vessels	9,032	17,798	22,895	30,905	..
	Tonnage	1,167,758	5,759,188	8,939,755	12,034,376	1035
From Gt. Britain	Vessels	2,050	2,891	3,227	3,868	..
	Tonnage	447,290	1,840,297	2,184,051	2,361,000	528

[5] Owing to the introduction of the new measurement system in 1895, the totals of the tonnage for the years since then are about 20 per cent. less than under the old system of measurement.

In 1861–70 38·4 per cent. of the vessels which arrived by sea and 53·8 per cent. of the tonnage flew the British flag, 45·7 per cent. of the vessels and 33·6 per cent. of the tonnage the German flag (of which 32·9 per cent. of the vessels belonged to Hamburg and 72·2 per cent. of the tonnage), whereas in 1899 26·1 per cent. of the

[1] This is the largest steamship company in the world. At the end of 1901 it possessed a fleet of 117 steamboats, with an aggregate of 602,948 tons, 92 per cent. of which was built within the preceding twelve years. In addition it owns a fleet of 25,453 tons of river steamboats. The company in 1900 owned 80 per cent. of the total steam tonnage belonging to Hamburg, and 49 per cent. of the total steam tonnage of all Germany. In 1900 they launched the *Deutschland*, of 16,000 net tonnage and 35,000 horse-power, with estimated speed of 23 knots.

vessels which arrived by sea came under the British flag and 38·8 per cent. of the tonnage (29 and 30 respectively in 1900), as compared with 57·1 per cent. of vessels under the German flag and 50·2 per cent. tonnage.

Table IV. shows the average annual number of vessels, and their total tonnage, belonging to the mercantile fleet of Hamburg for the periods specified :—

	1881–90.	1891–95.	1900.	Increase per cent 1851–1901.
Sea-going vessels	504	626	792	178
Tonnage . .	359,697	621,482	998,854	836

Of the 792 vessels quoted for the year 1900, 486 were steamships and 307 sailing vessels. To the sea-going vessels must be added 4700 river boats, aggregating a total of 332,704 tons in 1898 ; also 157 fishing vessels of 4956 tons, of which only 8 of 264 tons were propelled by steam.

Emigration.—Hamburg is one of the principal Continental ports for the embarkation of emigrants. In 1881–90, on an average the number of emigrants was 90,889 a year (to the United States, 59,322). In 1900 the number was 87,153 (to the United States, 64,137). In the period 1891–1900 the total number of emigrants averaged 71,096 annually, of whom about 88 per cent. went to the United States. The emigrants are mostly Germans (30,514 in 1893, 11,582 in 1900), Russians (41,082 in 1900), and Austrian-Hungarians (28,862 in 1900).

Industries.—Of recent years Hamburg has also developed into an important industrial centre, more especially since the year 1882. The branches which are represented on the largest scale are shipbuilding (employing some 5000 men in 1897) ; iron and steel industries, *i.e.*, iron and copper foundries, iron works, rolling mills, machinery factories, tin works, lead works, zinc pipe factories, nail factories, tool factories, electrical plant works, &c. ; chemical factories and factories for explosives, employing about 4000 workpeople (1300 in 1887) ; jute mills, employing about 3000 hands ; a wool-carding factory, with over 1300 hands ; cotton and woollen spinning mills ; indiarubber goods factories (4000 hands) ; factories for finer leather goods, with about 2000 hands ; sawmills, joinery works, factories for furniture, boxes, &c , and cooperages ; tobacco and cigars (some 3000 hands) ; printing works, with over 2000 workpeople ; factories for ready-made clothing ; breweries and distilleries in great number ; flour mills, steam bakeries, chocolate, sugar, pork-packing, ice, margarine, and other factories connected with the supplying of provisions. Altogether more than 42,400 persons above 16 years of age were employed in industrial establishments in 1899.

Banking, as might be expected in a city of the commercial magnitude of Hamburg, is carried on on a very extensive scale. Table V. supplies particulars with regard to the five principal banks for the year 1898 :—

	Hamburg Branch of Imperial Bank.	N. German Bank.	Union Bank.	Commercial and Discount Bank.	German Bank—Hamburg Branch.
Capital . .	£7,500,000 (head bank in 1901)	£2,000,000	£1,500,000	£2,500,000	£7,500,000 (head bank)
Turnover for year	764,414,900	832,760,850	516,881,500	312,669,200	637,950,300
Reserve .	..	33,000	136,500	346,500	2,322,900 (head bank)
Advances upon security .	6,262,000	3,426,300	2,065,600	..	1,775,250
Discount and bill business	45,170,400	23,732,000	18,614,900	16,444,100	49,847,200

Population.—Including the suburbs (of which there are fifteen, and which were definitely incorporated with the city in 1894), the population of Hamburg amounted to 471,427 in 1885, to 569,260 in 1890, to 625,552 in 1895, and to 705,738 in 1900. The birth-rate was 34·3 per 1000 in 1899 and 24·1 per 1000 in 1897. The marriage-rate was 9·5 and 8·96 per 1000 in the same two years respectively. Since 1892, the year in which cholera visited Hamburg so fatally, great improvements have taken place in the sanitary arrangements of the city, as well as in the regulations for the water-supply. As a consequence the death-rate shows an excellent improvement, as the following table manifests :—

	1887–91. Average.	1892.	1893.	1894.	1895.	1896.	1897.	1898 and 1899.
Death-rate per 1000 inhabitants	23·8	39·3	20·1	17·9	18·9	17·5	16·89	17·3

In the year 1895 39 per cent. of the entire population were engaged in occupations on their own behalf, dependants and servants not being counted, or 243,929 persons (of whom 50,307 were women), out of a total of 606,788 employed, whilst the number of dependants was 307,985, and of domestic servants 27,434. The class first named, namely, those working on their own behalf, increased between 1882 and 1895 from 38·1 to 40·2 per cent. of the population engaged in all occupations, whereas the class of domestic servants decreased from 6 to 4·5 per cent. Of the first-named class, again, 38·2 per cent. were engaged in commerce and its ministrant branches in 1882 and 39·9 per cent. in 1895, whilst 44 per cent. in 1882 and 40·6 per cent. in 1895 were occupied in industrial pursuits. As some evidence of the general condition of prosperity which prevails, it may be mentioned that of those who were liable to pay income-tax in 1894, 26·6 per cent. enjoyed incomes ranging between £30 and £40 per annum, 49·8 per cent. incomes between £40 and £100, 19·6 per cent. incomes between £100 and £500, 3 6 per cent. incomes between £500 and £1000, and 0·4 per cent. incomes above £2500.

THE FREE STATE OF HAMBURG.—A modification of the constitution came into force in 1879, by which the House of Burgesses was reduced from 196 to 160 members, of whom one-half are elected by the direct votes of all tax-paying citizens, 40 by the owners of house property, and 40 by the members of the guilds, corporations, and courts of justice. A committee of this house, numbering 20 members, is charged with the duty of watching the action of the senate and preserving the integrity of the constitution. In 1900 the state revenue was £4,489,200 and the expenditure £4,373,650. The state contribution to the revenues of the empire was fixed in 1900 at £343,286, and in 1900 the state debt amounted to £18,776,300. The population increased from 453,869 in 1880 to 518,620 in 1885, to 622,530 in 1890, to 681,632 in 1895, and to 768,349 in 1900. The population of the country districts (exclusive of the city of Hamburg) was 62,611 in 1900. In 1895 633,949 of the inhabitants belonged to the Evangelical Lutheran Church, 24,518 were Roman Catholics, and 17,308 were Jews. Of the total population, about 16,200 were engaged in agricultural pursuits, the crops raised being principally vegetables and fruit, potatoes, hay, oats, rye, and wheat. The live stock in 1897 numbered 17,141 horses, 13,949 cattle, 16,602 pigs, and only 2727 sheep. The other industries of importance are sulphuric acid works (25,323 tons of sulphuric acid, valued at £42,540, in 1897), iron foundries (7345 tons, valued at £712,290), sugar refineries, breweries, and distilleries. Apart from the city of Hamburg, the chief centres of population are the town of Bergedorf and the commune of Cuxhaven (6208).

(J. T. BE)

Hameln, a town of Prussia, province of Hanover, 33 miles S.W. of Hanover by rail and on the river Weser. In 1875 a monument was erected to commemorate the legend of the "Pied Piper." Population (1885), 11,830 ; (1895), 16,508 ; (1900), 18,965.

Hamerling, Robert (1830–1889), Austrian poet, was born at Kirchberg am Walde in Upper Austria, on the 24th of March 1830, of humble parentage. He early displayed a genius for poetry, and his youthful attempts at drama, *Christopher Colombus* and *Märtyrer*, excited the interest and admiration of some influential persons. Owing to their assistance young Hamerling

was enabled to pass through a school course at the Gymnasium at Vienna. Proceeding to the university, he entered the Academic Legion, and took part in 1848 in the defence of Vienna, which was being besieged by Windischgratz; as a consequence of this action he was obliged to hide for a long time to escape arrest. He diligently pursued his studies in natural science and philosophy, and in 1855 was appointed teacher at the Gymnasium at Trieste. For many years he battled with ill-health, and in 1866 retired on a pension, which in acknowledgment of his literary labours was increased by the Government to a sum which enabled him to live without care until his death at Graz, where he had made his home, on the 13th of July 1889. Among his poetic productions, *Ahasver im Rom* (1866), his *chef d'œuvre*, shows the author's brilliant talent for description. Hamerling was one of the most remarkable of the poets of the modern German school; his imagination was rich and his poems full of natural grace. Among his other productions may be mentioned *Venus im Exil* (1858), *Der König von Sion* (1868), *Die Sieben Tod-Sünden*, *Blätter im Winde*, *Homunculus*, *Amor und Psyche*, and a novel, *Aspasia*, which gives a finely-drawn description of the Periclean age.

Hamerton, Philip Gilbert (1834–1894), English artist and author, was born at Laneside, near Shaw, close to Oldham, 10th September 1834. His mother died at his birth, and having lost his father ten years afterwards, he was educated privately under the direction of his guardians. His first literary attempt, a volume of poems, proving unsuccessful, he devoted himself for a time entirely to landscape painting, encamping out of doors in the Highlands, where he eventually rented the island of Innistrynych, upon which he settled with his wife, a French lady, in 1858. Discovering after a time that his qualifications were rather those of an art critic than of a painter he removed to the neighbourhood of his wife's relatives in France, where he produced his *Painter's Camp in the Highlands* (1863), which obtained a great success and prepared the way for his standard work on *Etching and Etchers* (1866). In the following year he published a book, entitled *Contemporary French Painters*, and in 1868 a continuation, *Painting in France after the Decline of Classicism.* He had meanwhile become art critic to the *Saturday Review*, a position which, from the burden it laid upon him of frequent visits to England, he did not long retain. He proceeded (1870) to establish an art journal of his own, *The Portfolio*, a monthly periodical, each number of which consisted of a monograph upon some artist or group of artists, frequently written and always edited by him. The discontinuance of his active work as a painter gave him time for more general literary composition, and he successively produced *The Intellectual Life* (1873), perhaps the best known and most valuable of his writings; *Round My House* (1876), notes on French society by a resident; and *Modern Frenchmen* (1879), admirable short biographies. He also wrote two novels, *Wenderholme* (1870) and *Marmorne* (1878). In 1884 *Human Intercourse*, another valuable volume of essays, was published, and shortly afterwards Hamerton began to write his autobiography, which he brought down to 1858. In 1882 he issued a finely illustrated work on the technique of the great masters of various arts, under the title of *The Graphic Arts*, and three years later another splendidly illustrated volume, *Landscape*, which traces the influence of landscape upon the mind of man. His last books were: *Portfolio Papers* (1889) and *French and English* (1889). In 1891 he removed to the neighbourhood of Paris, and died suddenly on 4th November 1894, occupied to the last with his labours on *The Portfolio* and other writings on art. In 1896 was published *Philip Gilbert Hamerton: an Autobiography*, 1834–58; and a *Memoir by his Wife*, 1858–94.

Hamilton, a police (extended 1878) and parliamentary burgh (Falkirk group) of Lanarkshire, Scotland, 10¾ miles south-east of Glasgow by road, with five stations on two railway systems. The surrounding coalfield is the richest in Scotland, and there is a considerable manufacture of cotton, lace, iron-work, and carriages. The park adjoining the seat of the dukes of Hamilton contains a racecourse, and the herd of aboriginal white cattle in Cadzow Chase was in 1901 the only one still extant in Scotland. The town is the depot of the 26th and 71st regimental districts. Various public halls have been erected, and there is a hospital and a fever hospital. A Free church was built in 1882 and a United Presbyterian in 1884 (both now United Free). The academy, with an average attendance in 1898–99 of 559, is the principal secondary school in the middle ward of the county. Population (1881), 18,517; (1901), 32,775.

Hamilton, a city of Ontario, Canada, at the western extremity of Lake Ontario. It is an important centre on the Grand Trunk, Canadian Pacific, and other railways, whilst an extensive system of electric railways connects the different parts of the city with one another and with the adjacent localities. It has three daily newspapers, an efficient police force and fire brigade, and is lighted by electricity and gas. As an industrial centre it has been called the Birmingham of Canada, containing iron-smelting works, rolling mills, cotton factories, stove, zinc-refining, agricultural implement, bridge, wire, screw and steel works, and pork-packing, tobacco, and canning factories. The extensive water-power at De Cew Falls, 32 miles distant, has been utilized for the generation of electricity, which is supplied for manufacturing purposes. Hamilton is represented in the Dominion Parliament by two members, and by the same number in the Ontario legislature; its local affairs are administered by a mayor and twenty-one aldermen. The total shipping for 1899–1900 was 1850 vessels, with a tonnage of 412,624; exports were valued at $1,808,200, imports at $6,891,149. Area of city in 1901, 3990 acres; total assessment, $29,163,050. Population (1881), 35,961; (1891), 48,980; (1901), 52,550.

Hamilton, capital of Butler county, Ohio, U.S.A., in 39° 23′ N. lat. and 84° 25′ W. long., on the Great Miami, 25 miles north of Cincinnati, at an altitude of 591 feet. It is on the Cincinnati, Hamilton, and Dayton, and the Pittsburg, Cincinnati, Chicago, and St Louis railways, and on the Miami and Erie canal. It has an abundant water-power in the river and canal, which is utilized in varied manufactures. Population (1880), 11,122; (1890), 17,565; (1900), 23,914, of whom 2949 were foreign-born and 347 were negroes.

Hamirpur, a town and district of British India, in the Allahabad division of the North-West Provinces. The town is on a tongue of land at the confluence of the Betwa and the Jumna, 110 miles N.W. of Allahabad. Population about 9000. The District has an area of 2289 square miles. It had a population in 1881 of 507,337, and in 1891 of 513,720, giving an average density of 224 persons per square mile. The land revenue and rates were Rs.8,85,367, the incidence of assessment being R.0–11–7 per acre; the cultivated area was 600,918 acres, of which 21,633 were irrigated; the number of police was 1688; the number of vernacular schools in 1896–97 was 72, with 2707 pupils; the registered death-rate was 65·18 per 1000. In 1901 the population was 458,645,

showing a decrease of 11 per cent., due to the famine of 1896–97. The south of the district is traversed by the line of the Indian Midland Railway from Banda to Jhansi. The largest place is Rath (13,000).

Hamley, Sir Edward Bruce (1824–1893), British soldier and military writer, youngest son of Vice-Admiral William Hamley, was born on 27th April 1824 at Bodmin, Cornwall, and entered the Royal Artillery as second lieutenant in 1843. He was promoted to be captain in 1850, and in 1851 went to Gibraltar, where he commenced his literary career by contributing articles to magazines. He served throughout the Crimean campaign as aide-de-camp to Sir Richard Dacres, commanding the artillery, taking part in all the operations (medal and four clasps, 5th class of Legion of Honour and Medjidie, Sardinian and Turkish medals, brevet-majority and lieutenant-colonelcy, and C.B.). During the war he contributed to *Blackwood's Magazine* an admirable account of the progress of the campaign, which was afterwards republished separately. The combination in Hamley of literary and military ability secured for him in 1859 the professorship of Military History at the New Staff College at Sandhurst, from which, in 1866, he went to the Council of Military Education, returning in 1870 to the Staff College as commandant. From 1879 to 1881 he was British Commissioner successively for the delimitation of the frontiers of Turkey and Bulgaria, Turkey in Asia and Russia, and Turkey and Greece (K.C.M.G., 2nd class of Medjidie). Promoted colonel in 1863, he became a lieutenant-general in 1882, when he commanded the 2nd division of the expedition to Egypt under Lord Wolseley, and led his troops to the successful storm of Tel-el-Kebir (medal and clasp and star, 2nd class of Osmanieh, thanks of Parliament, and K.C.B.). Hamley considered that his services in Egypt had been insufficiently recognized in Lord Wolseley's despatches, and expressed his indignation freely. As, however, both he and the other divisional commander, Sir George H. S. Willis, were mentioned in the final despatch and were suitably rewarded, it cannot be supposed that there was any intention to belittle their services. From 1885 until his death on 12th August 1893 he represented Birkenhead in Parliament in the Conservative interest. Hamley was a clever and versatile writer. His principal work, *The Operations of War*, published in 1867, became a text-book of military instruction. He published some pamphlets on national defence, was a frequent contributor to magazines, and the author of several novels, of which perhaps the best known is *Lady Lee's Widowhood*. (R. H. V.)

Hamlin, Hannibal (1809–1891), Vice-President of the United States (1861–65), was born in Paris, Maine, on the 27th of August 1809. He studied law, and was admitted to the bar in 1833. Entering politics as a Democrat, he was a member of the Maine legislature 1836–40. In 1843 he was elected to Congress, where he served in the House of Representatives till 1847, and then in the Senate, with a short interval, till 1861. He opposed the extension of slavery, was concerned in the origination of the Wilmot Proviso, and in 1856, because of the repeal of the Missouri Compromise, he formally abandoned his old party and joined the Republicans. Nominated and elected with Lincoln in 1861, he was set aside at the end of his term through the preference of the party leaders for a Southern Democrat. After two terms more in the Senate (1869–81) and a brief service as minister to Spain (1881–83), he retired from public life in 1883, and died at Bangor (Me.), 4th July 1891.

Hamm, a town of Prussia, province of Westphalia, on the Lippe, 19 miles by rail north-east of Dortmund. It has important iron industries, wire and machinery factories, production of chemicals, varnishes, &c., saw-mills, and distilleries. Population (1885), 22,520; (1900), 31,369.

Hamme, a town of Belgium, in the province of East Flanders, 5 miles north of Termonde by rail. Its manufactures include rope, lace, linen, and oil. There are also boat-building workshops. Population (communal) (1899), 13,593.

Hammerfest, a seaport town of Norway, county Finmarken, in 70° 39′ 15″ N., 23° 39′ E. The principal street was rebuilt after a fire in 1890, and the town is lighted by the electric light. As a rule the sun is visible from Hammerfest uninterruptedly from 13th May to 29th July, and is never seen from 20th November to 21st January. Population about 2200.

Hammersmith, a metropolitan borough in the county of London, on the north bank of the Thames, 3½ miles south-west of Hyde Park Corner. Hammersmith Bridge, designed by Tierney Clark (1824), was the earliest suspension bridge erected near London. The old bridge being found to be in an insecure condition, a new one from the designs of Sir Joseph Bazalgette was erected in 1884–87. The superstructure is carried by steel chains, which are passed over towers formed of a framing of wrought-iron enclosed in an ornamental cast-iron casing. Down to 1834 Hammersmith formed a portion of Fulham parish. The parish church of St Paul's was built as a chapel of ease to Fulham, and consecrated by Bishop Laud, 7th June 1631. In 1864 it was enlarged and restored. It was subsequently pulled down, and a new church on the old site was completed in 1890. The Godolphin School, founded in the 16th century under the will of William Godolphin, was remodelled as a grammar school, under the approval of the Court of Chancery in 1861. The new buildings were completed in 1862 from the designs of C. H. Cooke. St Paul's School was removed from St Paul's Churchyard to Hammersmith Road, West Kensington, near Addison Road station, in 1883. The Mercers' Company purchased 16 acres of land and erected new buildings from the designs of Mr Barnes Williams. The Mall facing the river still contains many fine houses, but the old mansions of other parts of Hammersmith have mostly been pulled down. The market gardens and farms have been built over, so that the population has largely increased at each decennial period. Population (1881), 71,939; (1901), 112,245.

Hammond, a city of Lake county, Indiana, U.S.A., 20 miles south-east of Chicago, at an altitude of 590 feet. It is traversed by no fewer than eight railways approaching Chicago from the east. It has a level site on Grand Calumet river, and contains iron and steel works, and slaughter and packing houses. Population (1880), 699; (1890), 5428; (1900), 12,376, of whom 3156 were foreign-born.

Hampshire, HANTS, or SOUTHAMPTON, a southern county of England, bounded (as regards its mainland portion) on the S. by the English Channel, on the W. by Dorset and Wilts, on the N. by Berks, and on the E. by Surrey and Sussex. The county also embraces the Isle of Wight in the English Channel.

Area and Population.—The area of the ancient and administrative county (including the Isle of Wight, with an area of 93,342 acres and a population in 1901 of 82,387), as given in the census returns of 1891, was 1,037,769 acres or 1622 square miles, with a population in 1881 of 593,465, and in 1891 of 690,097, of whom 337,546 were males and 352,551 females, the number of persons per square mile being 425, and of acres to a person 1·50. Excluding the Isle of Wight and the two county boroughs of Portsmouth and

Southampton, the area was 938,098 acres, with a population in 1891 of 386,849. In 1895 certain alterations were made in the area of the administrative county. The parish of Combe was transferred from Hampshire to Berkshire, and the parish of Dockenfield to Surrey, and to Hampshire were added from West Sussex the part of the parish of Bramshott in West Sussex, and from Wilts the parishes of Bramshaw, Martin, Melchet Park, Plaitford, South Damerham, Toyd Farm with Allenford, and the part of the parish of Whichbury in Wilts. The area of the registration county is 1,047,223 acres, with a population in 1891 of 666,250, of which 414,600 were urban and 251,650 rural. Within the registration area the increase of population between 1881 and 1891 was 16·08 per cent. The excess of births over deaths between 1881 and 1891 was 80,634, but this was exceeded by the increase in the resident population, which was 91,073. The population of the ancient county in 1901 was 798,756. The number of Scots in the county in 1891 was 7243, of Irish 11,848, and of foreigners 2954.

The following table gives the numbers of marriages, births, and deaths, with the number of illegitimate births:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	4209	17,882	10,674	405	390
1890	4578	17,982	10,590	369	337
1898	5591	19,126	11,374	439	393

Marriages in 1899, 5792; births, 19,000; deaths, 13,207.

The following table gives the marriage-, birth-, and death-rate per 1000 of the population, with the percentage of illegitimate births, for a series of years:—

	1870-79.	1880.	1880-89.	1890.	1888-97.	1899.
Marriage-rate	15·3	14·7	14·6	13·9	14·6	15·1
Birth-rate	32·6	31·5	30·3	27·3	27·3	25·9
Death-rate	18·5	18·6	17·1	16·1	16·0	15·4
Percentage of Illegitimate Births	4·6	4·4	5·3	4·8	4·1	4·4

Constitution and Government.—The ancient county, including the Isle of Wight, is divided into six parliamentary divisions; and it also includes the parliamentary boroughs of Portsmouth and Southampton, each returning two members, and of Christ Church and Winchester, each returning one. The administrative county includes eleven municipal boroughs: Andover (6509), Basingstoke (9793), Bournemouth (47,003), Christ Church (4204), Lymington (4165), Newport (10,911), Portsmouth (189,160), Romsey (4365), Ryde (11,042), Southampton (104,911), and Winchester (20,919). Bournemouth, Portsmouth, and Southampton are county boroughs; the following are the urban districts: Aldershot (30,974), Alton (5479), Cowes (8654), East Cowes (3180), East Leigh (9317), Fareham (8246), Farnborough (11,499), Gosport and Alverstoke (28,879), Havant (3839), Itchin (13,097), Petersfield (3265), Pokesdown (4930), St Helens (4645), Sandown (5006), Shanklin (4533), Ventnor (5866), Warblington (3639), and Winton (6719). The administrative county is in the Western circuit, and assizes are held at Winchester. The boroughs of Andover, Basingstoke, Lymington, Newport, Portsmouth, Romsey, Ryde, Southampton, and Winchester have separate commissions of the peace, and the boroughs of Andover, Portsmouth, Southampton, and Winchester have in addition separate courts of quarter sessions. The ancient county, which is almost entirely in the diocese of Winchester, has 396 entire ecclesiastical parishes and part of one other.

Education.—There is a day training college (Hartley College) at Southampton for both masters and mistresses. At Portsmouth is the Hants and Isle of Wight school and home for the blind. On 31st August 1898 there were in the county 520 elementary schools, of which 119 were board and 401 voluntary schools, the latter including 358 National Church of England schools, 3 Wesleyan, 19 Roman Catholic, and 21 "British and other." The average attendance at board schools was 48,763, at voluntary schools 57,789. The total school board receipts for the year ending 29th September 1899 were over £146,180. The income under the Agricultural Rates Act was over £1520.

Agriculture.—About seven-tenths of the total area of the county is under cultivation, and of this area about two-fifths is in permanent pasture. There are also about 87,000 acres in hill pasture, and over 125,000 acres under woods, much of it ancient forest. The acreage under corn crops has been steadily diminishing, the diminution being chiefly in the acreage under wheat, which has now an average acreage of only about 60,000. Turnips are grown on more than one-half of the green crop acreage. Over 2000 acres are under small fruit, and about 2000 under orchards. The following table gives the larger main divisions of the cultivated area at intervals from 1880:—

Year.	Total area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	708,144	238,720	129,610	114,689	192,855	29,228
1885	711,521	222,226	133,464	110,802	233,751	17,957
1890	775,023	213,314	118,742	109,621	247,882	21,716
1895	705,969	184,100	110,988	117,674	266,124	22,087
1900	712,969	188,208	108,483	113,120	284,103	14,482

Much attention is paid to the rearing of sheep and cattle, but while the numbers of sheep have diminished, cattle have increased, the increase being wholly in cows for dairy purposes, and chiefly for the supply of milk. The following table gives particulars regarding the principal live stock:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	28,761	66,943	36,335	512,796	56,727
1885	28,189	82,561	42,030	524,715	68,591
1890	28,150	76,887	41,757	443,658	77,837
1895	29,101	76,402	44,465	366,004	82,434
1900	27,726	86,666	48,402	378,951	83,302

Industries and Trade.—According to the report for 1898 of the chief inspector of factories, the total number of persons employed in factories and workshops in 1897 was 44,660, as compared with 44,010 in 1896; 29,307 were employed in non-textile factories, there being an increase between 1895 and 1896 of 9·5 per cent., and between 1896 and 1897 of 3·8. Of these, 14,048 were employed in the manufacture of machines, appliances, conveyances, and tools, many in the Portsmouth dockyards and the carriage works at Southampton; 3302 in clothing industries, 2976 in the manufacture of paper, &c., and 1750 in that of drink. Workshops employed 15,154 persons, 6098 being employed in clothing industries, 2291 in the manufacture of machines, &c., 1879 in food industries, and 1055 in the manufacture of furniture, &c. While the naval establishments of Portsmouth have undergone great development, Southampton has become one of the principal ports of the kingdom for ocean steamers, and Aldershot is now the great military training centre of the empire. In 1899, 224,272 tons of chalk were raised, 64,079 tons of clay, and 13,349 tons of gravel and sand. The amount of fish landed in 1899 was 10,931 cwt., valued at £9683. The value of shell-fish, in addition, was £22,517.

London, 1892.—*History of Hampshire* (Victoria History Series). vol. i. 1900. See also *The Climate of Hampshire* in *Climates of Great Britain*, vol. i. London, 1895; and various papers in *Hampshire Notes and Queries.* (T. F. H.)

Hampstead, a metropolitan and parliamentary borough in the county of London, on the southern slope and the summit of Hampstead Hill, 4 miles north-west of the City. Owing to its position on the side of a hill, Hampstead largely retained its rural character till quite recently, and many of the houses still possess their old-world appearance, but great changes have been made of late years. Some of the old-fashioned houses in Church Row have been pulled down and replaced by flats. A large number of new houses has also been built in various parts. The hill is the highest in the vicinity of London, being 443 feet above the level of the Thames, or 36 feet higher than the cross of St Paul's. A chapel at Hampstead, dedicated to the Virgin Mary, is mentioned in a deed of 1461, and this seems to have stood until 1745, when it was taken down and a new church built from the designs of Henry Flitcroft, which was dedicated to St John, and consecrated in 1747. The church was enlarged in 1844. It is a plain brick structure in the Italian style, with the altar at the west end. The tower is the only picturesque portion of the building. Hampstead Heath is one of

the finest open spaces in the neighbourhood of London, and consists of 240 acres. At one time its permanence was in jeopardy, but attempts were made as early as 1829 to save the Heath from the builder. In 1871 the struggle for the preservation of the Heath was brought to a satisfactory conclusion by the agreement of Sir Thomas Maryon Wilson and his son, Mr Spencer Wilson, to give up all the rights in the Heath of the Lord of the Manor of Hampstead for the sum of £45,000. An Act of Parliament was passed transferring the ownership to the Metropolitan Board of Works, now represented by the London County Council. Golders Hill, to the north-westward of the West Heath, now under the control of the London County Council, was until 1898 in the occupation of the late Sir Spencer Wells, Bart. It consists of a house and 36 acres of land. The estate was purchased for £38,500, to which amount the County Council contributed £12,000. Hampstead has long been a favourite place of residence for lawyers, artists, poets and other men of letters, and the number of great names associated with the place is very large. It is also remarkable for its charitable institutions, one of the most important being the North London Consumptive Hospital. The sub-manor of Belsize and the hamlet of Kilburn are included in the borough of Hampstead. Population (1881), 45,452; (1901), 81,942.

See CAROLINE A. WHITE. *Sweet Hampstead, its Associations.* London, 1901.—*Records of the Manor, Parish, and Borough of Hampstead*, edited by T. E. BAINES. London, 1890.

Hampton, a parish and town of England, on the Thames, 12 miles W.S.W. of Hyde Park Corner, in the Uxbridge parliamentary division of Middlesex; station on a branch of the London and South-Western Railway. Included in the parish is Hampton Court, the Home Park of which was thrown open to the public in 1893. Garrick, Sir Christopher Wren, and Sir Richard Steele were residents of Hampton. The area of the civil parish and urban district is 2036 acres. Population (1881), 4776; (1891), 5822; (1901), 6812. HAMPTON WICK is a parish and urban district on the Thames, about a mile to the east of Hampton Court. Area, 1315 acres. Population (1881), 2164; (1901), 2606.

Hampton, Wade (1818–1902), American general, was born on the 28th of March 1818 at Columbia, South Carolina. He graduated at South Carolina University, and was trained for the law. Though national in early leanings, he threw himself with energy into the Southern cause in 1861, raising a mixed command known as "Hampton's Legion," which he led at Bull Run. He rose from brigadier to lieutenant-general in the course of the Civil War, serving chiefly in Stuart's cavalry. When General Sherman advanced northwards from Savannah, and Columbia, S.C., was burned, Hampton's command formed the rearguard of the Confederate retreat. He was chosen in 1876 governor of his state, and installed after a memorable contest; he served in the United States Senate 1879–91, and was United States commissioner of railways in 1893. He died 10th April 1902.

Hanau, a town of Prussia, province of Hesse-Nassau, on the right bank of the Main, 14 miles by rail east of Frankfort. In 1896 a monument to Jakob and Wilhelm Grimm was unveiled. There is a royal academy of industrial art design. Population (1885), 24,377; (1900), 29,846.

Hancock, Winfield Scott (1824–1886), American general, was born, 14th February 1824, in the village of Montgomery Square, Montgomery county, Pa. He was educated in the public schools and at West Point, his career at the latter being creditable but not distinguished. On the 1st of July 1844 he was breveted, and on the 18th of June 1846 commissioned second lieutenant. He took part in the later movements under Scott against the city of Mexico, and was breveted first lieutenant for "gallant and meritorious conduct." After the Mexican war he served at various places in the West, in Florida, and elsewhere; was married in 1850 to Miss Almira Russell of St Louis; became first lieutenant in 1853, and assistant-quartermaster with rank of captain in 1855. The outbreak of the Civil War found him in California. At his own request he was ordered East, and on 23rd September 1861 was made brigadier-general of volunteers and assigned to command a brigade in the army of the Potomac. He took part in the Peninsula campaign, and the handling of his troops in the engagement at Williamsburg, 5th May 1862, was so brilliant that McClellan reported "Hancock was superb," an epithet always afterwards applied to him. At the battle of Antietam he was placed in command of the first division of the second corps, and on 30th November of the same year was promoted from captain to major and assistant-quartermaster in the regular army. In the disastrous battle of Fredericksburg, Hancock's division was on the right among the troops that were ordered to storm Marye Heights. Out of the 5006 men in his division 2013 fell, among them not less than 156 commissioned officers. At Chancellorsville his division received both on the 2nd and the 3rd of May the brunt of the attack of Lee's main army. Soon after the battle he was appointed commander of the second corps. The battle of Gettysburg began 1st July in the defeat of the left wing of the army of the Potomac under General Reynolds. About the middle of the afternoon Hancock arrived on the field with orders from Meade to assume command and to decide whether to continue the fight there or to fall back. He decided to stay, rallied the retreating troops, and held Cemetery Hill and Ridge until the arrival of the main body of the Federal army. During the second day's battle he commanded the left centre of the Union army, and after the fall of Sickles the left wing. In the third day's battle he commanded the left centre, upon which fell the full brunt of Longstreet's attack, the most famous charge in the whole war. Hancock's superb presence and power over men never shone more clearly than when, as the 150 guns of the Confederate army opened upon the left centre, he calmly rode along the front of his line to show his soldiers that he shared the dangers of the cannonade with them. His corps lost in the battle 4350 out of less than 10,000 fighting men. But it had captured twenty-seven Confederate battle flags and as many prisoners as it had men when the fighting ceased. Just as the Confederate troops reached the Union line Hancock was struck in the groin by a bullet, but continued in command until the repulse of the attack. The wound proved a severe one, so that some six months passed before he resumed command. In the battles of the year 1864 Hancock's part was as important and striking as in those of 1863. At the Wilderness he commanded, during the second day's fighting, half of the Union army; at Spottsylvania he had charge of the fierce but successful attack on the "salient"; at Cold Harbor his corps formed the left wing in the unsuccessful assault on the Confederate lines. In August he was promoted to brigadier-general in the regular army. In November, his old wound troubling him, he obtained a short leave of absence, expecting to return to his corps in the near future. He was, however, detailed to raise a new corps, and later was placed in charge of the "Middle Division." It was expected that he would move towards Lynchburg, as part of a combined movement against Lee's communications. But before he

could take the field Richmond had fallen and Lee had surrendered. It thus happened that Hancock, who for three years had been the most conspicuous single figure in the army of the Potomac, did not take part in the final triumph.

After the assassination of Lincoln, Hancock was placed in charge of Washington, and it was under his command that Booth's accomplices were tried and executed. In July 1866 he was appointed major-general. A little later he was placed in command of the department of the Missouri, and the year following assumed command of the fifth military division, comprising Louisiana and Texas. His policy, however, of discountenancing military trials and conciliating the late rebellious states did not meet with approval at Washington, and he was at his own request transferred. Hancock had all his life been a Democrat. His splendid war record and his personal popularity caused his name to be considered as a candidate for the Presidency as early as 1868, and in 1880 he was nominated for that office by the Democrats; but he did not prove a strong candidate, and was defeated by General Garfield, though by the small popular plurality of a few thousand votes. He died at Governor's Island, near New York, on 9th February 1886. Hancock was in many respects the ideal soldier of the Northern armies. His large frame and majestic carriage helped him to look every inch the soldier that he was. He was quick, energetic, and resourceful, reckless of his own safety, a strict disciplinarian, a painstaking and hard-working officer. It was on the field of battle, and when the fighting was fiercest, that his best qualities came to the front. He was a born commander of men, and it is doubtful if any other officer in the Northern army could get more fighting and more marching out of his men. Grant said of him, "Hancock stands the most conspicuous figure of all the general officers who did not exercise a separate command. He commanded a corps longer than any other, and his name was never mentioned as having committed in battle a blunder for which he was responsible." A biography of him has been written by General Francis A. Walker.

(F. H. H.)

Hangchow, the capital city of the province of Chekiang, at the head of Hangchow Bay, China, 110 miles south-west of Shanghai. It was declared open to foreign trade in 1896, in pursuance of the Japanese treaty of Shimonoseki. It is connected with Shanghai by inland canal, which is navigable for boats drawing up to four feet of water, and which might be greatly improved by dredging. The cities of Shanghai, Hangchow, and Soochow form the three points of a triangle, each being connected with the other by canal, and trade is now open by steam between all three under the inland navigation rules. These canals pass through the richest and most populous districts of China, and in particular lead into the great silk-producing districts. They have for many centuries been the highway of commerce, and afford a cheap and economical means of transport. Hangchow lies at the head of the large estuary of that name, which is, however, too shallow for navigation by steamers. The estuary or bay is funnel-shaped, and its configuration produces at spring tides a "bore" or tidal wave, which is perhaps unequalled in any other part of the world. The inflowing tide becoming more and more concentrated as it advances, and being checked at its foot by the friction of the downrush of the river, gradually assumes the formation of a wall of water, the upper part being raised higher and higher by the augmenting flood from behind. At its maximum the wave reaches a height of 15 to 20 feet, and rushes past with a roar like thunder and the speed of a railway train. The population of Hangchow is estimated at 500,000. It is the great seat of the silk-weaving industry, and is celebrated for the production of fans, "joss paper," drugs, lacquer, &c. The volume of trade passing through the customs in 1899 was 11,501,000 H. (Haikwan, or customs) taels, equal to £1,729,000, which, however, was only a small part of the total trade.

Hankow, a treaty port on the north bank, and 700 miles from the mouth, of the Yangtse, China. Within recent years it has made rapid advance in wealth and importance. The opening up of the upper waters of the Yangtse to steam navigation has made it a commercial *entrepôt* second only to Shanghai. It is the terminus of the Belgian railway now in course of construction between Peking and the Yangtse, being the northern half of the grand trunk line from Peking to Canton. The southern half has been contracted for by an Anglo-American syndicate. There is daily communication by regular lines of steamers with Shanghai, and smaller steamers ply on the upper section of the river between Hankow and Ichang. The principal article of export continues to be black tea, of which staple Hankow has always been the central market. The bulk of the leaf tea, however, now goes to Russia by direct steamers to Odessa instead of to London as formerly, and a large quantity goes overland *viâ* Tientsin and Siberia in the form of brick tea. The quantity of brick tea thus exported in 1898 was upwards of 60 million lb. The exports which come next in value are opium, wood-oil, hides, beans, cotton yarn, and raw silk. The population of Hankow, together with the city of Wuchang on the opposite bank, is estimated at 800,000, and the number of foreign residents is about 500. Large iron-works have been erected by the Chinese authorities at Hanyang, a couple of miles higher up the river, and at Wuchang there are two official cotton mills. The British concession, on which the business part of the foreign settlement is built, was obtained in 1861 by a lease in perpetuity from the Chinese authorities in favour of the Crown. Subleases for a term of years are granted by the Crown to private individuals; local control, including the policing of the settlement, is managed by a municipal council elected under regulations promulgated by the British minister in China, acting by authority of the Sovereign's Orders in Council. Foreigners, *i.e.*, non-British, are admitted to become lease-holders on their submitting to be bound by the municipal regulations. The concession, however, gives no territorial jurisdiction. All foreigners, of whatever nationality, are justiciable only before their own consular authorities by virtue of the extra-territorial clauses of their treaties with China. In 1895 a concession on similar terms to that under which the British is held was obtained by Germany, and this was followed by concessions to France and Russia. These three concessions all lie on the north bank of the river and immediately below the British. An extension of the British concession backwards was granted in 1898. The total trade in 1900 was valued at £13,248,100 (£6,582,050 being exports and £6,666,050 imports), as compared with a total of £17,183,400 in 1900 and £11,628,000 in 1880.

Hanley, a municipal (1857), county (1888), and parliamentary (1885) borough and market town of Staffordshire, England, often styled "the metropolis of the Potteries," 150 miles by rail north-north-west of London. The adjoining municipal borough of Burslem is included in the parliamentary borough, which returns one member. The schools include a higher-grade elementary and science school, built in 1894, and a school of art. Other buildings include the free library (1887); a technical and art museum, transferred to the corporation in 1891; and a

theatre, reconstructed in 1894. Hanley Park, opened in 1894, covers 80 acres. In 1891 there were 5815 males and 4588 females employed in the manufacture of earthenware, china, and porcelain, and 2305 persons in coal-mining. There is a daily newspaper. Area of municipal borough, 1768 acres; population (1881), 48,361; (1901), 61,524.

Hannen, James Hannen, 1st Baron (1821–1894), English judge, son of a London merchant, was born in 1821. He was educated at St Paul's School, and then proceeded to Heidelberg University, which was famous as a school of law. Called to the bar at the Middle Temple in 1848, he joined the Home Circuit. At this time he also wrote for the press, and supplied special reports for the *Morning Chronicle*. Though not eloquent in speech, he was clear, accurate, and painstaking, and soon advanced in his profession, passing many more brilliant competitors. He appeared for the claimant in the Shrewsbury peerage case; was principal agent for Great Britain on the mixed British and American Commission for the settlement of outstanding claims, 1853–55; and assisted in the prosecution of the Fenian prisoners at Manchester. In 1868 Hannen was appointed a judge of the Court of Queen's Bench. In many cases he took a strong position of his own, notably in that of "Farrar *v.* Close," which materially affected the legal status of trade unions and was regarded by unionists as a severe blow to their interests. Hannen became judge of the Probate and Divorce Court in 1872, and in 1875 he was appointed President of the Probate and Admiralty Division of the High Court of Justice. Here he showed himself a worthy successor to Cresswell and Penzance. Many important causes came before him, but he will chiefly be remembered for the manner in which he presided over the Parnell Special Commission. His influence pervaded the whole proceedings, and it is understood that he personally penned a large part of the voluminous report. Hannen's last public service was in connexion with the Bering Sea inquiry at Paris, when he acted as one of the British arbitrators. In January 1891 he was created a life peer and appointed a Lord of Appeal, but in that capacity he had few opportunities for displaying his powers, and he retired at the close of the session of 1893. He died in London, after a prolonged illness, on 29th March 1894.
(G. B. S.)

Hannibal, a city of Marion county, Missouri, U.S.A., in 39° 44′ N. lat. and 91° 23′ W. long., on the west bank of the Mississippi, at an altitude of 473 feet. The business part is in the level bottom lands of the river, while the residence portion spreads up the banks, which afford fine building sites. It has four railways—the Chicago, Burlington, and Quincy; the Missouri, Kansas, and Texas; the Wabash; and the St Louis and Hannibal. It has a large lumber trade, and manufactures of railway cars, machinery, and other iron and steel goods. Population (1880), 11,074; (1890), 12,857; (1900), 12,780, of whom 925 were foreign-born and 1836 were negroes.

Hannington, James (1847–1885), bishop of Eastern Equatorial Africa, was born at Hurstpierpoint, in Sussex, on the 3rd of September 1847. From earliest childhood he displayed a love of fun, adventure, and natural history. At school he made little progress, and left at the age of fifteen for his father's counting-house at Brighton. He had no head for office work, and much of his time was occupied in commanding a battery of volunteers and in charge of a steam-launch. At twenty-one he resolved to prepare for the ministry, and in 1868 entered St Mary's Hall, Oxford, and soon exercised a remarkable influence over his fellow-students. His studies, however, did not make much progress, and in 1870 he was advised to repair to the little village of Martinhoe, in Devonshire, for quiet reading, but distinguished himself more by his daring climbs after sea-gulls' eggs and his engineering skill in cutting a pathway along precipitous cliffs to some caves. In 1872 the death of his mother, whom he dearly loved, made a deep impression upon him, and after studying hard he took his B.A. degree, and in the following year was ordained deacon and placed in charge of the small country parish of Trentishoe. Here his spiritual life underwent a great change. After ministering at Hurstpierpoint, his thoughts were turned by the murder of two missionaries on the shores of Victoria Nyanza to mission work. Accordingly he offered himself to the Church Missionary Society, and sailed on 17th May 1882 at the head of a party of six for Zanzibar, and thence set out for Uganda; but, prostrated by fever and dysentery, he was obliged to return to England in 1883. On his recovery he was consecrated bishop of Eastern Equatorial Africa, and in 1885 started again for the scene of his mission, and occupied himself on his arrival at Freretown in visiting many stations in the neighbourhood. Then, filled with the idea of opening a new route to Uganda, he set out and reached a spot near Victoria Nyanza in safety. His arrival, however, roused the suspicion of the natives, and under King Mwanga's orders he was lodged in a filthy hut swarming with rats and vermin. After eight days his men were murdered, and on the 29th of October 1885 he himself was speared in both sides, his last words to the soldiers appointed to kill him being, "Go, tell Mwanga I have purchased the road to Uganda with my blood."
(G. F. M*.)

Hanoi, capital of Tongking, French Indo-China, on the right bank of the Song-Koi or Red River, 60 miles in a direct line from the sea. It is the ancient *Ke-Sho* ("great market"), and few towns have undergone greater changes. Between 1892 and 1895 M. de Lanessan, the then Governor-General, completely altered its appearance. The old Annamese town has almost entirely disappeared, giving place to a magnificent city possessing all the improvements and comforts of European civilization. The Annamese citadel has been razed, and the town now covers over 2470 acres. The population, formerly not exceeding 50,000, now comprises more than 100,000 Annamese, besides 1700 Chinese and 1000 Europeans, almost exclusively French. For several years, especially from 1881 to 1895, Hanoi was regarded as the capital of Indo-China. Wide streets have been opened up, boulevards, squares, and promenades laid out, and a theatre and new Government offices built. A system of drains has been constructed and is being extended; the town is lighted by electricity, and there is a good water-supply. A fine botanical and zoological garden has been laid out, and the Lanessan Hospital was opened in 1894. Important works (embankments and quays) were undertaken in 1894 along the Red River for a distance of 2½ miles, and a commercial port to which the largest vessels can ascend is under construction. On the completion of the great bridge across the Red River three railway lines will cross at Hanoi—the lines from Hanoi to Haiphong, from Hanoi to Yenbai *viâ* Sontai (about to be extended to Laokai), and from Hanoi to Ninhbinh, which is ultimately to be prolonged to Thanh-hoa and Hué. The approaching connexion between Haiphong and Phu-Lang-Thuong will place Hanoi in communication with the Chinese frontier as far as the Canton river. River and sea communication are secured to Hanoi by the Messageries Maritimes, which run in conjunction with boats between

Haiphong, Hong Kong, and Saigon. The Messageries Fluviales ply regularly between Haiphong, Hong Kong, and Pakhoi, and also up the Red River to Laokai. Horse-racing is much enjoyed, and the town is at all times very animated. The course is 1420 yards long. Hanoi has a chamber of commerce, the president of which is entitled to a seat on the Superior Council of Indo-China. It has also a court of appeal, a tribunal of general commerce, and a civil tribunal of the first order. The great Indo-China Exhibition of 1902 was held in buildings specially erected on the race-course. (J. M. A. DE L.)

Hanotaux, Albert Auguste Gabriel (1853——), French statesman and historian, was born at Beaurevoir, in the department of Aisne, France, on the 19th November 1853. After successful studies at the École des Chartes, which made him an expert in historical research, he obtained a connexion with journalism. An article in the *République Française* procured him the notice of Gambetta, who brought him into the Ministry of Foreign Affairs, where, but for one brief excursion into parliamentary life, he continued until 1894, filling successively several important posts, and obtaining so much distinction that, with scarcely any political claim excepting his eminence as a civil servant, he was raised to the post of Minister on M. Dupuy's accession to power in May of that year. With one brief interruption, M. Hanotaux retained his position amid changing Ministries, until the resignation of the Méline Cabinet in June 1898. After his retirement M. Hanotaux devoted himself chiefly to literature. His *Histoire de Richelieu* (1893–96) made his reputation as a historian, and he was elected a member of the French Academy in 1897.

Hanover, a province of Prussia, with an area of 14,869 square miles and population of 2,590,939 (1900). The mines in 1898 gave an output of 529,925 tons of coal, valued at £221,000, and 90,643 tons of lignite, valued at £14,000; 730,045 tons of iron ore, valued at £138,700; 17,197 tons of zinc, valued at £87,800; 48,197 tons of lead, valued at £134,100; and 25,623 tons of copper, valued at £26,700: total value of minerals, £534,500. The output of the salt works and smelting furnaces consisted of 117,761 tons of salt, valued at £121,900; 7618 tons of Glauber salts, valued at £8500; 217,804 tons of iron, valued at £420,600; 11,008 tons of lead, valued at £139,350; 1,087,450 oz. of silver, valued at £163,500; and 27,954 tons of sulphuric acid, valued at £35,450: total value, £889,300. The produce of the iron-foundries amounted to 344,316 tons, estimated to be worth £2,331,000. In 1897 the live stock consisted of 1,314,762 pigs, 1,064,586 cattle, 971,669 sheep, and 234,604 horses. In 1899–1900 the sugar factories and refineries yielded 142,340 tons of sugar; the breweries, 36,630,000 gallons of beer; and the distilleries, 2,356,500 gallons (1897–98) of pure alcohol. In 1899 the mercantile marine numbered 843 sea-going vessels of 82,626 tons. The principal ports are Harburg, Emden, Papenburg, Leer, Geestemünde, Norderney, and Borkum. (See also GERMANY, PRUSSIA.)

Hanover, a town of Prussia, capital of the province of Hanover, 163 miles by rail west of Berlin, at the crossing of the Berlin–Cologne and Hamburg–Frankfort lines, and headquarters of the 10th German Army Corps. In the old town the more noteworthy recent buildings are the Kestner (archæological) Museum (1888), containing also the municipal library, the administrative offices (finished in 1878), the garrison church (1891–93), the new provincial museum (1900–1901), the Imperial Bank (1895–96) in the Italian Renaissance style, the industrial exhibition, industrial art school, large covered market (1890–92), and Gutenberg fountain (1890). The industrial art museum is now lodged in the house of Leibnitz. The new town hall was designed by Eggers. In the eastern quarters, which are half encircled by the Eilenriede woods and parks (1650 acres), there are the hall of the provincial estates, the Garden church (1887–91), a sandstone structure in the early Gothic style, with a tower 289 feet high and some good stained glass; the law courts (1880–82), the large convict prison (1865–75), Holy Trinity church (1881–83), a fine war monument (1884), and the veterinary high school. The old provincial museum (1853–54) in this part of the town now includes a variety of collections, such as natural history, ethnography. and modern paintings, besides the Cumberland gallery and the Guelph Museum. Here, too, is the zoological garden. On the north of the old town are the technical high school (1878–80), now in the Guelph Castle (1857–66); the riding and fencing school of the army; the Roman Catholic church of St Mary's, with a tower 302 feet high, and the grave of "His Little Excellency" Windthorst, for many years leader of the Ultramontane (Centre) party in the Imperial Diet; the Luther church (1898), the Apostles' church (1883), and Herrenhausen Castle, with its fine gardens, theatre, museum, orangery, &c., and the magnificent avenue (2200 yards long, 187 feet wide) which leads to it. Other public institutions comprise a high school for girls (1899), commercial school, blind asylum, cripples' home, military school, various seminaries for teachers, industrial art school, mint, &c. Hanover occupies a leading place amongst the industrial and commercial towns of the kingdom. Its staple industries are the manufacture of india-rubber and gutta-percha (1400 operatives), machinery (1100 men), iron-founding, and brewing. Besides these, hardware, linens, chemicals, tobacco, pianos, books, furniture, and various other articles are produced. The commerce is principally in the home manufactures, and in wine, chocolate, groceries, hides, horses, coal, wool, and cereals. In the industrial sister town of LINDEN (50,623), to the south-west, there are a new town hall, a church (1722), and the Alten Park. Population of Hanover (1885), 139,731; (1900), 235,666.

Hanover, a town of Grafton county, New Hampshire, U.S.A., on the east bank of the Connecticut, 55 miles north-west of Concord. It is connected by bridge with Norwich, and with the Boston and Maine Railway on the opposite bank of the river. It is the seat of Dartmouth College, a non-sectarian institution founded in 1796, and having in 1899, in all departments, 55 instructors and 694 students. Its endowment and the value of its plant amounted to two and a half million dollars, its library numbered 80,000 volumes, and its income for the year was $103,000. Population (1880), 2147; (1890), 1817; (1900), 1884.

Hanover, a borough of York county, Pennsylvania, U.S.A., at the intersection of a line of the Pennsylvania Railway with the Western Maryland Railway. Population (1890), 3746; (1900), 5302, of whom 133 were foreign-born.

Hansi, a town of British India, in the Hissar district of the Punjab, on a branch of the Western Jumna canal, with a station on the Rewari–Ferozepore Railway, 16 miles east of Hissar by rail. The population in 1881 was 12,656, in 1891 it was 15,190; the municipal income in 1897–98 was Rs.18,320. It is the ancient capital of the tract called Hariana, and was the headquarters of the Irish adventurer George Thomas at the end of the 18th century; from 1802 to 1857 it was a British cantonment, and the scene of a murderous outbreak during the Mutiny.

It is still surrounded by a high brick wall, with a dismantled fortress, and is the centre of local trade, with four factories for ginning and pressing cotton. There is an annual horse fair, and a municipal school.

Hanthawaddy, a district in the Pegu division of Lower Burma, the home district of Rangoon, from which the town was detached to make a separate district in 1880. It has an area of 3023 square miles, with a population in 1891 of 396,887, living in 1313 villages, and paying in 1898–99 a revenue of Rs.31,99,729. The population was made up of 371,308 Buddhists and Jains, 15,032 Hindus, 6236 Mahommedans, and 4311 Christians, many of whom were Karens. In 1901 the population was 484,847. The total area is 1,934,720 acres, of which, in 1898–99, 1,027,027 acres were cultivated, 167,723 were cultivable, 31,155 acres were lying current fallow, and 489,030 acres were not available for cultivation, while 219,785 acres were under forests. The rainfall in 1898–99, taken at Hmawbi, was 105·8 inches. The headquarters of the district are in Rangoon, which is also the sub-divisional headquarters. The second subdivision has its headquarters at Insein, where there are large railway works. There are nearly 200 schools in the district, with about 7000 pupils. Cultivation is almost wholly confined to rice, but there are many vegetable and fruit gardens.

Hanwell, a parish of England, on the Brent, 10 miles west of St Paul's, London, and in the Brentford parliamentary division of Middlesex; station on the Great Western Railway. St Mary's, the parish church, was built in 1841, and St Mark's in 1883. In the parish there are also a Catholic chapel (1864) and Baptist and Methodist chapels. In the neighbouring parish of Norwood is the Hanwell lunatic asylum of the county of London. Since its erection in 1831 it has been much extended, and can now accommodate over 2500 inmates. Its chapel was built in 1880. In Hanwell a Roman Catholic convalescent home was erected in 1865. Area of urban district, 1067 acres. Population (1881), 5178; (1901), 10,437.

Haparanda, a small town of Sweden, on the right bank of the Torneå, 1½ miles from its issue into the north extremity of the Gulf of Bothnia, immediately opposite to the Finnish town of Torneå, though, owing to the river having shifted its course, both towns stood in 1899 on the Swedish side of the stream. It has an important meteorological station; annual mean temperature, 32° Fahr.; February, 10·5°; July, 58·8°. Rainfall, 16·5 inches annually. Sea-going vessels load and unload at Salmis, 7 miles distant. Population (1880), 1039; (1900), 1568.

Harburg, a seaport town of Prussia, province of Hanover, 6 miles by rail south of Hamburg. A new bridge has been built (1899) across the south arm of the Elbe, on which Harburg stands, thus connecting it by means of the island of Wilhelmsburg with Hamburg on the north arm of the river. The port is accessible to vessels drawing 18 feet and measuring 4500 tons. Owing to its geographical position and cheap storage, Harburg is a distributing centre of not a little importance, despite its proximity to Hamburg. It is the chief mart in the empire for palm oil and resin; and in 1901 the Prussian Government contemplated converting it into a free port, and enlarging it relatively on the lines of Hamburg. The shipping entering has decreased from 636 vessels of 77,676 tons in 1888 to 428 vessels of 75,746 tons in 1899; in addition to which there are inland (river) entries of approximately 13,090 vessels of nearly three-quarters of a million tons. The leading industries are the crushing of palm kernels and linseed, and the manufacture of india-rubber, phosphates, starch, nitrate, and jute. Population (1885), 26,320; (1900), 49,155, the area of the town having been increased since 1895.

Harcourt, Sir William George Granville Venables Vernon (1827– ——), English statesman, second son of William Vernon Harcourt, of Nuneham Park, Oxford, was born 14th October 1827. He was educated at Trinity College, Cambridge, graduating with first-class honours in the classical tripos in 1851. He was called to the bar at the Inner Temple in 1854, became a Q.C. in 1866, and was appointed Whewell professor of international law, Cambridge, 1869. It was in these years that he contributed largely to journalism and wrote letters to *The Times* over the signature of "Historicus," which were published in book form in 1863. He entered Parliament as Liberal member for Oxford, and sat from 1868 to 1880, when, upon seeking re-election after acceptance of office, he was defeated by Mr Hall. A seat was, however, found for him at Derby, by the voluntary retirement of Mr Plimsoll, and he continued to represent that constituency until 1895, when, having been defeated at the general election, he found a seat in West Monmouthshire. He was appointed Solicitor-General and knighted in 1873; and, although he had not shown himself a very strenuous supporter of Mr Gladstone during that statesman's exclusion from power, he became Secretary of State for the Home Department on the return of the Liberals to office in 1880. His name was connected at that time with the passing of the Ground Game Act (1880), the Arms (Ireland) Act (1881), and the Explosives Act (1883). As Home Secretary at the time of the dynamite outrages he had to take up a firm attitude, and the Explosives Act was passed through all its stages in the shortest time on record. Moreover, as champion of law and order against the attacks of the Parnellites, his vigorous speeches brought him constantly into conflict with the Irish members. In 1884 he introduced an abortive Bill for unifying the municipal administration of London. He was indeed at that time recognized as one of the ablest and most effective leaders of the Liberal party; and when, after a brief interval in 1885, Mr Gladstone returned to office in 1886, he was made Chancellor of the Exchequer, an office which he again filled from 1892 to 1895. Between 1880 and 1892 Sir William Harcourt acted as Mr Gladstone's loyal and indefatigable lieutenant in political life. A first-rate party fighter, his services were of inestimable value; but in spite of his great success as a platform speaker, he did not impress the country as possessing much depth of conviction. It was he who coined the phrase about "stewing in Parnellite juice," and, when the split came in the Liberal party on the Irish question, even those who gave Mr Gladstone and Mr Morley the credit of being convinced Home Rulers could not be persuaded that Sir William had followed anything but the line of party expediency. In 1894 he introduced and carried a memorable Budget, which equalized the Death Duties on real and personal property. After Mr Gladstone's retirement in 1894 and Lord Rosebery's selection as Prime Minister Sir William became the leader of the Liberal party in the House of Commons, but it was never probable that he would work comfortably in the new conditions. His title to be regarded as Mr Gladstone's successor had been too lightly ignored, and from the first it was evident that Lord Rosebery's ideas of Liberalism and of the policy of the Liberal party were not those of Sir William Harcourt. Their differences were patched up from time to time, but the combination could not last. At the

general election of 1895 it was clear that there were divisions as to what issue the Liberals were fighting for, and the effect of Sir William Harcourt's Local Veto Bill on the election was seen not only in his defeat at Derby, which gave the signal for the Liberal rout, but in the set-back it gave to temperance legislation. Though returned for West Monmouthshire (1895, 1900), his speeches in debate only occasionally showed his characteristic spirit, and it was evident that for the hard work of Opposition he no longer had the same motive as of old. In 1898 the crisis arrived, and with Mr John Morley he definitely retired from the counsels of the party and resigned his leadership of the Opposition, alleging as his reason, in letters exchanged between Mr Morley and himself, the cross-currents of opinion among his old supporters and former colleagues. The split excited considerable comment, and resulted in much heart-burning and a more or less open division between the section of the Liberal party following Lord Rosebery and those who disliked that statesman's Imperialistic views. Though now a private member, Sir William Harcourt still continued to vindicate his opinions in his independent position, and his attacks on the Government were no longer restrained by even the semblance of deference to Liberal Imperialism. He actively intervened in 1899 and 1900, strongly condemning the Government's financial policy and their attitude towards the Transvaal; and throughout the Boer war he lost no opportunity of criticizing the South African developments in a pessimistic vein. One of the readiest parliamentary debaters, he savoured his speeches with humour of that broad and familiar order which appeals particularly to political audiences. In 1898–1900 he was conspicuous, both on the platform and in letters written to *The Times*, in demanding active measures against the Ritualistic party in the Church of England; but his attitude on that subject could not be dissociated from his political advocacy of Disestablishment. Sir William Harcourt married, first, in 1859, Thérèse, daughter of Mr T. H. Lister; and secondly, in 1876, Elizabeth, widow of Mr T. Ives and daughter of Mr J. L. Motley, the historian.

Harderwyk, a small town in the province of Gelderland, Netherlands, on the coast of the Zuider Zee, 28 miles north-east of and on the railway to Utrecht from Zwolle (Central Railway). It has a colonial recruiting office. As a seaport its trade is exclusively confined to the Zuider Zee. Population (1900), 7327.

Hardingstone, a parish in the Mid division of Northamptonshire, England, 2 miles south-south-east of Northampton. In it stands one of the original Eleanor Crosses, of which only three out of twelve remain, erected by King Edward I. to mark the resting-places of his queen's body on its way from Harby (Nottinghamshire) to burial at Westminster. Population about 3000.

Hardoi, a town and district of British India, in the Lucknow division of Oudh. The town is 63 miles north-east of Lucknow by rail. The population in 1881 was 10,026, in 1891 it was 11,152; the municipal income in 1897–98 was Rs.10,797; the registered death-rate in 1897 was 108 per 1000. The DISTRICT OF HARDOI has an area of 2324 square miles; the population in 1881 was 987,630, in 1891 it was 1,113,211, giving an average density of 479 persons per square mile. In 1901 the population was 1,093,201, showing a decrease of 2 per cent. The land revenue and rates were Rs.9,79,534, the incidence of assessment being a little over R.1 per acre; the cultivated area in 1896–97 was 905,405 acres, of which 209,042 were irrigated from tanks, wells, &c.; the number of police was 2273; the number of vernacular schools in 1896–97 was 92, with 4219 pupils; the registered death-rate in 1897 was 50·57 per 1000. There are three printing-presses, one of which issues a vernacular periodical. The district contains a larger urban population than any other in Oudh, the biggest town being Shahabad, with in 1891 a population of 20,153. It is traversed by the Oudh and Rohilkhand Railway from Lucknow to Shahjahanpur, with six stations; 62 miles in all.

Hardwar, a town of British India, in the Saharanpur district of the North-West Provinces, on the right bank of the Ganges, 17 miles north-east of Roorkee, with a railway station. The population of the municipal union in 1891 was 29,125; the municipal income in 1897–98 was Rs.39,246. It has an annual religious fair. The Ganges canal here takes off from the river. A branch railway to Dehra was opened in 1900.

Hardy, Thomas (1840–——), English novelist, was born in Dorsetshire, 2nd June 1840. His family was one of the branches of the Dorset Hardys, formerly of influence in and near the valley of the Frome, claiming descent from John Le Hardy of Jersey (son of Clement Le Hardy, lieutenant-governor of that island in 1488), who settled in the west of England. His maternal

THOMAS HARDY.
(*From a photograph by Elliott and Fry, London.*)

ancestors were the Swetman, Childs or Child, and kindred families, who before and after 1635 were small landed proprietors in Melbury Osmond, Dorset, and adjoining parishes. He was educated at local schools, 1848–54, and afterwards privately, and in 1856 was articled to Mr John Hicks, an ecclesiastical architect of Dorchester. In 1859 he began writing verse and essays, but in 1861 was compelled to apply himself more strictly to architecture, sketching and measuring many old Dorset churches with a view to their restoration. In 1862 he went to London (which he had first visited at the age of nine) and became assistant to the late Sir Arthur Blomfield, R.A. In 1863 he won the medal of the Royal Institute of British Architects for an essay on *Coloured Brick and Terra-cotta Architecture*, and in

the same year won the prize of the Architectural Association for design. In March 1865 his first short story was published in *Chambers's Journal*, and during the next two or three years he wrote a good deal of verse, being somewhat uncertain whether to take to architecture or to literature as a profession. In 1867 he left London for Weymouth, and during that and the following year wrote a "purpose" story, which in 1869 was accepted by Messrs Chapman and Hall. The manuscript had been read by Mr George Meredith, who asked the writer to call on him, and advised him not to print it, but to try another, with more plot. The manuscript was withdrawn and re-written, but never published. In 1870 Mr Hardy took Mr Meredith's advice too literally, and constructed a novel that was all plot, which was published in 1871 under the title *Desperate Remedies*. In 1872 appeared *Under the Greenwood Tree*, a "rural painting of the Dutch school," in which Mr Hardy had already "found himself," and which he has never surpassed in happy and delicate perfection of art. *A Pair of Blue Eyes*, in which tragedy and irony come into his work together, was published in 1873. In 1874 Mr Hardy married Emma Lavinia, daughter of the late T. Attersoll Gifford of Plymouth. His first popular success was made by *Far from the Madding Crowd* (1874), which, on its appearance anonymously in the *Cornhill Magazine*, was attributed by many to George Eliot. Then came *The Hand of Ethelberta* (1876), described, not inaptly, as "a comedy in chapters"; *The Return of the Native* (1878), the most sombre and, in some ways, the most powerful and characteristic of Mr Hardy's novels; *The Trumpet-Major* (1880); *A Laodicean* (1881); *Two on a Tower* (1882), a long excursion in constructive irony; *The Mayor of Casterbridge* (1886); *The Woodlanders* (1887); *Wessex Tales* (1888); *A Group of Noble Dames* (1891); *Tess of the D'Urbervilles* (1891), Mr Hardy's most famous novel; *Life's Little Ironies* (1894); *Jude the Obscure* (1895), his most thoughtful and least popular book; *The Well-Beloved*, a reprint, with some revision, of a story originally published in the *Illustrated London News* in 1892 (1897); *Wessex Poems*, written during the previous thirty years, with illustrations by the author (1898). In 1894 Mr Hardy was appointed a magistrate for Dorsetshire. In all his work Mr Hardy is concerned with one thing, seen under two aspects; not civilization, nor manners, but the principle of life itself, invisibly realized in humanity as sex, seen visibly in the world as what we call nature. He is a fatalist, perhaps rather a determinist, and he studies the workings of fate, or law (ruling through inexorable moods or humours), in the chief vivifying and disturbing influence in life, women. His view of women is more French than English; it is subtle, a little cruel, not as tolerant as it seems, thoroughly a man's point of view, and not, as with Mr Meredith, man's and woman's at once. He sees all that is irresponsible for good and evil in a woman's character, all that is untrustworthy in her brain and will, all that is alluring in her variability. He is her apologist, but always with a reserve of private judgment. No one has created more attractive women of a certain class, women whom a man would have been more likely to love or to regret loving. In his earlier books he is somewhat careful over the reputation of his heroines; gradually he allows them more liberty, with a franker treatment of instinct and its consequences. *Jude the Obscure* is perhaps the most unbiassed consideration in English fiction of the more complicated questions of sex. There is almost no passion in his work, neither the author nor his characters ever seeming able to pass beyond the state of curiosity, the most intellectually interesting of limitations, under the influence of any emotion. In his feeling for nature, curiosity sometimes seems to broaden into a more intimate communion. The heath, the village with its peasants, the change of every hour among the fields and on the roads of that English countryside which he has made his own—the Dorsetshire and Wiltshire "Wessex"—mean more to him, in a sense, than even the spectacle of man and woman in their blind, and painful, and absorbing struggle for existence. His knowledge of woman confirms him in a suspension of judgment; his knowledge of nature brings him nearer to the unchanging and consoling element in the world. All the entertainment which he gets out of life comes to him from his contemplation of the peasant, as himself a rooted part of the earth, translating the dumbness of the fields into humour. His peasants have been compared with Shakespeare's; he has the Shakespearean sense of their placid vegetation by the side of hurrying animal life, to which they act the part of chorus, with an unconscious wisdom in their close, narrow, and undistracted view of things.

Harfleur, a town in the arrondissement of Havre, department of Seine-Inférieure, France, 42 miles, in direct line, west by north of Rouen, on the railway from Paris to Havre. Principal industries are the founding of various metals, oil-refining, and the manufacture of soap. The port, which had been rendered almost inaccessible owing to the deposits of the Lézarde, has again become available since the opening, in 1887, of the Tancarville canal, connecting it with the Seine. The new port is half a mile from the old, and vessels drawing 18 feet can moor alongside its quays. Population (1901), 2686.

Harlingen, important trading town and seaport in the province of Friesland, Netherlands, 17 miles west of Leeuwarden by rail. Owing to the improvement of the port (Willemsport), and the railway and steamship connexion with Amsterdam, Bremen, and the southern provinces, trade with Great Britain (imports—coal, cotton, and jute for the manufacturing district of Twenthe; exports—cattle, butter, cheese, fish, potatoes, and wood) has much increased. Among the industries is the manufacture of margarine. A steam tramway has been opened to Sneek. Population (1900), 10,267.

Harmonic Functions. See SPHERICAL HARMONICS.

Harnack, Adolf (1851– ——), German theologian, was born on 7th May 1851 at Dorpat, in Russia, where his father held a professorship of pastoral theology. The son pursued his studies at this university and at Leipzig, where he took his degree; and immediately afterwards began lecturing as a *privat-docent*. These lectures, which dealt with such special subjects as gnosticism, the Apocalypse, &c., attracted considerable attention, and in 1876 he was appointed "extraordinary" professor. Three years later he was called to Giessen, where he became professor of Church history. There he collaborated with Von Gebhardt in *Texte und Untersuchungen zur Geschichte der altchristlichen Litteratur*, an irregular periodical, containing only essays in New Testament and patristic fields. In 1885 he published the first volume of his great work, the *History of Dogma*. In it Harnack traces the rise of dogma, by which he understands the authoritative doctrinal system of the 4th century and its development down to the Reformation. He considers that in its earliest origins Christian faith and the methods of Greek thought were so closely intermingled that much that is not essential to Christianity found its way into the resultant system. Therefore Protestants are not only free, but bound to

criticize it; indeed, for a Protestant Christian dogma cannot be said to exist. In 1886 Harnack was called to Marburg; and in 1889, in spite of violent opposition from the conservative section of the Church authorities, to Berlin. Here, somewhat against his will, he was drawn into a controversy on the Apostles' Creed, in which the party antagonisms within the Prussian Church had found expression. Harnack's view is that the creed contains both too much and too little to be a satisfactory test for candidates for ordination, and he would prefer a briefer symbol which could be rigorously exacted from all. At Berlin Harnack continued his literary labours. He undertook an edition of the Greek Fathers down to Eusebius, and a history of early Christian literature. He is one of the most prolific and most stimulating of modern Church historians, and has trained up in his "Seminar" a whole generation of teachers, who are carrying his ideas and methods throughout the whole of Germany and even beyond its borders. Harnack's own point of view is the historico-critical. His distinctive characteristics are: his claim for absolute freedom in the study of Church history and the New Testament; his distrust of speculative theology, whether orthodox or liberal; his interest in practical Christianity as a religious life and not a system of theology. His writings are remarkable for their clearness combined with picturesque grace of style.

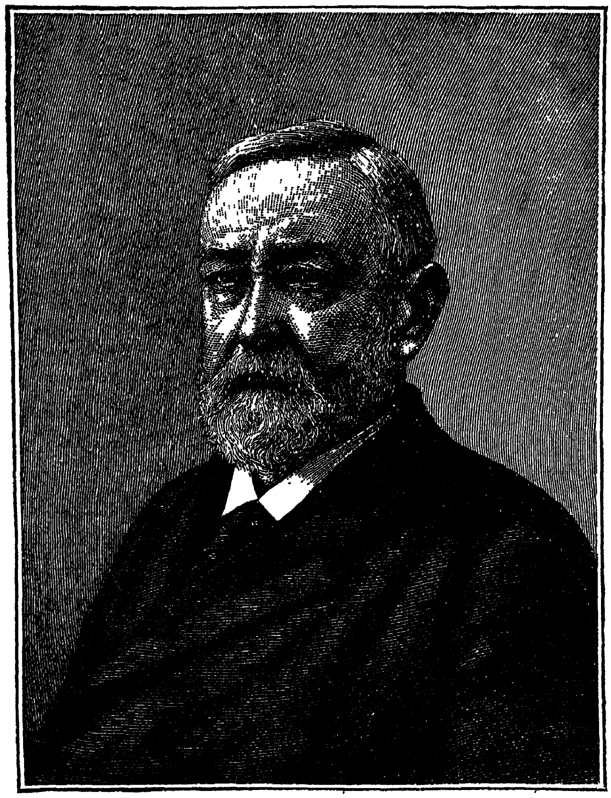
Haro, a town of Northern Spain, in the province of Logroño. It has increased in importance with the development of viticulture in its neighbourhood, and become the centre of a large export trade in wine. It has also manufactures of soap, liqueurs, brandy, preserves, candles, chalk, hats, and leather. Several casinos, a theatre, and various promenades have been constructed by the local authorities since 1880. Population (1897), 7976.

Harpenden, a village and urban district, Hertfordshire, England, in the Mid or St Albans division of the county, 5 miles south by east of Luton by rail, with stations on the Midland and Great Northern railways. In the Lawes Testimonial Laboratory there is a collection of over 50,000 bottles of samples of experimentally-grown produce, annual products, ashes, and soils. The late Sir John Bennet Lawes provided an endowment of £100,000 for the perpetuation of the agricultural experiments which he inaugurated here. The success of his association of chemistry with botany is shown by the fact that one field has grown wheat without intermission for 55 years without manure. Area of urban and rural districts combined, 5111 acres. Population (1891), 3603; (1901), 4725.

Harrisburg, capital of Dauphin county and of the state, Pennsylvania, U.S.A., in 40° 16′ N. and 76° 53′ W., on the east bank of the Susquehanna, at an altitude of 317 feet. Its site is level and the street plan regular. It derives an excellent water-supply from the river, and is well paved and sewered. It is on four railways—the Pennsylvania, the Northern Central, the Philadelphia and Reading, and the Cumberland Valley. The state capitol was destroyed by fire in 1897, and has since been rebuilt, greatly enlarged and improved. The manufacturing establishments in 1890 numbered 475, with $6,716,074 capital, and employed 6898 hands. Their products were valued at $10,538,444; of these nearly one-third in value were of iron and steel goods, the only prominent single item. The assessed valuation of real and personal property in 1890, on a basis of about two-thirds of the full value, was $26,631,875; the net debt was $1,183,234, and the rate of taxation was $17 per $1000. Population (1880), 30,762; (1890), 39,385; (1900), 50,167, of whom 2493 were foreign-born and 4107 were negroes. The death-rate in 1900 was 17·8.

Harrison, a town of Hudson county, New Jersey, U.S.A., on the Delaware, Lackawanna, and Western, the Erie and the Pennsylvania railways, at an altitude of 32 feet. Population (1880), 6898; (1890), 8338; (1900), 10,596, of whom 3633 were foreign-born.

Harrison, Benjamin (1833–1901), the twenty-third President of the United States, was born at North Bend, Ohio, 20th August 1833. His great-grandfather, Benjamin Harrison of Virginia, was a signatory of the Declaration of Independence. His grandfather, William Henry Harrison, who emigrated to Ohio, was in 1840 elected President of the United States. His father, John Scott Harrison, represented his district in the



Benjamin Harrison.

Congress of the United States. Benjamin's youth was passed upon the ancestral farm, and as opportunity afforded he attended the log school-house near his home. He was prepared for college by a private tutor at his father's house, and at the age of eighteen he graduated from Miami University, at that time the leading educational institution in the state of Ohio. From his youth he was diligent in his attention to his studies, and showed an avidity for the writings of Scott, Gibbon, and other classic English authors; and during his college life he showed a marked talent for extemporaneous speaking. He pursued the study of law, partly in the office of Bellamy Storer, a leading lawyer and judge of Cincinnati, and partly at his father's farm. At the age of twenty-one, having previously married, he went to Indianapolis. He had but one acquaintance in the place, the clerk of the Federal Court, who permitted him to occupy a desk in his office and place at the door his sign as a lawyer. Waiting for professional business, he was content to act as court crier for two dollars and a half a day; but he soon gave indications of his talent, and his studious

habits and attention to his cases rapidly brought him clients. Within a few years he took rank among the leading members of the profession at a bar which included some of the ablest lawyers of the country. His legal career was early interrupted by the Civil War. His whole heart was enlisted in the anti-slavery cause, and during the second year of the war he accepted a commission from the governor of the state as second lieutenant, and speedily raised a regiment. He was appointed its colonel, and as such continued in the Union army until near the close of the war, when he was breveted a brigadier-general for gallantry in the field. He participated with his regiment in various engagements during Buell's campaigns in Kentucky and Tennessee in 1862 and 1863; in Sherman's march on Atlanta in 1864; in the Nashville campaign; and was transferred early in 1865 to Sherman's army in its march through the Carolinas.

Allowing for this interval of military service, he applied himself exclusively for twenty-four years to his legal work, and became recognized as among the first lawyers of his state. The only office he held was that of reporter of the Supreme Court for two terms, which was strictly in the line of his profession. He was a devoted member of the Republican party, but not a politician in the strict sense. Once he became a candidate for Governor, in 1876, but his candidature was a forlorn hope, undertaken from a sense of duty, after the regular nominee had been forced to withdraw. He took a deep interest in the campaign which resulted in the election of Garfield as President, and was offered by him a place in his cabinet; but this he declined, having been elected a member of the United States Senate. He was chairman of the Committee on Territories, and took an active part in the admission of the new states of the north-west, especially of North and South Dakota. He served also on the Committee of Military and Indian Affairs, on Foreign Relations and others, was prominent in the discussion of matters brought before the Senate from these committees, advocated the restoration or enlargement of the navy, the reform of the civil service, and opposed the pension veto messages of President Cleveland. Mr Harrison was nominated by the Republican party for the Presidency in 1888, and successfully opposed Mr Cleveland, the candidate of the Democratic party. Among the measures and events distinguishing his term as President were the following:—The meeting of the Pan-American Congress at Washington; the passage of the McKinley Tariff Bill; the law suppressing the Louisiana lottery; the enlargement of the navy; further advance in civil service reform; the convocation by the United States of an international monetary conference; the establishment of commercial reciprocity with many countries of America and Europe; the peaceful settlement of the controversy with Chile; the Hawaiian annexation treaty; and the adjustment by arbitration with Great Britain of the Bering Sea fur-seal question. His administration was marked by a revival of American industries and a reduction of the public debt, and at its conclusion the country was left in an unexampled condition of prosperity and on friendly terms with foreign nations. He was nominated by his party in 1892 for re-election, but was defeated by Mr Cleveland, this result being due to the labour strikes which occurred during the Presidential campaign and arrayed the labour unions against the tariff party.

In 1898 Mr Harrison was retained by the government of Venezuela as its leading counsel in the arbitration of its boundary dispute with Great Britain. In charge of this duty he appeared before the international tribunal of arbitration at Paris in 1899, worthily maintaining the reputation of the American bar. He occupied a portion of his leisure after leaving public life in writing a book, entitled *This Country of Ours*, treating of the organization and administration of the government of the United States. He died at Indianapolis, Ind., on the 13th of March 1901. Mr Harrison's distinguishing trait of character, to which his success is to be most largely attributed, was his thoroughness. He was somewhat reserved in manner, and this led to the charge in political circles that he was cold and unsympathetic; but no one gathered around him more devoted and loyal friends, and his dignified bearing in and out of office commanded the hearty respect of his countrymen. (J. W. Fo.)

Harrison, Frederic (1831- ——), English jurist and author, was born in London, 18th October 1831. He was educated at King's College School and at Wadham College, Oxford, where, after taking a first-class in *Literæ Humaniores* in 1853, he became fellow and tutor. He was called to the bar in 1858, and, in addition to his practice in Equity cases, soon began to distinguish himself as an effective contributor to the higher-class reviews. Two articles in the *Westminster Review*, one on the Italian question, which procured him the special thanks of Cavour, the other on *Essays and Reviews*, which had the probably undesigned effect of stimulating the attack on the book, attracted especial notice. A few years later Mr Harrison worked at the codification of the law with Lord Westbury, of whom he contributed an interesting notice to Nash's biography of the chancellor. His special interest in legislation for the working classes led him to be placed upon the Trades Union Commission of 1867–69; he was secretary to the Commission for the Digest of the Law, 1869–70; and was from 1877 to 1889 professor of Jurisprudence and International Law under the Council of Legal Education. A follower of the Positive philosophy, he was one of the founders of Newton Hall in 1881; and he was editor and part author of the Positivist *New Calendar of Great Men* (1892). Of his separate publications, the most important are his lives of Cromwell (1888) and of William the Silent (1897), his *Historical Pieces* (1894), and *Meaning of History* (1862); his essays on *Early Victorian Literature* (1896), and *The Choice of Books* (1886) evince a rare faculty for generous admiration tempered by sound common-sense. An advanced Radical in politics and Progressive in municipal affairs, Mr Harrison in 1886 stood unsuccessfully for Parliament against Sir John Lubbock for London University. In 1889 he was elected an alderman of the London County Council, but resigned in 1893. In 1870 he married Ethel Berta, daughter of Mr William Harrison.

Harrogate, a municipal borough (incorporated 1884, extended 1900) and inland watering-place in the Ripon parliamentary division of Yorkshire, England, 16 miles north of Leeds by rail. Recent erections are Royal Baths, seven Established churches, Wesleyan and Baptist chapels; new buildings of the Harrogate Cottage Hospital, the Royal Bath Hospital, and the Rawson Convalescent Home; a Jubilee memorial statue of Queen Victoria (1887), Primitive Methodist chapel, Home for Incurables, Grand Opera House, and new Kursaal in course (1901) of erection. Public gardens were opened in 1888, and 36 acres of open ground, apart from the common (200 acres) are the property of the corporation, which also owns the Spa Concert Rooms and grounds, Harlow Moor, Crescent Gardens, Royal Bath Gardens, and other large open spaces, as well as Royal Baths, Victoria Baths, and Starbeck Baths. The mineral springs are vested in the corporation. Area (1891), 1287 acres; (1900, after extension), 3297 acres. Population (1881), 9482; (1891), 13,917; (1901), 28,414.

Harrow-on-the-Hill, a parish and town of England, 11 miles W.N.W. of St Paul's, London, in the Harrow parliamentary division of Middlesex, with stations on the London and North-Western and the Metropolitan Extension railways. Besides the church of St Mary's, which contains ancient brasses and other memorials, there are Roman Catholic (1894), Baptist, and Wesleyan places of worship. Harrow is celebrated for its School, founded in 1571 by John Lyon, and during the latter half of the 19th century frequently enlarged. Of recent additions the most important are the building which contains, besides schoolrooms, the Butler Museum (1886), the music school (1891), and a new drawing school (1897). The Harrow Technical School is under the control of the Middlesex County Council. The civil parish has an area of 10,027 acres, with a population of 13,000. The urban district population is (1901) 10,220.

Hart, Sir Robert, Bart. (1835- ——), Inspector-General of Chinese Customs, was born at Portadown, in Ulster, on 20th February 1835. He was educated at Taunton, Dublin, and Belfast, and graduated at Queen's College, Belfast, in 1853. In the following

Sir Robert Hart.
(From a photograph by the London Stereoscopic Company.)

year he received an appointment as student-interpreter in the China consular service, and after serving for a short time at the Ningpo vice-consulate, he was transferred to Canton, where after acting as secretary to the allied commissioners governing the city, he was appointed the local inspector of customs. There he first gained an insight into custom-house work. One effect of the Taiping rebellion was to close the native custom-house at Shanghai; and as the corrupt alternatives proposed by the Chinese were worse than useless, it was arranged by Sir Rutherford Alcock, the British consul, with his French and American colleagues, that they should undertake to collect the duties on goods owned by foreigners entering and leaving the port. Sir T. Wade was appointed to the post of collector in the first instance, and after a short tenure of office was succeeded by Mr H. N. Lay, who held the post until 1863, when he resigned owing to a disagreement with the Chinese Government in connexion with the Lay-Osborn fleet. During his tenancy of office the system adopted at Shanghai was applied to the other treaty ports, so that when on Mr Lay's resignation Mr Hart was appointed inspector-general of foreign customs, he found himself at the head of an organization which collected a revenue of upwards of eight million taels per annum at fourteen treaty ports. From the date when Mr Hart took up his duties at Peking, in 1863, he unceasingly devoted the whole of his energies to the work of the department, with the result that the revenue grew from upwards of eight million taels to nearly twenty-seven million, collected at the thirty-two treaty ports, and the customs staff, which in 1864 numbered 200, reached in 1901 a total of 5704. From the first Mr Hart gained the entire confidence of the members of the Chinese Government, who were wise enough to recognize his loyal and able assistance. Of all their numerous sources of revenue, the money furnished by Mr Hart was the only certain asset which could be offered as security for Chinese loans. For many years, moreover, it was customary for the British minister, as well as the ministers of other Powers, to consult him in every difficulty; and such complete confidence had Lord Granville in his ability and loyalty, that on the retirement of Sir T. Wade he appointed him minister plenipotentiary at Peking (1885). Sir Robert Hart, however—who was made a K.C.M.G. in 1882—recognized the anomalous position in which he would have been placed had he accepted the proposal, and declined the proffered honour. On all disputed points, whether commercial, religious, or political, his advice was invariably sought by the foreign ministers and the Chinese alike. Thrice only did he visit Europe between 1863 and 1902, the result of this long comparative isolation, and of his constant intercourse with the Peking officials, being that he learnt to look at events through Chinese spectacles; and his work, *These from the Land of Sinim*, shows how far this affected his outlook. The faith which he put in the Chinese made him turn a deaf ear to the warnings which he received of the threatening Boxer movement in 1900. To the last he believed that the attacking force would at least have spared his house, which contained official records of priceless value, but he was doomed to see his faith falsified. The building was burnt to the ground with all that it contained, including his private diary for forty years. When the stress came, and he retreated to the British Legation, he took an active part in the defence, and spared neither risk nor toil in his exertions. In addition to the administration of the foreign customs service, the establishment of a postal service in the provinces devolved upon him, and after the signing of the protocol of 1901 he was called upon to organize a native customs service at the treaty ports. Both the Chinese and the British Governments from time to time conferred honours upon him. By giving him a Red Button, or button of the highest rank, a Peacock's Feather, the Order of the Double Dragon, a patent of nobility to his ancestors for three generations, and the title of Junior Guardian of the Heir Apparent, the Chinese showed their appreciation of his manifold and great services; while under the seal of the British Government there were bestowed upon him the Orders of C.M.G. (1880), K.C.M.G. (1882), G.C.M.G. (1889), and a baronetcy (1893). He has also been the recipient of many foreign orders. Sir Robert Hart married in 1886 Hester, the daughter of Alexander Bredon, Esq., M.D., of Portadown, his family consisting of one son and two daughters.

Harte, Francis Bret (1839–1902), an American author, was born at Albany, New York, 25th August His father, a teacher in the Albany Female Academy, died during his boyhood. After a common-school education he went with his mother to California at the age of seventeen, afterwards working in that state as a teacher, miner, printer, express-messenger, secretary of the San Francisco mint, and editor. His first literary venture was a series of *Condensed Novels* (travesties of well-known works of fiction, somewhat in the style of Thackeray), published weekly in *The Californian*, of which he was editor, and reissued in book form in 1870. *The Overland Monthly*, the earliest considerable literary magazine on the Pacific coast, was established in 1868, with Harte as editor. His sketches and poems, which appeared in its pages during the next few years, attracted wide attention in the eastern states and in Europe. "The Luck of Roaring Camp" (1868), "The Outcasts of Poker Flat" (1869), the later sketch "How Santa Claus came to Simpson's Bar," and the verses entitled "Plain Language from Truthful James," combined humour, pathos, and power of character portrayal in a manner that indicated that the new land of mining-gulches, gamblers, unassimilated Asiatics, and picturesque and varied landscape had found its best delineator; so that Harte became, in his pioneer pictures, a sort of later Fenimore Cooper. Forty-four volumes were published by him between 1867 and 1898. After a year as professor in the University of California, Harte lived in New York, 1871–78; was United States consul at Crefeld, Germany, 1878–80; consul at Glasgow, 1880–85; and after 1885 resided in London, engaged in literary work. He died at Camberley, England, 5th May 1902.

Hartford, capital of Hartford county and of the state, Connecticut, U.S.A., on the western bank of the Connecticut river. It is well laid out, is divided into ten wards, has an excellent system of water-works, constructed by the city at a cost of $2,800,000, is well sewered, and is paved mainly with macadam. Its death-rate was 17·91 per 1000 in 1900. The New York, New Haven, and Hartford, and the Central of New England railways enter the city, and, with steamboats on the river, which is navigable to this point, give it a large commerce. In 1900 there were 888 manufacturing establishments, having a total capital of $30,500,047, and employing an average number of 13,363 wage-earners. The total products were valued at $31,145,715, among which the most important were bicycles and tricycles ($2,472,446) and foundry and machine shop products ($3,718,608). Hartford has also a large business in the printing and publishing of books. Among its newspapers should be mentioned the *Hartford Courant*, one of the oldest and best-known papers of New England. The chief business is in life and fire insurance. In 1890 the offices of six stock and five mutual-aid life insurance companies were situated here. The former had a capital exceeding $12,000,000 and assets exceeding $111,000,000. There were seven fire insurance companies, with a capital of over $10,000,000. Hartford is the seat of Trinity College, a Protestant Episcopal institution, founded in 1824, which in 1900 had 25 instructors and 128 students. The assessed valuation of real and personal property in 1900 was $69,760,630. The net debt was $3,641,971, and the rate of taxation was $17·50 per $1000. Population (1880), 42,015; (1890), 53,230; (1900), 79,850, of whom 23,758 were foreign-born and 1887 were negroes. The death-rate in 1890 was 24·4; in 1900 it was 19·4.

Hartford City, capital of Blackford county, Indiana, U.S.A., at the intersection of the Lake Erie and Western and the Pittsburg, Cincinnati, Chicago, and St Louis railways. Population (1890), 2287; (1900), 5912, of whom 572 were foreign-born.

Hartlepool (sometimes called EAST HARTLEPOOL) and **West Hartlepool,** twin seaports on the coast of Durham, England, the latter 12 miles, the former 15 miles, north-east from Stockton-on-Tees. The harbour, which embraces two tidal basins and six docks aggregating 83½ acres, in addition to timber docks of 57 acres, covers altogether 350 acres, and stretches between the two Hartlepools. The depth of water on the dock sills varies from 17½ feet at neap tides to 25 feet at spring tides. A breakwater three-quarters of a mile long protects the entrance to the harbour. Officially the two Hartlepools are considered as one port. They carry on an important trade in the export of coal, ships, machinery, iron and other metallic ores, woollens and cottons, and in the import of timber, sugar, iron and copper ores, and eggs. The exports increased from a total value of £624,531 in 1896 to £1,491,346 in 1900, and the imports from £1,630,486 to £2,004,481 in the same two years. Timber makes up 59 per cent. of the imports, and coal and ships each about 30 per cent. of the exports. The foreign trade employs about 800 vessels of 411,600 tons cleared annually, and the coasting trade some 1550 vessels of 530,700 tons. The port owns about 260 vessels of 380,000 tons, and a small fishing fleet. The principal industries are shipbuilding (iron), boiler and engineering works, iron and brass foundries, steam saw and planing mills, flour-mills, paper and paint factories, and soapworks. There are five graving docks, admitting vessels of 550 feet length and 10 to 21 feet draught. In 1889 a promenade, ¾ mile long, was made from the Heugh lighthouse to Throston. In East Hartlepool there are a new chapel of ease (St Andrew's) to the parish church, and a new United Presbyterian church; and in addition a Roman Catholic church and half-a-dozen Nonconformist chapels. The area of the municipal borough is 552 acres, and its population (1891) 21,288, and (1901) 22,737.

WEST HARTLEPOOL, which is of quite modern growth, but now the larger, was only incorporated in 1887. Its municipal area is 2454 acres, and its population (1891) 42,815, and (1901) 62,614. The municipal area embraces the three townships of Seaton Carew, Stranton, and Throston. There are several new churches, *e.g.*, St Aidan's and St Paul's, both in the Early English style, the Roman Catholic church (1893–94), the Swedish church, and the Presbyterian church; and conspicuous amongst the older sacred edifices are Christ Church, in the Gothic style, and St James's, Early Decorated. There are, further, several Nonconformist chapels. Stranton parish church dates from the middle of the 14th century, but was restored in 1889. The more important of the recent secular buildings are the municipal offices (1889), the free public library (1895), the technical institute and public hall (1896), and the market hall (rebuilt). The town possesses three clubs, three theatres, and the Ward-Jackson Memorial Park, opened in 1883.

Hartley, Sir Charles Augustus (1825–——), English engineer, was born in 1825 at Heworth, in Durham. Like most engineers of his generation he was engaged in railway work in the early part of his career, but subsequently he devoted himself to hydraulic engineering and the improvement of estuaries and harbours for the purposes of navigation. His services were employed in connexion with some of the largest and most important waterways of the world. After serving in the Crimea as a captain of engineers in the Anglo-Turkish

contingent, he was in 1856 appointed engineer-in-chief for the works carried out by the European Commission of the Danube for improving the navigation at the mouths of that river, and that position he retained till 1872, when he became consulting engineer to the Commission. In 1875 he was one of the committee appointed by the authority of the U.S.A. Congress to report on the works necessary to form and maintain a deep channel through the south pass of the Mississippi delta; and in 1884 the British Government nominated him a member of the International Technical Commission for widening the Suez Canal. In addition he was consulted by the British and other Governments in connexion with many other river and harbour works, including the improvement of the navigation of the Scheldt, Hugli, Don, and Dnieper, and of the ports of Odessa, Trieste, Kustendjie, Burgas, Varna, &c. He was knighted in 1862, and became K.C.M.G. in 1884.

Hartmann, Karl Robert Eduard von (1842-——), German philosopher, son of a general officer in the Prussian army, was born in Berlin on 23rd February 1842. He was educated for the army, and entered the artillery of the Guards as an officer in 1860, but a malady of the knee, which crippled him, forced him to quit the service in 1865. After some hesitation between music and philosophy he decided to make the latter the serious work of his life, and in 1867 the University of Rostock conferred on him the degree of doctor of philosophy without requiring residence. His reputation as a philosopher was established by his first book, *The Philosophy of the Unconscious*, which was published in 1869 and had by 1890 reached its tenth edition (in three volumes). This success, which was not rivalled by any of his subsequent writings, was largely due to the originality of its title, the diversity of its contents (von Hartmann professing to obtain his speculative results by the methods of inductive science, and making plentiful use of concrete illustrations), the fashionableness of its pessimism, the vigour and lucidity of its style; and these qualities will probably continue to give it the preponderance over its author's later and maturer works, in spite of all his protests. The conception of the Unconscious, by which von Hartmann describes his ultimate metaphysical principle, is not at bottom as paradoxical as it sounds: it is merely a new and mysterious designation for the Absolute of German metaphysicians, which lends itself to much manipulation by reason of its manifold ambiguities. This fact von Hartmann tardily recognized in an article in the *Archiv für systematische Philosophie* (August 1900), in which he distinguished nineteen different senses of the "unconscious," and confessed to great imperfections in his earlier treatment, but nevertheless maintained the validity of his metaphysical principle. Shorn in this way of the illusory empirical illustrations which rendered it interesting, the Unconscious appears as a combination of the metaphysic of Hegel with that of Schopenhauer. The Unconscious is both Will and Reason and the absolute all-embracing ground of all existence. Von Hartmann thus combines "pantheism" with "panlogism" in a manner adumbrated by Schelling in his "positive philosophy." Nevertheless Will and not Reason is the primary aspect of the Unconscious, whose melancholy career is determined by the primacy of the Will and the subservience of the Reason. Precosmically the Will is potential and the Reason latent, and the Will is void of reason when it passes from potentiality to actual willing. This latter is absolute misery, and to cure it the Unconscious evokes its Reason and with its aid creates the best of all possible worlds, which contains the promise of its redemption from actual existence by the emancipation of the Reason from its subjugation to the Will in the conscious reason of the enlightened pessimist. When the greater part of the Will in existence is so far enlightened by reason as to perceive the inevitable misery of existence, a collective effort to will non-existence will be made, and the world will relapse into nothingness, the Unconscious into quiescence. It is apparent from the above that although von Hartmann is a pessimist, and ably continues the tradition of Schopenhauer, his pessimism is by no means unmitigated. The individual's happiness is indeed unattainable either here and now or hereafter and in the future, but von Hartmann does not despair of ultimately releasing the Unconscious from its sufferings. He differs from Schopenhauer in making salvation by the "negation of the Will-to-live" depend on a collective social effort and not on individualistic asceticism. The conception of a redemption of the Unconscious also supplies the ultimate basis of von Hartmann's ethics. We must provisionally affirm life and devote ourselves to social evolution, instead of striving after a happiness which is impossible; in so doing we shall find that morality renders life less unhappy than it would otherwise be. Suicide, and all other forms of selfishness, are highly reprehensible. Epistemologically von Hartmann is a transcendental realist, who ably defends his views and acutely criticizes those of his opponents. His realism enables him to maintain the reality of Time, and so of the process of the world's redemption.

Von Hartmann is a very voluminous writer, his collected works extending to more than 12,000 pages. They may be classified into—A. Systematical, including * *Grundprobleme der Erkenntnisstheorie*; * *Kategorienlehre*; * *Das sittliche Bewusstsein*; * *Die Philosophie des Schönen*; * *Die Religion des Geistes*; * *Die Philosophie des Unbewussten* (3 vols., which now include his, originally anonymous, self-criticism, *Das Unbewusste vom Standpunkte der Physiologie und Descendenztheorie*, and its refutation). B. Historical and critical—* *Das religiöse Bewusstsein der Menschheit*; * *Geschichte der Metaphysik* (2 vols.); *Kant's Erkenntnisstheorie*; * *Kritische Grundlegung des transcendentalen Realismus*; *Über die dialektische Methode*; studies of *Schelling, Lotze, von Kirchmann*; *Zur Geschichte des Pessimismus*; *Neukantianismus, Schopenhauerismus, Hegelianismus*; * *Geschichte der deutschen Aesthetik seit Kant*; *Die Krisis des Christentums in der modernen Theologie*; *Philosophische Fragen der Gegenwart*; *Ethische Studien*; * *Moderne Psychologie*. C. Popular—*Soziale Kernfragen*; *Moderne Probleme*; *Tagesfragen*; *Zwei Jahrzehnte deutscher Politik*; *Das Judentum in Gegenwart und Zukunft*; † *Die Selbstzersetzung des Christentums*; *Gesammelte Studien*; *Der Spiritismus* and *Die Geisterhypothese des Spiritismus*. Of these, those marked * have been included among his selected works, while those marked † have been translated into English.

Harvard College, founded in 1636 at Cambridge, Massachusetts. It is the oldest and largest university in the United States. Since the election of Charles William Eliot as President in 1869 the standard both in the college and professional schools has been raised to the university level, and there have been founded the Graduate School, the Veterinary School, the Bussey Institution for Agriculture, and the School of Comparative Medicine. The Dental School (founded in 1867) has been organized on a sound basis, and the Lawrence Scientific School (founded in 1847) has been quickened into vigorous activity. In administration and in the life of its students Harvard has developed the characteristics of the older American colleges under the guiding principle of liberty: the free election of studies has been extended to the freshman class; compulsory attendance at religious exercises has been abolished (1885); the general government, and even the Divinity School, have been purged of sectarianism, and freedom is accorded to instructors. In scholarship, Germany has furnished the model. The range of studies has been widened to keep pace with the immense extension of

knowledge, and the scientific method, which exacts of the student a large share of observation and research, prevails in all departments. With Johns Hopkins University, Harvard led the movement that has transformed higher education in the United States. In the college proper the requirements for entrance and for graduation have been raised, although many candidates complete in three years the number of courses requisite for the degree. The professional schools have systematized and lengthened their work, most of which is prescribed. The Law School, where instruction by the "case" method was introduced by Professor C. C. Langdell, Dean from 1870 to 1895, and the Divinity School, already require of their matriculants the degree of A.B. or its equivalent; and the Medical School now does the same; the Dental School likewise looks forward to becoming a graduate school. At the Law School and Dental School the course is three years; at the Medical School, four years. Each school has a separate faculty for internal administration, but in 1890 the College, Graduate School, and Scientific School were placed under the general control of the Faculty of Arts and Sciences, and in 1899 the Faculty of Medicine was created for the Medical, Dental, and Veterinary Schools.

Connected with the university are the Botanic Garden (founded 1807) and Gray Herbarium (1864); the university museum of natural history (founded, 1859, by Louis Agassiz, and largely supported by his son, Alexander Agassiz); the Peabody Museum (founded, 1866, by George Peabody), devoted to American archæology; the Fogg Art Museum (erected 1895); the Semitic Museum; chemical, physical, and metallurgical laboratories; the astronomical observatory (founded in 1843), which has maintained since 1891 a station at Arequipa, Peru; the Arnold Arboretum, for the study of arboriculture, forestry, and dendrology. The college and departmental libraries contain 577,000 bound volumes and as many pamphlets. The college has twelve large dormitories, two dining halls, a theatre for public ceremonies, a chapel, Phillips Brooks House for religious societies, an infirmary, a gymnasium, and large playgrounds and boathouses. On 31st July 1900 the invested capital was $12,614,448; the lands and buildings were worth about $12,250,000 more; the receipts for the year were $2,071,306, and the payments $1,584,123; the gifts and bequests of the preceding twelve months amounted to $835,101. In 1901 there were 496 teachers and 4297 students, the latter being distributed as follows: College, 1992; Scientific School, 507; Graduate School, 341; Divinity School, 28; Law School, 647; Medical School, 605; Dental School, 126; Veterinary School, 18; Bussey Institution, 33. In addition, the Summer School of 1900 had 987 students; Radcliffe College for women had in 1901, 449. The alumni of the university number 27,477 (15,763 A.B.'s, 4085 M.D.'s, 3291 LL.B.'s). (See also UNIVERSITIES and EDUCATION.)

Harvesting Machines. See AGRICULTURAL MACHINERY.

Harvey, a city of Cook county, Illinois, U.S.A. It is a manufacturing town of growing importance, south of and close to Chicago. Population (1900), 5395, of whom 982 were foreign-born.

Harwich, a municipal borough and seaport in the Harwich parliamentary division (since 1885) of Essex, England, on the Stour, 7 miles north-east of London by rail. A quay was opened by the Great Eastern Railway Company at Parkeston, 1 mile up the river, in 1883. The port is also the headquarters of the Royal Harwich Yacht Club. The registered shipping in 1899 consisted of 121 vessels of 14,096 tons. In 1888, 3170 vessels of 686,775 tons entered and 2952 of 670,924 tons cleared; in 1899, 3860 vessels of 916,371 tons entered and 3639 of 893,281 tons cleared. Area, 1526 acres. Population (1881), 7842; (1901), 10,019.

Harz Mountains, one of the systems which border the great North German plain on the south, between the Saale and Leine. Owing to its position, as the first range of altitudes which the northerly winds strike after crossing the North German plain, the climate on the summit of the Harz is generally raw and damp, even, relatively speaking, in summer. In 1895 an observatory was opened on the top of the Brocken, and the results of the first five years (1896–1900) showed a July mean of 50° Fahr., a February mean of 24·7°, and a yearly mean of 36·6° (an admittedly imperfect series of older records between 1836 and 1867 gave a yearly mean of 34·5°). During the same five years the rainfall averaged 64½ inches annually. But whilst the summer is thus relatively ungenial on the top of the Harz, the usual summer heat of the lower-lying valleys is greatly tempered and cooled; so that, superadding this to the natural attractions of the scenery, the deep, dark forests, and the crowd of legendary and romantic associations which cling to every fantastic rock and ruined castle, the Harz is a favourite summer resort of the German people. Amongst the more popular places of resort are Harzburg, with the Canossa obelisk (50 feet high), dedicated to Bismarck and put up in 1877; Thale and the Bodethal, with the rock scenery of the Rosstrappe and the Hexentanzplatz; Blankenburg, with the Teufelsmauer and the Hermannshöhle; Wernigerode, Ilsenburg, Grund, Lauterberg, Hubertusbad, Alexisbad, and Suderode. Some of these, and other places not named, add to their natural attractions the advantage of mineral springs and baths, pine-needle baths, whey cures, &c. In spite of the mountainous nature of the region, the Harz is penetrated by some half-a-dozen railways, amongst them being a rack-railway up the Brocken, opened in 1898. The Harz is one of the richest mineral storehouses in Germany. Here silver and lead, to say nothing of other ores, have been mined for several hundred years, principally at Klausthal and St Andreasberg in the Upper Harz. Near the latter town is one of the deepest mining shafts in Europe, namely, the Samson, which goes down 2790 feet, or 720 feet below the level of the sea. For the purpose of getting rid of the water, and obviating the flooding of such deep workings, it has been found necessary to construct drainage works of some magnitude. As far back as 1777–99 the Georgsstollen was cut through the mountains from the east of Klausthal westwards to Grund, a distance of 4 miles or so; but this proving insufficient, another sewer, the Ernst-Auguststollen, no less than 14 miles in length, was made from the same neighbourhood to Gittelde, at the west side of the Harz in 1851–64.

See *Der Harz,* by various writers, edited by HANS HOFFMANN (Leipzig, 1899); VON GRODDECK, *Abriss der Geognosie des Harzes* (2nd edition, Klausthal, 1883); GÜNTHER, *Der Harz in Geschichts-Kultur- und Landschafts-bildern* (Hanover, 1885); PROHLE, *Harzsagen* (2nd edition, Leipzig, 1886); *Zeitschrift des Harzvereins* (annual since 1868, Wernigerode).

Haslemere, a town of England, in the south-west corner of Surrey, with a station 12 miles south-west from Guildford. It stands at an altitude of over 500 feet, between the bold hills (900 feet) of Hindhead and Blackdown. The invigorating air and fine scenery of the place, with its copses and abundance of heather and gorse, have made the district round Haslemere a favourite place of residence in recent years, particularly for literary and artistic society. Lord Tennyson spent most of his time at Aldworth, his property on Blackdown; Professor Tyndall

built a house on Hindhead, and thereby set an example which was followed by many others; George Eliot stayed for some time at Shottermill, 2 miles from Haslemere; and since about 1880 the number of new houses has gone on increasing, till the aspect of the neighbourhood has been completely changed. The town too has been modernized. The principal mansion in the district is Lythe Hill, built by the late Mr J. Stewart Hodgson. The population of Haslemere itself is 2613, and of Hindhead 666, but the number of people for whom Haslemere station is the railway centre is very much larger.

Haslingden, a municipal borough (1891) and market-town in the Rossendale and Heywood parliamentary divisions of Lancashire, England, 4 miles south-south-east of Accrington by rail. Two Established churches have been recently erected. The town, steadily increasing in importance, has cotton, woollen, and engineering works; quarrying and brickmaking are carried on in the neighbourhood. Area, 8196 acres. Population (1881), 16,298; (1901), 18,543. The borough, as incorporated, comprised several townships and parts of townships, but under the Local Government Act of 1894 these were united into one civil parish.

Haspe, a town of Prussia, province of Westphalia, 10 miles north-east of Barmen by rail. It has various iron-works, boiler-works, chemical factories, &c. Population (1885), 8903; (1900), 16,040.

Hasselt, a town of Belgium, capital of the province of Limburg, 47 miles east of Brussels, at an important junction of railway lines connecting it with towns in Holland and with the other principal places of Belgium. Its gin is reputed the finest distilled in the country. Its manufactures include oil, tobacco, and chemical and non-chemical manures. Population (communal, 1899), 15,002.

Hastings, one of the Cinque Ports, a municipal, county (1888), and parliamentary borough, and market-town of Sussex, England, 60 miles south-south-east of London by rail. The limits of the municipal and county borough were in 1897 extended, and now exceed those of the parliamentary borough. In 1885 the parliamentary representation was reduced to one member. Among the churches may be noted Christ Church (1875), costing over £23,000, and the church of St John the Evangelist (1881), All Souls' (1890), and a Catholic church (1882). Educational institutions include the grammar school (1883), school of science and art (1878), technical schools, and numerous board schools. The town hall, costing £20,000, dates from 1880. Other buildings are a theatre (1882), a music hall (1899), baths (1897), costing £60,000; convalescent home (1886), and hospital (1887). A second pier, that of St Leonards, 950 feet long, with a large pavilion, was opened in 1891. Alexandra Park, 75 acres, laid out at a cost of about £35,000, was opened in 1882. Population of municipal and county borough on unextended area (2194 acres) (1881), 42,258; (1891), 52,223. Extended area, 4769 acres; population (1891), 63,072; (1901), 65,528.

Hastings, capital of Adams county, Nebraska, U.S.A., at an altitude of 1933 feet. It has a regular plan, the water-supply and sewerage systems are excellent, and four railways enter it—the Burlington and Missouri River, the Fremont, Elkhorn, and Missouri Valley, the Missouri Pacific, and St Joseph and Grand Island. It is the seat of Hastings College, a Presbyterian institution, founded in 1882, which in 1899 had 10 instructors and 149 students, 68 of whom were women. Population (1880), 2817; (1890), 13,584; (1900), 7188, of whom 1253 were foreign-born.

Hatch, Edwin (1835–1889), English theologian, was born at Derby, 4th September 1835. He was educated at King Edward's School, Birmingham, under Dr James Prince Lee, afterwards Bishop of Manchester, the preceptor of Archbishop Benson and Bishops Lightfoot and Westcott. Hatch became scholar of Pembroke College, Oxford, took a second-class in Classics in 1857, and was Pusey and Ellerton Scholar in 1858. For some time he was professor of Classics in Trinity College, Toronto, but returned to Oxford in 1867, and was made Principal of St Mary's Hall, a post which he held until 1885. In 1883 he was presented to the living of Purleigh in Essex, and in 1884 was appointed University reader in ecclesiastical history. He had many struggles to pass through in early life, which tended to discipline his character and to form the habits of severe study and the mental independence of view for which he was afterwards distinguished. He was the first editor of the University official *Gazette*, and of the *Student's Handbook to the University*. He took a principal part in the preparation of a concordance to the Septuagint, published after his death. But he established his reputation chiefly by his treatises *On the Organization of the Early Christian Churches* (the Bampton Lectures for 1880), and on the *Influence of Greek Ideas and Usages on the Christian Church* (the Hibbert Lectures for 1888). These works attracted much attention, and provoked no little criticism on account of the challenge they appeared to throw down to the traditional views in vogue at the time of their appearance. But the research and fairness displayed were admitted on all hands. Hatch died, worn out with labour and greatly regretted, on 10th November 1889. He was a contributor of some important articles to the ninth edition of the *Encyclopædia Britannica*. (J. J. L*.)

Hatfield, or Bishop's Hatfield, a market-town and railway station in the St Albans parliamentary division of Hertfordshire, England, 7 miles W. by S. of Hertford. Hatfield forms part of a rural district. Partly in consequence of the increased importance of Hatfield House in recent years, as the residence of the Marquis of Salisbury, the station has become a more important one for purposes of the Great Northern system, and the town has spread out. Area of the parish, 12,884 acres. Population (1891), 4330; of the rural district (1891), 6963; (1901), 7551.

Hatherley, William Page Wood, Baron (1801–1881), Lord Chancellor of Great Britain, son of Sir Matthew Wood, a London alderman and lord mayor who became famous for befriending Queen Caroline and braving George IV., was born 29th November 1801. He was educated at Winchester, Geneva University, and Trinity College, Cambridge, where he became a fellow after being 24th wrangler in 1824. He entered Lincoln's Inn, and was called to the bar in 1824, studying conveyancing in Mr John Tyrrell's chambers. He soon obtained a good practice as an Equity draughtsman and before parliamentary committees, and in 1830 married Miss Charlotte Moor. In 1845 he became Q.C., and in 1847 was elected to Parliament for the city of Oxford as a Liberal. In 1849 he was appointed Vice-Chancellor of the County Palatine of Lancaster, and in 1851 was made Solicitor-General and knighted, vacating that position in 1852. When his party returned to power in 1853, he was raised to the bench as a Vice-Chancellor. In 1868 he was made a lord justice of appeal, but before the end of the year was selected by Mr Gladstone to be Lord Chancellor, and was raised to the peerage as Lord Hatherley of Down Hatherley. He retired in 1872 owing to failing eyesight, but sat occasionally as a law lord. His wife's death in

1878 was a great blow, from which he never recovered, and he died 10th July 1881. Dean Hook said that Lord Hatherley—who was a sound and benevolent supporter of the Church of England—was the best man he had ever known. He was a particularly clear-headed lawyer, conscientious and industrious, and his judgments—always delivered extempore—commanded the greatest confidence both with the public and the legal profession.

Hathras, a town of British India, in the Aligarh district of the North-West Provinces, 29 miles north of Agra. Population (1881), 25,656; (1901), 41,849. The municipal income in 1897–98 was Rs.32,670. It is an important centre of local trade in sugar and grain, and is connected by a light railway with Muttra, and by a branch (6 miles, opened in 1898) with Hathras junction, on the East Indian main line.

Hatton, John Liptrot (1809–1886), English musical composer, was born at Liverpool, 12th October 1809. He was virtually a self-taught musician, and besides holding several appointments as organist in Liverpool, appeared as an actor on the Liverpool stage, subsequently finding his way to London as a member of Macready's company at Drury Lane in 1832. Ten years after this he was appointed conductor at the same theatre for a series of English operas, and in 1843 his own first operetta, *Queen of the Thames*, was given with success. Staudigl, the eminent German bass, was a member of the company, and at his suggestion Hatton wrote a more ambitious work, *Pascal Bruno*, which, in a German translation, was presented at Vienna, with Staudigl in the principal part; the opera contained a song, "Revenge," which the basso made very popular in England, though the piece as a whole was not successful enough to be produced here. Hatton's excellent pianoforte playing attracted much attention in Vienna; he took the opportunity of studying counterpoint under Sechter, and wrote a number of songs, obviously modelled on the style of German classics. In 1846 he appeared at the Hereford Festival as a singer, and also played a pianoforte concerto of Mozart. He undertook concert tours about this time with Sivori, Vieuxtemps, and others. From 1848 to 1850 he was in America; on his return he became conductor of the Glee and Madrigal Union, and from about 1853 was engaged at the Princess's Theatre to provide and conduct the music for Charles Kean's Shakespearean revivals. He seems to have kept this appointment for about five years. In 1856 a cantata, *Robin Hood*, was given at the Bradford Festival, and a third opera, *Rose, or Love's Ransom*, at Covent Garden in 1864, without much success. In 1866 he went again to America, and from this year Hatton held the post of accompanist at the Ballad Concerts, St James's Hall, for nine seasons. In 1875 he went to Stuttgart, and wrote an oratorio, *Hezekiah*, given at the Crystal Palace in 1877; like all his larger works, it met with very moderate success. Hatton excelled in the lyrical forms of music, and, in spite of his distinct skill in the severer styles of the madrigal, &c., he won popularity by such songs as "To Anthea," "Good-Night, Beloved," and "Simon the Cellarer," the first of which may be called a classic in its own way. His glees and part-songs, such as "When Evening's Twilight," are still reckoned among the best of their class; and he might have gained a place of higher distinction among English composers had it not been for his irresistible animal spirits and a want of artistic reverence, which made it uncertain in his younger days whether, when he appeared at a concert, he would play a fugue of Bach or sing a comic song. He died at Margate, 20th September 1886. (J. A. F. M.)

Hatvan, a market-town of Hungary, in the county of Heves. Being situated at the junction of the railway lines leading from Budapest to the northern and north-eastern parts of the country, it carries on a very lively trade. Its industry is considerable, its sugar factory affording employment to about 500 workmen, and producing 60,000 metric centners of refined sugar a year. Population (1900), 9707.

Haubourdin, a town in the arrondissement of Lille, department of Nord, France, 4 miles south-west of Lille by rail, situated on the canalized Haute Deûle, and commanded by a fort and a battery. Public buildings of interest include the fine castle of Beaupré, built by the Spaniards in the 16th century; a hospital of the 15th century, and the chapel of the Crépins, built in 1347. The principal industries are starch and glucose, textile fabrics, oil and oil-cake, distilling, potash-refining, and dyeing. Port traffic (1900), 70,835 tons. Population (1876), 5115; (1901), 8485.

Haugesund, a seaport town of Norway, county of Stavanger, on the west coast, 34 miles north by west of Stavanger, an important fishing centre. Herrings are exported to the annual value of £100,000 to £200,000, also mackerel and lobsters. The total trade was valued at £460,250 in 1900. The Vigsnäs iron-mines were closed in 1896. The principal imports are coal and salt. There are factories for woollen goods and a margarine factory. Haugesund is the reputed death-place of Harold Haarfager, to whom an obelisk of red granite (45 feet high) was erected in 1872, 1¼ miles north of the town. Population (1875), 4102; (1900), 7935.

Hausa, sometimes incorrectly written Haussa, Houssa, or Haoussa, a numerous and important people inhabiting about half a million square miles in the western and central Sudan. Their country, roughly speaking, extends from 8° N. to 14° N., and from 4° E. to 11° E. By the terms of a proclamation dated 1st January 1901 a British protectorate was declared over the whole of this immense territory, including also the province of Bornu, which borders on Lake Chad. Since then British officers in charge of Hausa troops have had frequent fights with the slave-raiders of the interior. A considerable time must, however, elapse before slave-raiding can be extinguished and the protectorate be rendered effective. The Hausa people are believed to number altogether fifteen millions. They are quite distinct from all the tribes by whom they are surrounded, and in physical development far superior. Though their skin is as black as that of any African native, their lips are not so thick nor their hair so curly as those of the ordinary negro. They excel in physical strength. The average Hausa will carry on his head a load of ninety or a hundred pounds without showing the slightest signs of fatigue during a long day's march. When carrying their own goods it is by no means uncommon for them to take double this weight. Their general look of intelligence cannot but strike the traveller as he meets with them in their capacity of traders in all the surrounding districts. Their food consists chiefly of guinea corn (*sorghum vulgare*), which is ground up and eaten as a sort of porridge mixed with large quantities of red pepper. The Hausas attribute their superiority in strength to the fact that they live on guinea corn instead of yams and bananas, which form the staple food of the tribes on the river Niger. The Hausas carry on agriculture chiefly by slave labour; they are themselves born traders, and as such are to be met with in almost every part of Africa north of the equator. Small colonies of them are to be found in towns as far distant from one another as Lagos, Tunis, Tripoli, Alexandria, and Suakin.

The chief articles of trade are cloth, salt, kola nuts, ivory, leather, and spices. The centre of the cloth manufacture is the town of Kano, which has a population of at least 100,000, and the market-place of which has an average daily attendance of from 20,000 to 25,000. The cloth is made of cotton grown in the country, woven on small handlooms, and dyed either with indigo or with a scarlet dye obtained from the bark of a tree. If the Hausa history, which now exists in written form, be correct, the manufacture of this cloth has been carried on in Kano for 950 years. Kano and the district around it clothes half the population of the Sudan. The kola nut, which is chewed by almost every native of Hausaland, is brought from the country which lies at the back of the Gold Coast Colony. In taste it is almost as bitter as quinine. It takes the place of any other stimulant, and by keeping off the pangs of hunger enables the Hausas to work for a long time without food. The Hausas, though not a military race at all, nevertheless make exceedingly good soldiers when drilled and led by European officers. Their value was discovered in the first Ashanti war, and by the year 1902 there were over 5000 employed either as soldiers or police on the west coast or on the river Niger. They have been employed by the French as far away as in Madagascar.

Government.—Hausaland consists of a large number of nearly independent states owing a nominal allegiance to the sultan of Sokoto. The various kings are for the most part uncontrolled despots. The tribute which is paid by the smaller towns to the larger, and by the larger to Sokoto, consists almost entirely of slaves. In order to obtain the required number, which in the case of a large town comes to several thousands, the more powerful kings are constantly engaged in raiding the less powerful. In the Kano market there are usually not less than 500 slaves on sale. Most of the kings and of the ruling class are not Hausas, but belong to a tribe variously called Fulah, Fulani, Fulbe, or Fullatah. Whilst the Hausas are a quiet commercial people, the Fulahs are a race of soldiers and rulers. They have been the ruling class in Hausaland for about two centuries. They were in former time a race of herdsmen, and practically all the cattle in the country round belong to them. They are responsible for most of the slave raiding. At least a third of the inhabitants of the country are in a state of slavery.

The *language* is the lingua franca over practically all Africa north of the equator and west of the valley of the Nile. It is a rich sonorous language, with a vocabulary containing perhaps 10,000 words. About a third of the words which the language contains are connected with Arabic roots, nor are these words which the Hausas could well have borrowed in anything like recent times from the Arabs. Many words representing ideas or things with which the Hausas must have been familiar from the very earliest time are obviously connected with Arabic or Semitic roots. There is a certain amount of resemblance between the Hausa language and that spoken by the Berbers to the south of Tripoli and Tunis. This language, again, has several striking points of resemblance with Coptic. If, as seems likely, it should prove possible in the future to demonstrate the connexion between these three languages, such connexion would serve to corroborate the Hausa tradition that their ancestors came from the very far east away beyond Mecca. The Hausa language has been reduced to writing for at least a century, possibly for very much longer. It is the only language in tropical Africa which has been reduced to writing by the natives themselves, the character used being a modified form of Arabic. Some fragments of literature exist, consisting of political and religious poems, together with a limited amount of native history. A volume, consisting of history and poems reproduced in facsimile, with translations, has been published by the Cambridge University Press.

Religion.—About one-third of the people are professed Mahommedans, one-third are heathen, and the remainder have apparently no definite form of religion. Mahommedanism as a dominant power only dates from the beginning of the 19th century. In 1802 the Mahommedan Fulah sheik Othman proclaimed a sort of religious war, and after suffering many defeats, at length succeeded in establishing himself at Sokoto as ruler over the greater part of the Hausa states. Ever since then the ruler of Sokoto has been acknowledged as the religious head of the whole country, and tribute has been paid to him as such. The Hausas who profess Mahommedanism are extremely ignorant of their own faith, and what little religious fanaticism exists is chiefly confined to the Fulahs. Large numbers of the Hausas start every year on the pilgrimage to Mecca, travelling sometimes across the Sahara desert and by way of Tripoli and Alexandria, sometimes by way of Wadai, Darfur, Khartum, and Suakin. The journey often occupies five or six years, and is undertaken quite as much from trading as from religious motives. Mahommedanism is making very slow, if any, progress amongst the Hausa people. The greatest obstacle to its general acceptance is the institution of the Ramadan fast. In a climate so hot as that of Hausaland, the obligation to abstain from food and drink from sunrise to sunset during one month in the year is a serious difficulty. No important attempt had, up to 1902, been made to introduce Christianity, but the fact that the Hausas are fond of reading, and that native schools exist in all parts of the country, should greatly facilitate the work of Christian missionaries.

The greater part of Hausaland consists of thinly wooded country, with towns and villages scattered at frequent intervals. Every village is fortified in order to resist sudden attack from slave raiders. The largest towns are Kano, Yakoba (often called Garim Bauchi), Zaria, Katsena, Zinder, Gando, and Sokoto. The last two are of no great size, but are regarded as the centres of the whole country from a religious and political point of view. The country rises very slowly from the coast. Three hundred miles inland, at Lokoja, it is about 280 feet above the sea. The level of Kano, which is about 750 miles inland, is 1425 feet. One of the highest towns is Kachia, which is 2440 feet above the sea. It lies on a range of hills which attain an altitude of about 3800 feet, running from east to west at about 10° N. The rivers are small, and many of them cease running during the dry season, which lasts from December to June or July. During the wet season the grass, except in the densest parts of the forest land, grows to a height of about ten feet, but dies down entirely when the dry season begins. In the southern part of the country baggage animals are not available, except to a limited extent during the dry season. In the northern part horses, donkeys, and mules are used, and in the extreme north camels. There are no roads other than narrow paths about a foot wide. Hills similar in shape to the Table Mountain at Cape Town are a feature of the country. On the hilly country round Kachia are found several pagan tribes who wear no clothes and whose bodies are covered with hair. These were probably the original inhabitants of the Hausa country, and were driven by the Hausa people into the hills on their advance from the north, which, according to their tradition, occurred 950 years ago. The climate is very trying to the European, though it is perhaps slightly better than that of the river Niger and the West Coast. The natives do not suffer to any extent from fever unless they move from one part of the country to another at some distance from their own home. Leprosy is very common, especially in the inland towns. The chief currency of the country, except when slaves are used, consists of cowry shells, the average value of which is about the two-hundredth part of a penny.

Haussmann, Georges Eugène, Baron (1809–1891), the famous aedile of modern Paris, was the son of Nicolas Valentin Haussmann, a publicist and statistician, who rose in the public service under Louis Philippe. This Nicolas Valentin was the son of Nicolas Haussmann (1761–1846), an Alsatian who established himself at Versailles as a linen-draper and became one of the commissaries of the Convention in 1793, and the nephew of Jean Michel Haussmann (1749–1824), a distinguished chemist of Colmar who inaugurated an important chintz manufactory at Rouen and did much to advance the colour printing of textiles in Normandy. Born in Paris 27th March 1809, Georges Eugène first studied for the profession of a vocalist at the Conservatoire, but then entered a notary's office and qualified for the bar with a view to some administrative office. His advancement was accelerated by that of Louis Napoleon, and by 1851 he had risen to be Prefect of the Gironde. In 1852 Louis Napoleon visited Bordeaux, and was greatly struck by the adroitness with which the prefect had organized the demonstrations in his honour. In intercourse with Haussmann he was still further impressed by his grandiose

schemes for municipal improvements. In the following year he sent for him to Paris and made him Prefect of the Seine. With the aid of a very able engineer named Alphand, Haussmann in the course of the next twelve years completely transformed the ground plan of intramural Paris. It is not possible to do more than barely indicate a few of his most daring conceptions. In the forefront of these stand the design of the Place du Carrousel, the junction of the Louvre and the Tuileries by means of two monumental galleries, the building of the Halles Centrales, of a number of pretentious churches, and of a group of theatres, including the Nouvel Opéra. Passing by the external boulevards, which were almost entirely of his planning, he designed the Boulevards Strasbourg, Sébastopol, Malesherbes, and St Michel, besides improving and greatly enlarging the Boulevard St Germain. Even more striking still, perhaps, is the series of arterial streets which he cut through the tortuous thoroughfares of central Paris. Such were the Rue de Rivoli, the Rue La Fayette, the Rue de Rennes, the Rue Bonaparte, and the Rue des Écoles, in the construction of which the Donjon de St Jean de Latran was destroyed. The present Hôtel Dieu is merely one of the structures which he entirely rebuilt. His reforming zeal was directed with equal energy to the drainage, the water supply, the cemeteries, and the plantations of Paris. Among the metropolitan parks, for the present arrangement and dimensions of which he was mainly responsible, are the Bois de Vincennes, the Parc Monceau, the Parc Montsouris, the Buttes Chaumont, and the Bois de Boulogne, which he extended to the Seine in 1854. The Champs Élysées in its present form, and the avenues which radiate from the Arc de Triomphe, owe much to the hand of the same master designer; and the present Hôtel Carnavalet with its collections is due primarily to his initiative. To finance these stupendous schemes the municipality of Paris effected loans of between one and two million francs annually. Haussmann carried matters with a high hand, and assured the Parisians that the investment was a profitable one—nor has his prediction been altogether falsified. On the other hand, speculation in land was stimulated to an unwholesome degree, rents were enormously inflated, and malpractices of various kinds are said to have been prevalent. Great bitterness was caused by the transplantation of poor families and by encroachments upon certain outlying portions of the Luxembourg gardens, while no little political capital was made out of the multiplication of wide avenues, unsuitable for the erection of barricades, but admirably fitted for the operations of artillery.

Under the effective burlesque title of *Contes Fantastiques de Haussmann* a scathing attack was made upon Haussmann's methods in 1868 in a mordant pamphlet by Jules Ferry. Similar attacks were made in other quarters, and received semi-official sanction from the Cour des Comptes (Board of Audit), which in a special report described some of Haussmann's expedients as ingenious rather than strictly legal. He retained the confidence of the Emperor, but this availed less in 1869 than in 1853. He had to bend to the storm by submitting the Paris budget to the Chamber. Ollivier's attempt to liberalize the Government involved his fall on 2nd January 1870. He had been made a Senator (1857), Grand Cross of the Legion of Honour (1862), and Member of the Academy of Fine Arts (1867). Napoleon wished to retain his services, and offered him, it was rumoured, the title of Duc de Paris. He preferred a complete retirement at Nice on a small annual pension of 6000 francs. Subsequently he made several attempts to re-enter politics, and managed to secure a seat in the Chamber as Bonapartist deputy for Ajaccio from 1877 to 1881. He died at Paris on 11th January 1891, surviving by only a few weeks his wife, and leaving issue one daughter, wife of M. Camille Dollfus. He is commemorated in Paris street terminology by the Boulevard Haussmann, a name which the Municipal Council very nearly succeeded in altering in 1879; but Haussmann's real monument is modern Paris, of which he inaugurated, as was said, a new Stone Age. Old landmarks disappeared as if by magic under the stroke of his crayon, and new structures sprang up like the palaces of an Arabian tale. As Louis XIV. set the fashion to palace-builders with Versailles, so Haussmann, by the creation of a new Paris, excited to emulation the shapers of cities, and "to Haussmannize" has come to mean the substitution of monotonous avenues and rectilinear spaces for the crooked ways and irregular boundaries dear to the archæologist and the historian. To form any adequate conception of the extent of Haussmann's activities in these directions it is necessary to go through his somewhat dull *Mémoires* (1893), the third (and posthumous) volume of which bears the well-deserved sub-title, *Grands Travaux de Paris*. (T. SE)

Hautmont, a town in the arrondissement of Avesnes, department of Nord, France, 44 miles in direct line south-east of Lille; a junction on the railway from Paris to Brussels, and on the Sambre. There are very important forges, foundries, and iron-rolling mills, and various kinds of iron goods are extensively produced. Population, 10,000.

Havana, the capital of Cuba, the largest city of the West Indies, situated on the north coast of the island. The bay is capacious and land-locked, and on the town side is sea-walled and lined by handsome parks. At the southern end of the bay, at the old fort of Atares, the American Crittenden and others of the insurrectionary expedition of 1851 were shot. Regla, on the east side of the bay, contains the sugar-shipping wharves and the terminus of the railways leading to the eastern end of the island; it is connected with Havana by large ferry-boats. The older main portion of the city is on a low plain, once enclosed by a mediæval wall. It occupies a septagonal peninsula lying between the river Almendaris on the west, the sea on the north, and Havana harbour on the east. On the south and west it is backed by an amphitheatre of hills, 150 feet high, crowned by the conspicuous fortifications of Castillo de Principe. The principal business streets, Calle Obispo and Calle O'Reilly, are narrow and closely built. Elsewhere wider avenues are found. There are many beautiful parks and drives, including the fine avenue known as the Prado. There are also many suburban pleasure resorts, and pretty villages such as Guines, Guanabacoa, Marianao, and Puentes Grandes. Throughout the city, and especially the more modern portion, there are many elaborate structures. The Havanese boast that the Teatro Taçon is the largest theatre in the world. Other notable buildings are the markets, the opera-house, the captain-general's palace, the hospitals, the university, the city prison, several churches (including the cathedral), and many club-houses. The many immense cigar factories are by no means unattractive features. Some of the houses of the wealthy, scattered throughout the city, are very handsome. They have always an inner courtyard, or *patio*, surrounded by tall stuccoed columns and ornamented with plants around a central fountain. The large industrial population lives mostly in densely crowded houses. The principal institutions of learning are the University of Havana and the large Jesuit College de Belen for boys. The latter has a museum and an observatory, where most

of the important astronomical and climatological data concerning Cuba have been collected; its library is especially rich in old volumes pertaining to Cuban life from the 16th century to the present. Among the numerous benevolent institutions are the Casa de Beneficencia, founded by Las Casas as an asylum for infants and the aged; hospitals for the sick of all classes, and an immense lazaretto for lepers in the western part of the city. A hospital for the insane is maintained a few miles south of Havana. Until recently the city was badly supplied with water, and its sewerage is still abominable. In 1895 a modern system of waterworks was installed by New York engineers, who also prepared plans for the solution of the sewerage problem. The city is well policed. Street railways radiate in several directions from the Paseo. The tramcars are worked by electricity. An extensive system of railways radiates from Havana, extending east to Santa Clara, west to Pinar del Rio, and south to Batabano and Cienfuegos. Coasting vessels from Havana ply round the island, and lines of steamers afford close connexion with the United States. Many European lines also sail to the city. The chief industry is the manufacture of tobacco. There are also manufactories of sweetmeats, candles, carriages, soap, perfumery, and glycerine, and breweries, rum distilleries, tanneries, and gas works. Havana commands the wholesale trade of all the western half of Cuba, including the provinces of Matanzas, Havana, and Pinar del Rio, and is the headquarters of all the commercial and banking interests of the island. The foreign and coastal shipping trade is extensive, the American tonnage alone amounting to 1,000,000 per annum. About 1200 ocean vessels, steam and sail, annually clear from Havana, while the sugar crop finds an outlet at all the principal ports. Population (1899), 235,981. (See CUBA.)

(R. T. H.)

Havel, a river of Prussia, having its origin in Lake Dambeck (223 feet) on the Mecklenburg high grounds, a few miles north-west of Neu-Strelitz, and after threading several lakes flowing south as far as Spandau. Thence it curves south-west, west, and north-west past Potsdam and Brandenburg, traversing another chain of lakes, and finally continues north-west until it joins the Elbe from the right some miles above Wittenberge after a total course of 221 miles and a total fall of only 158 feet. Its banks are mostly marshy or sandy, and the stream is navigable from the Mecklenburg lakes downwards. Several canals connect it with these lakes, as well as with other rivers—*e.g.*, the Finow canal with the Oder, the Ruppin canal with the Rhin, the Berlin–Spandau navigable canal (5½ miles) with the Spree, and the Plaue–Ihle canal with the Elbe. The Sakrow–Paretz canal, 11 miles long, cuts off the deep bend at Potsdam. The most notable of the tributaries is the Spree (227 miles long), which bisects Berlin and joins the Havel at Spandau. Area of river basin, 10,159 square miles.

Haverfordwest, a municipal and county borough (with its own lord-lieutenant), market-town, and railway station, Pembrokeshire, Wales, 63 miles west by north of Swansea. Since 1885 it has united with Pembroke, Fishguard, Milford, Narberth, Tenby, and Wiston to return one member to Parliament. The old grammar-school has been provided with new buildings, a temperance hall erected, and a high-class school for girls established. There are a shire hall, Masonic hall, two market buildings, a reading-room, and an infirmary. The charities belonging to the borough are considerable. Area, 1382 acres. Population (1881), 6398; (1901), 6007.

Haverhill, a city of Essex county, Massachusetts, U.S.A., in 42° 47′ N., 71° 40′ W., on the Merrimack at the head of tide, and on the Boston and Maine Railway. Its area of 28 square miles is divided into seven wards; its plan is irregular; it has a good water-supply, pumped from neighbouring lakes; it is sewered, and the streets are paved, mainly with macadam. It is essentially a manufacturing city. In 1890 its manufacturing establishments numbered 734, with an invested capital of $8,084,272; 15,200 hands were employed, and the product was valued at $25,394,535. Of this not less than four-fifths consisted of boots and shoes. The assessed valuation of real and personal property in 1900 was $26,443,933, the net debt was $1,486,522, and the rate of taxation was $17·40 per $1000. Population (1880), 18,472; (1890), 27,412; (1900), 37,175, of whom 8530 were foreign-born, and 373 were negroes. The death-rate in 1900 was 15·1.

Haverstraw, a village of Rockland county, New York, U.S.A., in 41° 03′ N. and 73° 58′ W., on the west shore of Haverstraw Bay, an enlargement of the Hudson. It is on three railways—the New York, Ontario, and Western, the New Jersey and New York, and the West Shore. Its chief industry is brickmaking. Population (1880), 3506; (1890), 5070; (1900), 5935.

Havre, Le, a town and seaport of France, on the English Channel at the mouth of the Seine, department of Seine-Inférieure, 142 miles from Paris by rail, with a population in 1886 of 109,199, in 1896 of 117,009, and in 1901 of 129,044. Its trade has been estimated at one-fifth or one-sixth of that of all France. The annual movement of the port amounts to nearly 13,000 ships, approaching 6,000,000 tons, and producing more than £3,200,000 duty at the custom-house. In 1899, 6348 vessels entered the port and 6414 cleared, with a total of 5,837,997 tons; the value of exports reached £37,024,000, that of imports, £39,208,000. Fifty-one yachts, eleven of over 100 tons, belong to the port.

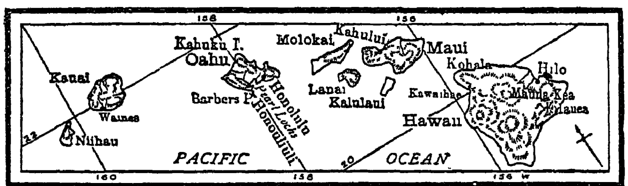
Le Havre owes its prosperity mainly to its advantageous situation. At each tide the water level does not vary more than 1 foot for three hours, thus permitting vessels to enter and clear freely during that interval. The appliances and resources of the port are constantly being improved. It now includes 9 wet docks, with an area of nearly 200 acres, and more than 8 miles of quays. The great transatlantic packet-boats berth in the Eure basin, into which the Tancarville canal (15½ miles long) enters, permitting river boats which could not attempt the estuary of the Seine to make the port direct. It is also between the same basin and the canal that the three dry docks (460, 500, and 600 feet long respectively, and from 65 to 130 feet wide) for the accommodation of large vessels are situated. There is a petroleum dock for the sole use of vessels carrying this dangerous commodity. The fortifications on the southern sea-front will be done away with, and on the west of the present jetties an area of about 120 acres will be surrounded by new piers and added to the present outer port. The channel directed towards the west will be equally accessible from the south-west and west-north-west. It will be excavated 15 feet below the zero level of the charts. The direction adopted will, as far as possible, remove the entrance to the port from the sand deposits in the bay of the Seine. The lock leading from the outer port into the Eure basin will have its flood-gate 13 feet below the zero level of the charts, and will allow large vessels to pass for six hours every tide. In the outer port itself the depth alongside the quay accessible to railway trains is to be deepened for a length of 1300 feet, so that the great transatlantic liners can regularly lie under conditions which will permit of their leaving at fixed hours.

The embellishment of the town corresponds with these improvements to the port. The boulevards which have replaced the ancient ramparts are lined with fine buildings. To the Hôtel de Ville and Palais de Justice, of comparatively recent date, is now added the Bourse. Among the large manufactories those producing war material have increased greatly in importance—founding cannon, and building gun-carriages and warships as well as merchant vessels. To these may be added a refinery

of argentiferous lead, a sugar refinery, petroleum, oil, soap, rice, and nickel works, a copper wire-drawing mill, and a manufactory of dye-stuffs. Important electrical works furnish the town with light and its trams with motive power. Le Havre also builds electric motors. Its *entrepôt* for tobacco leaf is the most important in France. England, Germany, and the United States of America are the countries with which the city holds most intercourse. There is weekly communication between Le Havre and New York by the magnificent steamships of the Compagnie Transatlantique Française.

Hawaiian or Sandwich Islands.—The treaty of commercial reciprocity with the United States, which took effect in 1876, has been justly called the most important event in Hawaiian history since 1843. It ushered in an era of unexampled prosperity, and set in motion a series of momentous changes. In the early part of Kalakaua's reign (1874–91) a political struggle began which culminated in the overthrow of the monarchy. It had been the aim of Kamehameha III. and his advisers to combine the native and the foreign elements under one government; to make the king the sovereign not of one race or class, but of all; and to extend equal and impartial laws over all inhabitants of the country. Kalakaua, however, seemed to regard himself as merely sovereign of the aboriginal Hawaiians, and residents of European or American descent as alien invaders. It appeared to be his chief aim to restore, to a great extent, the ancient system of personal government, under which he should have control of the public treasury. Thus he took it upon himself, on the 2nd of July

History.



G. V Darbishire & O J R Howarth *Engl Miles* 0 50 100 *Oxford, 1901.*

SKETCH MAP OF THE HAWAIIAN ISLANDS.

1878, and again on the 14th of August 1880, to dismiss a ministry without assigning any reason, after it had been triumphantly sustained by a test vote of the legislature. On the latter occasion he appointed Mr C. C. Moreno, who had come to Honolulu in the interest of a Chinese steamship company, as Premier and Minister of Foreign Affairs. This called forth the protest of the representatives of Great Britain, France, and the United States, and aroused such opposition on the part of both the foreigners and the better class of natives, that the king was obliged, after four days of popular excitement, to remove the obnoxious minister. On the 20th of January 1881 the king set out upon a tour around the world. He was received with royal honours in Japan, Siam, and Johore, and he then crossed British India by rail and visited the Khedive of Egypt. The royal party visited nearly all the capitals of Europe, and returned by way of Washington, arriving in Honolulu on the 29th of October 1881. During his absence his sister, Mrs Lydia Dominis, also styled Liliuokalani, acted as regent.

After the king's return the contest was renewed between the so-called National party, which favoured absolutism, and the Reform party, which sought to establish parliamentary government. The king took an active part in the elections, and also used his patronage to the utmost to influence legislation. For three successive sessions a majority of the legislature was composed of office-holders, dependent on the favour of the executive. Among the measures urged by the king and opposed by the Reform party were the project of a ten million dollar loan, chiefly for military purposes; the removal of the prohibition of the sale of alcoholic liquor to Hawaiians, which was carried in 1882; the licensing of the sale of opium; the chartering of a lottery company; the licensing of *kahunas*, or medicine men, &c. Systematic efforts were made to turn the constitutional question into a race issue, and the party cry was raised of "Hawaii for Hawaiians." Adroit politicians were not wanting to flatter the king's vanity, defend his follies, and teach him how to violate the spirit of the constitution while keeping the letter of the law. From 1882 till 1887 his prime minister was Walter Murray Gibson, a singular and romantic genius, at once a visionary adventurer and a shrewd politician, who had been imprisoned by the Dutch Government in Batavia in 1852 on a charge of inciting insurrection in Sumatra, and who had arrived at Honolulu in 1861 with the intention of leading a Mormon colony to the East Indies. To exalt his royal dignity, which was lowered by the fact that he was only an elected king, Kalakaua caused himself to be crowned with imposing ceremonies on the ninth anniversary of his election (12th February 1883). He was now no longer satisfied with being merely king of Hawaii, but aspired to what was termed the "Primacy of the Pacific." Accordingly Mr Gibson addressed a protest to the Great Powers, deprecating any further annexation of the islands of the Pacific Ocean, and claiming for Hawaii the exclusive right "to assist them in improving their political and social condition." In pursuance of this policy, two commissioners were sent to the Gilbert Islands in 1883 to prepare the way for a Hawaiian protectorate. On the 23rd of December 1886 Mr J. E. Bush was commissioned as minister plenipotentiary to the king of Samoa, the king of Tonga, and the other independent chiefs of Polynesia. He arrived in Samoa on 3rd January 1887, and remained there six months, during which time he concluded a treaty of alliance with Malietoa, which was ratified by his Government. The *Explorer*, a steamer of 170 tons, which had been employed in the copra trade, was purchased for \$20,000, and refitted as a man-of-war, to form the "nest-egg" of the future Hawaiian navy. She was re-named the *Kaimiloa*, and despatched to Samoa on 17th May 1887 to strengthen the hands of the embassy. As R. L. Stevenson wrote, "The history of the *Kaimiloa* is a story of debauchery, mutiny, and waste of Government property." At length the intrigues of the Hawaiian embassy gave umbrage to the German Government, and it was deemed prudent to recall it to Honolulu in July 1887. Meanwhile a reform league had been formed for the purpose of putting an end to the prevailing misrule and extravagance, and had the support of the volunteer military force known as the "Honolulu Rifles." The king had succeeded in carrying through the legislature of 1886 a Bill providing for an opium licence, as well as a Loan Act, under which a million dollars was borrowed in London. After this he went from one folly to another until his acceptance of two bribes—one of \$75,000 and another of \$80,000 for the assignment of an opium licence—precipitated the revolution of 1887. An immense mass meeting was held on 30th June, from which a committee was sent to the king with specific demands for radical reforms in the methods of administering the government. Overawed by the unanimity of the movement, and finding himself without support, he yielded without a struggle, dismissed his ministry, and signed a new constitution on the 7th of July 1887, revising that of 1864, which was intended to put an end to personal government and to make the cabinet responsible only to the legislature. By its terms office-holders were made ineligible for seats in the

legislature, and no member of the legislature could be appointed to any civil office under the Government during the term for which he had been elected. The members of the Upper House, instead of being appointed by the king for life, were henceforth to be elected for terms of six years by electors possessing a moderate property qualification. The remainder of Kalakaua's reign teemed with intrigues and conspiracies to restore autocratic rule. One of these came to a head on the 30th of July 1889, but the insurrection was promptly suppressed. Seven of the insurgents were killed and a larger number wounded. There can be little doubt that the late king and his sister, who succeeded him, were accessory to this ill-advised outbreak. In order to recruit his failing health, the king visited California in the U.S. cruiser *Charleston* in November 1890. In spite of the best medical attendance he continued to fail, and breathed his last on the 20th of January 1891 in San Francisco. His remains were brought to Honolulu in the *Charleston*, arriving there on the 29th of January, when the decorations for his welcome were suddenly changed into the emblems of mourning. On the same day at noon his sister, the regent, took the oath to maintain the constitution of 1887, and was proclaimed queen, under the title of Liliuokalani.

The history of her short and troubled reign shows that it was her constant purpose to restore autocratic government, and to govern as well as to reign. Passing over minor events, the legislative session of 1892, during which four changes of ministry took place, was protracted to eight months chiefly by her determination to carry through the opium and lottery Bills and to have a cabinet in sympathy with her views in regard to the constitution. Meanwhile she had caused a new constitution to be secretly drawn up, which would practically have transformed the Government from a limited to an absolute monarchy, besides disfranchising a large class of citizens who had voted since 1887. This constitution she undertook to spring upon the country by a *coup d'état*, immediately after proroguing the legislature on the 14th of January 1893. At the critical moment, when her preparations were complete, her ministers shrank from the responsibility of so revolutionary an act, and with difficulty prevailed upon her to postpone the execution of her design. In such undertakings to hesitate is fatal. Again there was an uprising of the conservative part of the community similar to that of 1887. But this time the prevailing opinion condemned all half-way measures, and declared the monarchy to be forfeited by its own act. A third party proposed a regency during the minority of the heir-apparent, Princess Kaiulani, but in her absence this scheme found few supporters. A Committee of Safety was appointed at a public meeting, which proceeded to form a Provisional Government and to reorganize the volunteer military companies, which had been disbanded in 1890. It also called a mass meeting of citizens, which met on the afternoon of the 16th and ratified its action. The U.S. steamer *Boston*, which had unexpectedly arrived from Hilo on the 14th, landed a small force on the evening of the 16th, at the request of the U.S. minister, Mr J. L. Stevens, and a committee of residents, to protect the lives and property of American citizens in case of riot or incendiarism. The next day, the 17th, the Committee of Safety took possession of the Government Building, and issued a proclamation declaring the monarchy to be abrogated, and establishing a Provisional Government, to exist "until terms of union with the United States of America shall have been negotiated and agreed upon." Meanwhile two companies of volunteer troops arrived and occupied the grounds. By the advice of her ministers, and to avoid bloodshed, the queen surrendered under protest, in view of the landing of United States troops, appealing to the Government of the United States to reinstate her in authority. A treaty of annexation was negotiated with the United States during the next month, but it was withdrawn on 9th March 1893 by President Cleveland, who then despatched Mr J. H. Blount of Macon, Georgia, as his special commissioner, to investigate the situation in the Hawaiian Islands. On receiving Mr Blount's report to the effect that the revolution had been accomplished by the aid of the U.S. minister and by the landing of troops from the *Boston*, President Cleveland sent the Hon. A. S. Willis of Kentucky to Honolulu with secret instructions as U.S. minister. Accordingly, Mr Willis, having with much difficulty and delay obtained the queen's promise to grant an amnesty, made a formal demand on the Provisional Government for her reinstatement on the 19th of December 1893. On the 23rd President S. B. Dole, of the Provisional Government, sent a reply to Minister Willis, declining to surrender its authority to the deposed queen. The U.S. Congress declared against any further intervention. On the 30th of May 1894 a convention was held to frame a constitution for the republic of Hawaii, which was proclaimed on the 4th of July following, with S. B. Dole as its first President. Towards the end of the same year a plot was formed to overthrow the republic and to restore the monarchy. A cargo of arms and ammunition from San Francisco was secretly landed at a point near Honolulu, where a company of native royalists were collected 6th January 1895, intending to capture the Government Buildings by surprise that night, with the aid of their allies in the city. A premature encounter with a squad of police alarmed the town and broke up their plans. There were several other skirmishes during the following week, resulting in the capture of the leading conspirators, with most of their followers. The ex-queen, on whose premises a large quantity of arms and ammunition, together with a number of incriminating documents, were found, was arrested and imprisoned for nine months in the former palace. On the 24th of January she formally renounced all claim to the throne and took the oath of allegiance to the republic. The ex-queen and forty-eight others were granted conditional pardons on the 7th of September, and on the following New Year's Day the remaining prisoners were set at liberty.

On the inauguration of President McKinley, in March 1897, negotiations with the United States were resumed, and on the 16th of June a new treaty of annexation was signed at Washington. As its ratification appeared to be uncertain, a joint resolution to the same effect was introduced, which passed the Senate by a vote of 42 to 21 and the House of Representatives by a vote of 209 to 91, and was signed by the President on the 7th of July 1898. The formal transfer of sovereignty took place on 12th August 1898, when the flag of the United States was raised over the Executive Building with impressive ceremonies. The public debt of the republic of Hawaii was assumed by the United States, with a limit of four million dollars. The existing laws of Hawaii were to continue in force until Congress should pass laws organizing the future government of the islands. In 1900 Congress passed an Act, approved by the President 30th April, by which the Territory of Hawaii was organized and a territorial government was established, with its capital at Honolulu. This Act declared all persons who were citizens of the Republic of Hawaii on 12th August 1898 to be citizens of the United States and of the Territory of Hawaii, and provided that the constitution and, except as specially provided, all the laws of the United States not locally

inapplicable should have the same force and effect within the Territory as elsewhere in the United States.

Government. Under this Act the legislature meets biennially, and consists of a Senate of 15 members holding office for four years, and a House of Representatives of 30 members holding office for two years. In order to vote for representatives or senators, the elector must be a male citizen of the United States who has attained the age of twenty-one years, has resided in the Territory not less than one year preceding, and is able to speak, read, and write the English or Hawaiian language. No person is allowed to vote who is in the Territory by reason of being in or attached to the army or navy. The executive power is vested in a governor, appointed by the President and holding office for four years. He must be not less than thirty-five years of age and a citizen of the Territory. The secretary of the Territory is appointed in like manner for the same length of term. The governor appoints, by and with the consent of the Senate of the Territory, an attorney-general, treasurer, commissioner of public lands, commissioner of agriculture and forestry, superintendent of public works, superintendent of public instruction, auditor and deputy auditor, surveyor, high sheriff, members of the board of health, commissioners of public instruction, board of prison inspectors, board of registration, and inspectors of election, &c. All such officers are appointed for four years except the commissioners of public instruction and the members of the said boards, whose terms are as provided by the laws of the Territory; all must be citizens of the Territory. The judicial power of the Territory is vested in one supreme court, circuit courts, and such inferior courts as the legislature may establish. One delegate is elected to the United States House of Representatives, and there is also established a United States district court. The Territory is also constituted an internal-revenue district and a customs district. The Act further provides that no Chinese labourer shall be allowed to enter any state, territory, or district of the United States from the Hawaiian Islands; and the Act of Congress of 26th February 1885, "To prohibit the importation and migration of foreigners and aliens under contract or agreement to perform labour in the United States, its territories, and the District of Columbia," and the amending and supplementing Acts, are extended to Hawaii.

The President appointed Sanford B. Dole Governor of the Territory, and on 14th June 1900 the new territorial government was formally instituted. The first elected legislature met on the 20th February 1901. The majority proved hostile to the Governor, passed a resolution asking the President to remove him, and adjourned without making appropriations. An extra session in May was no more harmonious. Matters went so far that the Governor was brought before a grand jury; but no indictment was found, and the President declined to remove him.

Immigration and Population.—The pressing demand for labour created by the Reciprocity Treaty has led to great changes in the population of the Hawaiian Islands. It has been the policy of the Government to assist immigrants from widely different countries, not only as labourers but also as prospective citizens. In the year 1877 arrangements were made for the importation of Portuguese families from the Azores and Madeira, and during the next ten years about 7000 of these people were brought to the islands. Others have since been added to their number, and their natural increase has been very rapid. In 1900 the total number of Portuguese in the islands, including those born there, was not far from 16,000, about 2400 of whom were employed in sugar plantations. They have shown themselves to be industrious, thrifty, and law-abiding. Persistent efforts have also been made to introduce Polynesian islanders, as being of a cognate race with the Hawaiians, but the results have been wholly unsatisfactory. About 2000 of these people, mainly from the Gilbert Islands, were brought in at the expense of the Government between 1878 and 1884; but they did not give satisfaction either as labourers or as citizens, and most of them have been returned to their homes. There has never existed any treaty or labour convention between the Government of Hawaii and the empire of China. In early days a limited number of Chinese settled in the islands, intermarried with the natives, and by their industry and economy were generally prosperous. About 750 of them were naturalized under the monarchy. The first importation of Chinese labourers into the country took place in 1852. In 1878 the number of Chinese had risen to 5916. During the next few years there was a steady influx of Chinese free immigrants, which finally reached alarming proportions. In the spring of 1881 the Hawaiian Government was obliged to send a dispatch to the Governor of Hong Kong to stop this invasion. Again, in April 1883, it was suddenly renewed, and within twenty days five steamers arrived from Hong Kong bringing 2253 Chinese passengers, followed the next month by 1100 more, with the news that several thousand more were ready to embark. Accordingly the Hawaiian Government sent another dispatch to the Governor of Hong Kong, refusing to admit any further immigration of male Chinese from that port. Various regulations restricting Chinese immigration were enacted from time to time, until in 1886 the landing of any Chinese passenger without a passport was prohibited. The number of Chinese in the islands had then risen to 21,000, and in 1900 they were estimated to be 27,000, of whom 6000 were employed on sugar plantations. The consent of the Japanese Government to the emigration of its subjects to Hawaii was obtained with difficulty in 1884, and in 1886 a labour convention was ratified. Since then the increase of the Japanese element in the population has been constant and rapid. It rose from 116 in 1884 to 12,360 in 1890, and 24,400 in 1896. In 1900 it was 61,111, of whom 26,000 were employed in sugar plantations. They have for the most part been recruited from the lowest classes in Japan. Unlike the Chinese, they show no inclination to intermarry with the Hawaiians. The effect of making Hawaii a territory of the United States was to put an end to all assisted immigration, of whatever race, and to exclude all Chinese labourers. But under the recent treaty between the United States and Japan there is nothing to limit the free immigration of Japanese, and several companies have been formed to promote it. The system of contract labour, which was abolished by Act of Congress in 1900, concerned but a small minority of the labourers other than Japanese. Various methods of co-operation or profit-sharing are in successful operation on some plantations.

The excessive preponderance of males over females in Asiatic immigration constitutes a serious menace to the morals and health of the commonwealth. The decrease of the aboriginal population has still continued, from 44,088 in 1878 to 40,014 in 1884, 34,436 in 1890, and 31,019 in 1896, the rate of decrease being about $1\frac{5}{10}$ per cent. a year. At the same time the part-Hawaiians, the offspring of intermarriage between Hawaiian women and men of other races, have been constantly increasing from 3420 in 1878 to 4218 in 1884, 6186 in 1890, and 8485 in 1896. All these facts point to the gradual extinction of the full-blooded Hawaiians, and the absorption of the remnant of the race by the European and Asiatic population. The scourge of leprosy, which is almost confined to the native Hawaiians, is being gradually extinguished by segregation. The number of cases at the Molokai settlement has been reduced from 1200 to about 900.

The population in 1900 was 154,001, distributed as follows:—Hawaii, 46,843; Kauai and Niihau, 20,734; Maui, 25,416; Molokai and Lanai, 2504; Oahu, 58,504.

Of the total population, 106,369 (69·1 per cent.) were males and 47,632 (30·9 per cent.) females; 63,221 (41·1 per cent.) were native-born and 90,780 (58·9 per cent.) foreign-born; 66,890 (43·4 per cent.) were white and 87,111 (56·6 per cent.) were coloured. Under the heading white are classed 37,656 Hawaiians or part-Hawaiians, 28,819 Caucasians, and 415 South Sea Islanders. The class coloured included 25,767 Chinese, 61,111 Japanese, and 233 persons of negro descent. Of the white population, 54,141 were native-born and 12,749 (8·3 per cent. of total population) foreign-born, largely Portuguese. The number of males of voting age (21 years and over) was 79,607, of whom 13,064 were native-born and 66,543 (83·6 per cent.) were foreign-born, principally Chinese and Japanese; and 60,031 (75·4 per cent.) were coloured, of whom 93 were persons of negro descent and the remainder Chinese and Japanese. Of the total number of males of voting age, 27,363 were illiterate (unable to write), of whom 26,641 were foreign-born and 24,028 were coloured (including 16,723 Japanese, 7276 Chinese, and 29 negroes). The urban population in 1900, classing as such all persons in cities of 8000 inhabitants or over (*i.e.*, in Honolulu), was 39,306, or 25·5 per cent. of the total population—which was exactly the same percentage as in 1890.

Land.—The total area of the inhabited islands slightly exceeds four million acres. The tenure by which these lands were held before 1840 was strictly feudal, having probably been evolved out of a prehistoric communal system. In the great division which took place in 1848, and which forms the foundation of land titles, about one million acres were set apart for the king and his successors, a million and a half acres for the Government, and an equal amount for the several chiefs, while the common people were granted fee simple titles for their house lots and the pieces of land which they had cultivated for themselves. As the chiefs generally ran into debt, and died in many cases without heirs, their lands have largely passed into the hands of foreigners. About half of the original Government land has been sold. The census of 1896 showed that there were at that time 3995 landowners of pure Hawaiian blood out of 31,019 men, women, and children.

At the abolition of the monarchy in 1893 the crown domains were declared to be public lands, and, together with the other Government lands, were turned over to the United States. Taken together, these lands now comprise a million and three-quarter acres, valued at seven and a half million dollars. A carefully-drawn Land Act, embodying many of the provisions of the New Zealand system, was passed in 1895, and was to be continued in force by the Cullom Bill. It was intended to promote the subdivision of the Government land into small holdings for actual settlers, and to discourage mere speculators. The crown lands, which were made by law inalienable in 1865, have hitherto been held for the most part under long leases. As these leases expire from time to time, it is the policy of the Government to break up gradually the large holdings into homesteads, and thus to encourage the growth of an agricultural population.

Commercial Progress.—Under the stimulus of the Reciprocity Treaty, the production of sugar, the principal staple of the islands, had increased twenty-fold in 1897, and in 1900 the value was $19,254,773. In 1900 there were 395 manufacturing establishments, with a total capital of $11,541,655, employing 4587 hands, and producing goods valued at $24,992,068. The total value of the domestic exports of the islands rose from $1,835,382 in 1875 to $22,628,741 in 1899; and the total value of the imports rose from $1,682,471 to $19,059,605·79, including $2,990,000 in specie. The number of vessels employed in the foreign carrying trade in 1898 was 481.

During 1899, 655 merchant vessels (of which 447 were American), with a tonnage of 786,842, entered at the ports of Hawaii. During the same year, 32,725 passengers (of whom 4705 were from San Francisco and 27,073 from China and Japan) arrived at Honolulu, and 9065 passengers departed (of whom 4011 sailed for San Francisco and 4398 to China and Japan). From 1843 to 1900 (14th June) inclusive the imports of Hawaii amounted to $184,278,309 and the exports to $286,483,219. During the year ending 30th June 1901 the imports of Hawaii amounted to $2,835,278 and the exports to $120,211—of course exclusive of commerce with the United States. During the same period the merchandise shipped from Hawaii to the United States amounted to $27,903,058, of which a part, valued at $4,293,009, was carried in American steam vessels, and the balance, valued at $23,610,049, in American sailing vessels.

Public Revenue.—The total revenue for the biennial period rose from $877,791 in 1874–75 to $5,913,720 in 1898–99. This latter amount was derived from the following sources:—Customs, $2,192,604; direct taxation, $1,879,935; postal bureau, $206,563; public lands, $315,256; licences, $333,994; besides sums received from fines and penalties, fees, waterworks, &c. The total expenditure for 1898–99 was, from current receipts, $4,740,005, and from loan fund for public improvements, $756,504. The total national debt, January 1900, was $4,890,351.

Material Improvements.—Under the monarchy much was done for the improvement of the city of Honolulu, but the outlying districts were neglected and the country roads were mere bridle-paths. Among the public improvements executed since 1878 may be mentioned the palace, now styled the Executive Building, erected in 1878–81 at a cost of $350,000; the marine railway, completed in 1882, at a cost of $90,000; and the police station, built in 1885, at a cost of $91,000. Lighthouses were placed at Barber's Point and at the south-west point of Molokai in the same year. Under the republic great attention has been paid to roads, and more has been accomplished in this direction since 1890 than during the entire previous history of the country. The entrance to the harbour of Honolulu was deepened to 30 feet in 1892, and a complete system of sewerage for the city was begun. The United States Congress has set aside $100,000 for deepening the entrance of Pearl Lochs, 7 miles west of Honolulu, which will open for commerce one of the finest harbours in the Pacific Ocean. Private enterprise has done still more to develop the resources of the islands and to improve the communications. The number of inter-island steamers has increased from two to twenty-two, besides twenty inter-island sailing vessels. The first railway built in the islands was the Kahului railway on Maui, which was begun in 1879, and is 15 miles long. The Kohala railway, which was built two years later, is 20 miles long. The Oahu railway, begun in 1888, has been completed from Honolulu around the western and northern sides of the island to Kahuku, a distance of 70 miles. Street tramways run in Honolulu. Each of the four principal islands is now encircled by telephone lines.

Agricultural Progress.—The immense increase in the production of sugar is due not only to the increase of the area planted with cane, but also to the scientific use of fertilizers, to more extensive irrigation, to improved machinery in mills, and to improved processes for the treatment of the juice. In several localities extensive irrigation canals have been constructed, which have brought into cultivation large tracts of land which had formerly lain barren. The first artesian well in the islands was bored at Honouliuli in July 1879, and met with unexpected success. Since then more than two hundred artesian wells have been sunk around the island of Oahu. Many of the plantations are now supplied with water for irrigation by pumping works, drawing their supply from wells. The crop of sugar has risen in some plantations to 10 and even 14 tons per acre, two crops being taken off in about three years. The average annual production for all the islands is about 5 tons per acre. The total number of labourers employed in the sugar plantations is about 40,000. The cultivation of rice, which was begun in 1860 with Carolina seed, has passed entirely into the hands of the Chinese.

The annual production is estimated to be about ten million pounds, most of which is consumed in the islands. The Kona coffee has established a reputation for quality equal to that of any in the world, and readily brings twice the price of the Brazilian product. Its culture is particularly adapted to farmers of moderate means, and tends to promote the multiplication of homesteads and the employment of a better class of labour. In 1898, 733,285 pounds of coffee were exported, valued at $132,347. The bananas exported in 1899 were valued at $84,268. There are many other kinds of fruits, as well as of fibre plants, such as sisal, ramie, &c., which can be successfully cultivated in the islands.

Educational Progress.—Education is universal, compulsory, and free. Every child between the ages of six and fifteen must attend either a public school or a duly authorized private school. Consequently the percentage of illiteracy is extremely low. English is by law the medium of instruction in all schools, both public and private, although other languages may be taught in addition. The schools are in session forty weeks during the year. The school system is essentially American in its text-books and its methods. A normal school has been established at Honolulu, with a practice school attached to it. The Honolulu High School is justly the pride of the department, both for the beauty of its buildings and grounds and the excellence of its work. Industrial training is as yet in its infancy. The Lahainaluna Seminary, founded in 1831, furnishes instruction to Hawaiian boys in agriculture, carpentry, printing, and mechanical drawing. The boys in the Reformatory School are taught useful trades. The teaching of sewing in the public schools has met with great success, and a simple form of the Swedish Sloyd has been introduced into many of the schools. But the best instruction of this kind is furnished by the independent schools, among which the Kamehameha Schools take the first place. They were founded by the late Mrs Bernice Pauahi Bishop, the last lineal descendant of Kamehameha I., who left her extensive landed estate in the hands of trustees for their support. They furnish a good manual and technical training to Hawaiian boys and girls, in addition to a primary and grammar school course of study, and exert a strong religious influence. There are six boarding schools for Hawaiian girls, supported by private resources. The most advanced courses of study are offered by Oahu College, which occupies a beautiful site east of Honolulu. It is well equipped with buildings and apparatus, and has an endowment of about $300,000.

During the biennial period ending 31st December 1899 the expenditure of the Hawaiian Government for the support of public schools was $569,188, of which sum $428,862 was paid for teachers' salaries. The average salary paid to public school teachers is $645 per annum. In 1899 there were 142 Government schools, with 344 teachers and 11,436 pupils; 55 independent schools, with 200 teachers and 4054 pupils, giving a total of 197 schools, with 544 teachers and 15,490 pupils. Of these pupils 5043 were Hawaiian, 2721 part-Hawaiian, 1314 Chinese, 1141 Japanese, 2767 Portuguese, and 2504 other foreigners. In 1900 the number of persons of school age (5 to 20 years inclusive) was 33,774, of whom 8489 (25·1 per cent.) were foreign-born.

Religion.—There are Protestant, Roman Catholic, and Mormon teachers, and recently Buddhist priests have been sent from Japan. The Roman Catholics comprise the bulk of the Portuguese population and about one-third of the natives. Perhaps three-fifths of the Hawaiians, and nearly all of British, American, or Northern European race, are Protestants. There are flourishing Protestant missions among the Portuguese, Chinese, and Japanese. The Mormons claim over 4000 adherents, nearly all native Hawaiians.

(W. D. A.)

Haweis, Hugh Reginald (1838–1901), English preacher and writer, was born at Egham, Surrey, 3rd April 1838, his father and grandfather having both been clergymen. On leaving Trinity College, Cambridge, he took orders in the Church of England and held various curacies in London, becoming in 1866 incumbent of St James's, Marylebone. His unconventional methods of conducting the service, combined with his dwarfish figure and lively manner, soon attracted crowded congregations, particularly of people who liked a little "sensation." He married Miss M. E. Joy in 1866, and both he and Mrs Haweis (died 1898) contributed largely to periodical literature and travelled a good deal abroad. Mr Haweis was much interested in music, and wrote books on violins and on church bells, besides contributing an article to the 9th edition of the *Encyclopædia Britannica* on bell-ringing. As a lecturer also he was very successful, in America as well as in England. His best-known book was *Music and Morals;* and for a time he was editor of *Cassell's Magazine.* He died on 29th January 1901.

Hawick, a parliamentary burgh (Border group) of Roxburghshire, Scotland, on the Teviot, 53 miles south-south-east of Edinburgh by rail. There are now 20 hosiery factories and 7 tweed merchants, owning several spinning mills. Twelve of the hosiery factories and 9 of the tweed factories each employ several hundred women. About 200 hand-frames for knitting are still in use; iron-founding, engineering, and dyeing are carried on. There are five large nursery gardens. Great lamb, sheep, and cattle sales are held periodically. Recent erections are a cottage hospital, municipal buildings (including a free library), and a new post office; there is also a science and art institute. The academy furnishes both secondary and technical education. Population (1881), 16,184; (1901), 17,303.

Hawkins, Cæsar Henry (1798–1884), British surgeon, son of the Rev. E. Hawkins and grandson of the Sir Cæsar Hawkins who was serjeant-surgeon to Kings George II. and George III., was born 19th September 1798, educated at Christ's Hospital, and entered St George's Hospital, London, in 1818 (M.R.C.S. 1821, F.R.C.S. 1843). He was surgeon to the hospital from 1829 to 1861, and in 1862 was made serjeant-surgeon to Queen Victoria. He was president of the College of Surgeons in 1852, and again in 1861; and he delivered the Hunterian oration in 1849. His success in complex surgical cases gave him a great reputation. For long he was noted as the only surgeon who had succeeded in the operation of ovariotomy in a London hospital. This occurred in 1846, when anæsthetics were unknown. He did much to popularize colotomy. A successful operator, he nevertheless was attached to conservative surgery, and was always more anxious to teach his pupils how to save a limb than how to remove it. He reprinted his contributions to the medical journals in two volumes, 1874, the more valuable papers being on *Tumours, Excision of the Ovum, Hydrophobia and Snake-bites, Stricture of the Colon,* and *The Relative Claims of Sir Charles Bell and Majendie to the Discovery of the Functions of the Spinal Nerves.* He died 20th July 1884. His brother, Edward Hawkins (1789–1882), was the well-known Provost of Oriel, Oxford, who played so great a part in the Tractarian movement.

Hawkshaw, Sir John (1811–1891), English engineer, was born in Yorkshire in 1811. What scholastic education he received was imparted to him at Leeds

Grammar School, but his real education was gained in the school of practical experience. Before he was twenty-one he had been engaged for six or seven years in railway engineering and the construction of roads in his native county, and in the year of his majority he obtained an appointment as engineer to the Bolivar Mining Association in Venezuela. But the climate there was more than his health could stand, and in 1834 he was obliged to return to England. He soon obtained employment under Jesse Hartley at the Liverpool docks, and subsequently was made engineer in charge of the railway and navigation works of the Manchester, Bury, and Bolton Canal Company. In 1845 he became chief engineer to the Manchester and Leeds Railway, and in 1847 to its successor, the Lancashire and Yorkshire Railway, for which he constructed a large number of branch lines. In 1850 he removed to London and began to practise as a consulting engineer, at first alone, but subsequently in partnership with Harrison Hayter. In that capacity his work was of an extremely varied nature, embracing almost every branch of engineering. He retained his connexion with the Lancashire and Yorkshire Company until his retirement from professional work in 1888, and was consulted on all the important engineering points that affected it in that long period. In London he was responsible for the Charing Cross and Cannon Street railways, together with the two bridges which carried them over the Thames; he was engineer of the East London Railway, which passes under the Thames through Brunel's well-known tunnel; and jointly with Sir J. Wolfe Barry he constructed the section of the Underground Railway which completes the "inner circle" between the Aldgate and Mansion House stations. In addition, many railway works claimed his attention in all parts of the world—Germany, Russia, India, Mauritius, &c. One noteworthy point in his railway practice was his advocacy, in opposition to Robert Stephenson, of steeper gradients than had previously been thought desirable or possible, and so far back as 1838 he expressed decided disapproval of the maintenance of the broad gauge on the Great Western, because of the troubles he foresaw it would lead to in connexion with future railway extension, and because he objected in general to breaks of gauge in the lines of a country. The construction of canals was another branch of engineering in which he was actively engaged. In 1862 he became engineer of the Amsterdam ship-canal, and in the succeeding year he may fairly be said to have been the saviour of the Suez Canal. About that time the scheme was in very bad odour, and the Khedive determined to get the opinion of an English engineer as to its practicability, having made up his mind to stop the works if that opinion was unfavourable. Hawkshaw was chosen to make the inquiry, and it was because his report was entirely favourable that M. de Lesseps was able to say at the opening ceremony that to him he owed the canal. As a member of the International Congress which considered the construction of an interoceanic canal across Central America, he thought best of the Nicaraguan route, and privately he regarded the Panama scheme as impracticable at a reasonable cost, although publicly he expressed no opinion on the matter and left the Congress without voting. Sir John Hawkshaw also had a wide experience in constructing harbours (*e.g.*, Holyhead) and docks (*e.g.*, Penarth, the Albert Dock at Hull, and the south dock of the East and West India Docks in London), in river-engineering, in drainage and sewerage, in water-supply, &c. He was engineer, with Sir James Brunlees, of the original Channel Tunnel Company from 1872, but many years previously he had investigated for himself the question of a tunnel under the Strait of Dover from an engineering point of view, and had come to a belief in its feasibility, so far as that could be determined from borings and surveys. Subsequently, however, he became convinced that through railway communication with the Continent would not be to the advantage of Great Britain, and thereafter would have nothing to do with the project. He was also engineer of the Severn Tunnel, which, from its magnitude and the difficulties encountered in its construction, must rank as one of the most notable engineering undertakings of the 19th century. He died at his London residence on 2nd June 1891. (H. M. R.)

Hawksley, Thomas (1807–1893), English engineer, was born on 12th July 1807, at Arnold, near Nottingham. He was at Nottingham Grammar School till the age of fifteen, but was indebted to his private studies for his knowledge of mathematics, chemistry, and geology. In 1822 he was articled to an architect in Nottingham, subsequently becoming a partner in the firm, which also undertook engineering work; and in 1852 he removed to London, where he continued in active practice till he was well past eighty. His work was chiefly concerned with water and gas supply and with main-drainage. Of water-works he used to say that he had constructed 150, and a long list might be drawn up of important towns that owe their water to his skill, including Liverpool, Sheffield, Leicester, Leeds, Derby, Darlington, Oxford, Cambridge, and Northampton in England, and Stockholm, Altona, and Bridgetown (Barbados) in other countries. To his native town of Nottingham he was water engineer for fifty years, and the system he designed for it was noteworthy from the fact that the principle of constant supply was adopted for the first time. The gas-works at Nottingham, and at many other towns for which he provided water supplies, were also constructed by him. He designed main-drainage systems for Birmingham, Worcester, and Windsor, among other places, and in 1857 he was called in, together with Bidder and Bazalgette, to report on the best solution of the vexed question of a main-drainage scheme for London. In 1872 he was president of the Institution of Civil Engineers—an office in which his son succeeded him, in 1901. He died at his residence on Campden Hill, Kensington, on 23rd September 1893.

Haworth, parish and village, in the Keighley division of the West Riding of Yorkshire, England, 10 miles north-west of Bradford, with a station on a branch of the Midland Railway. Since 1894 it has been governed by an urban district council. The Reverend Patrick Brontë was incumbent here for forty-one years, and a memorial near the west window of St Michael's Church bears his name and the names of his gifted daughters upon it. The grave of Charlotte and Emily Brontë is also marked by a brass. In 1895 a museum was opened by the Brontë Society. A cemetery was formed in 1891. Population of the parish and urban district (1901), 7492.

Hay, John (1838– ——), American statesman and author, was born at Salem, Indiana, on the 8th of October 1838. He graduated from Brown University in 1858. Admitted to the bar in Springfield, Illinois, in 1861, he was at once selected by President Lincoln as assistant private secretary, in which capacity he served till the President's death. From 1865 to 1870 Mr Hay filled various posts in the U.S. legations at Paris, Vienna, and Madrid, and later, under President Hayes, he was first assistant Secretary of State (1879–81). In the interval he was for a time an editorial writer on the New York *Tribune*, and he also produced his *Pike County Ballads* (1871) and *Castilian Days* (1871). His most important

literary work was a monumental biography of Lincoln in collaboration with Mr Nicolay, which was published in book form in 1890. Upon the inauguration of President McKinley in 1897, Mr Hay was appointed ambassador to Great Britain, from which post he was transferred in 1898 to that of Secretary of State. Thus it fell to him to direct the peace negotiations with Spain after the war of 1898, and to secure American interests in the imbroglio caused by the Boxers in China. When President McKinley was murdered, and President Roosevelt succeeded, Mr Hay remained in office. It was largely due to his tact and good management, in concert with Lord Pauncefote, the British Ambassador, that negotiations for abrogating the Clayton-Bulwer Treaty and making a new treaty with Great Britain regarding the Isthmian Canal were successfully concluded at the end of 1901.

Haydock, parish and township, in the Newton division of Lancashire, England, 7 miles north-west of Warrington, 3 miles from Newton-in-Makerfield, station on the London and North-Western Railway. Since 1894 it has been governed by an urban district council. The church of St James's was rebuilt in 1891, a handsome Congregational chapel has been erected, and there are a cottage hospital and a large private lunatic asylum. There are extensive coal mines in the district. Population of the urban district (1901), 8575.

Hayes, Rutherford Birchard (1822–1893), nineteenth President of the United States, was born in Delaware, Ohio, 4th October 1822. He received his first education in the common schools, then passed through the ordinary academic course at Kenyon College, and was a student at the law school of Harvard University from 1843 to 1845. He practised law, first at Upper Sandusky and then at Cincinnati, Ohio, where he won a very respectable standing. As a politician he supported the Whig party, but, having always cherished anti-slavery sentiments, he joined the Republican party in 1854. After the breaking out of the Civil War the governor of Ohio, on 7th June 1861, appointed him a major of a volunteer regiment, and in July he was ordered to West Virginia for active service. His military career was uncommonly creditable, and he attained by his meritorious conduct the rank of brevet major-general. While still in the field he was elected a member of Congress, and took his seat in December 1865. He was re-elected in 1866, and supported the reconstruction measures advocated by his party. In 1867 he was elected governor of Ohio, and was re-elected in 1869. In 1873 he transferred his residence from Cincinnati to Fremont, a small town in the northern part of Ohio, his intention being to withdraw from public life; but in 1875 the Republican party in Ohio once more selected him as its candidate for the governorship. He accepted the charge with great reluctance. The opposition party, the Democrats, adopted a platform declaring in favour of indefinitely enlarging the volume of the irredeemable paper currency which the Civil War had left behind it. Hayes stoutly advocated the speediest practicable resumption of specie payments, and carried the election. The "sound-money campaign" in Ohio having attracted the attention of the whole country, Hayes was marked out as a candidate for the Presidency, and he obtained the nomination of the Republican National Convention of 1876. The candidate of the Democratic opposition, Samuel J. Tilden, by his reputation as a statesman and a reformer of uncommon ability drew many Republican votes. An excited controversy having arisen about the result of the balloting in the States of South Carolina, Florida, and Louisiana, to allay a crisis dangerous to public peace the two parties in Congress agreed to pass an Act referring all contested election returns to an extraordinary commission. This commission decided each contest by eight against seven votes in favour of the Republican candidates, and Mr Hayes was accordingly declared duly elected.

During his administration President Hayes devoted his efforts mainly to civil service reform, resumption of specie payments, and the pacification of the States recently in rebellion. In order to win the co-operation of the white people in the South in maintaining peace and order, he put himself in communication with their leaders. He then withdrew the Federal troops which since the Civil War had been stationed at the southern State capitals. An end was thus made of the so-called "carpet-bag governments" conducted by Republican politicians from the North, some of which were very corrupt, and had been upheld mainly by the Federal forces. This policy found much favour with the people generally, but displeased many of the Republican politicians, because it loosened the hold of the Republican party upon the Southern States. Though it did not secure to the negroes sufficient protection in the exercise of their political rights, it did much to extinguish the animosities still existing between the two sections of the Union, and to promote the material prosperity of the South. President Hayes endeavoured in vain to induce Congress to appropriate money for a Civil Service Commission; and whenever he made an effort to restrict the operation of the traditional "spoils system," he met the strenuous opposition of a majority of the most powerful politicians of his party. Nevertheless the system of competitive examinations for appointments was introduced in some of the great executive departments in Washington, and in the custom-house and the post-office in New York. Moreover, he ordered that "no officer should be required or permitted to take part in the management of political organizations, caucuses, conventions, or election campaigns," and that "no assessment for political purposes on officers or subordinates should be allowed"; and he removed from their offices the heads of the post-office in St Louis and of the custom-house in New York—influential party managers—on the ground that they had misused their official positions for partisan ends. While these measures were of limited scope and effect, they served greatly to facilitate the more extensive reform of the civil service which subsequently took place. Although the resumption of specie payments had been provided for to begin at a given time by the Resumption Act of January 1875, opposition to it did not cease. A Bill went through both Houses of Congress providing that a silver dollar should be coined of the weight of 412½ grains, to be full legal tender for all debts and dues, public and private, except where otherwise expressly stipulated in the contract. President Hayes returned this Bill with his veto, but the veto was overruled in both Houses of Congress. Meanwhile, however, the preparations for the return to specie payments were continued by the Administration with unflinching constancy, and on 1st January 1879 specie payments were resumed without difficulty. None of the evils predicted appeared. A marked revival of business and a period of general prosperity ensued. In his annual message of 1st December 1879 President Hayes urged the suspension of the silver coinage and also the withdrawal of United States legal tender notes, but Congress failed to act upon the recommendation. His Administration also did much to ameliorate the condition of the Indian tribes and to arrest the spoliation of the public forest lands.

Although President Hayes was not popular with the professional politicians of his own party, and was exposed to bitter attacks on the part of the Democratic opposition

on account of the cloud which hung over his election, his conduct of public affairs gave much satisfaction to the people generally. In the Presidential election of 1880 the Republican party carried the day after an unusually quiet canvass, a result largely due to popular contentment with the then existing state of public affairs. On 4th March 1881 President Hayes retired to his home at Fremont, Ohio. Various universities and colleges conferred honorary degrees upon him. His remaining years he devoted to active participation in philanthropic enterprises. He died after a short illness, 17th January 1893.

See *Life, Public Services, and Select Speeches of Rutherford B. Hayes*, by JAMES GRAY HOWARD, Cincinnati, 1876. *Life of R. B. Hayes*, by WILLIAM D. HOWELLS, New York, 1876; and by RUSSELL H. CONWELL, Boston, 1876. (C. S.)

Hayti, or SANTO DOMINGO, a West Indian island, comprising the two republics of Hayti and Santo Domingo, or the Dominican Republic. I. THE HAYTI REPUBLIC has an area of about 10,000 square miles, with a population of about 800,000. There are a President and two Chambers, the members of which hold office according to a Constitution dating from 1889. The army numbers about 7000 men, nominally, and the republic owns six third-class cruisers. Owing to the excessive customs duties, caused by the financial difficulties of the republic, coupled with the lack of capital and enterprise, trade has for some years been in a very depressed condition. At the end of 1899 the liabilities of the republic amounted to 19,075,733 dollars gold and 9,372,183 dollars paper (*gourdes*), as compared with a total (gold and paper) of 15,261,557 dollars in 1892. The amount of duties received from exports in 1899 was 2,815,902 dollars gold, as compared with 3,442,114 dollars in 1895; the import duties in the same years amounting in Haytian currency to 2,618,869 dollars and 4,107,989 dollars respectively. Imports were valued at 6,232,335 dollars in 1895, and exports at 13,788,562 dollars. Though showing a decided tendency to decline in 1896, they were about the same in 1897. Owing to the fall of prices in Europe and America, small coffee planters find it almost impossible, with the heavy export duties, to earn a living by this industry, and are beginning instead to raise plantains, yams, bananas, &c. The other chief products are logwood, mahogany, honey, wax, hides, and goatskins. Owing to the depression of trade, imports are confined to bare necessaries — the cheapest sort of dry goods and fancy goods, empty bags, lumber, matches, &c. Flour, salt pork, salt beef, codfish, lard, butter, and similar provisions continue to be imported, but in reduced quantities. Unable to purchase foreign rice, the natives now grow their own supplies. Considerable attention is devoted to the cultivation of tobacco, for which, as well as for sugar-cane, soil and climate are both admirably adapted. Indeed, the country is one of the most fertile in the world, and it is supposed to possess, in addition, valuable deposits of coal, copper, mercury, and other minerals. A railway from Cap-Haïtien to La Grande Rivière (15 miles) was completed in 1900, and a concession has been granted for branch lines to Quanaminte (35 miles) and Limbé (19 miles). In 1900 a further concession was granted for a line from Port-au-Prince to Salt Lake (50 miles). This railway is intended to connect ultimately the capitals of Hayti and the Dominican Republic. The depression in trade rather increased in 1899, but in the spring of 1900 a proposal was brought forward for the consolidation of the debt, the creditors relinquishing the guarantee of a percentage of the revenue collected, and accepting a gold-bearing bond, augmented 10 per cent. in value, with interest at the rate of 1 per cent. in gold per month, and payable in fourteen years, the expectation being that the consequent great revival of trade on the conclusion of this arrangement would enable the Government within that period to meet amply their obligations. Still it is to be feared that the country can be saved from ultimate disaster only by the more direct intervention and guidance of the white man. The religion is nominally Roman Catholic, but the bulk of the black population are becoming more and more demoralized by secret addiction to pagan practices, including Vaudoux worship, the horrid rites of which imply human sacrifice. The chief towns are Port-au-Prince (61,000), Cap-Haïtien (29,000), Les Cayes (25,000), Gonaives (18,000), and Port de Pain (10,000). They are practically stationary as regards all signs of improvement. II. SANTO DOMINGO, OR THE DOMINICAN REPUBLIC, with an area of about 20,000 square miles, has a population of about 500,000. Government is in the hands of a National Congress of 24 Deputies, a President with executive power elected by an electoral college, and an administrative Ministry appointed by the President. For several years this part of the island has been in a very perturbed political condition, and this culminated in July 1899 in the assassination of President Heureaux. The incoming Government found it necessary to demonetize the paper currency, and the inconvenience caused by this measure to the foreign merchants in the country, who are the chief holders of the paper, was but slightly remedied (October 1900) by certain temporary expedients. The revenue in 1898 amounted to 1,550,294 dollars gold. The foreign debt is about £4,350,000, exclusive of arrears of interest, and the internal about 2,850,000 dollars gold and 10,125,000 dollars silver. There is a small army, and the republic owns three small gunboats. The total value of the imports in 1897 was 1,702,568 dollars gold, and of the exports 4,675,939 dollars; and in 1899 the values were 1,669,994 dollars and 4,166,617 dollars. The sugar-cane is being more and more cultivated, there being now eighteen large plantations. Tobacco, coffee, bananas, and cocoa are the other chief products. Large quantities of mahogany, cedar, and satinwood are also exported; and other exports are honey, wax, gums, hides, lignum vitæ, and logwood. There are deposits of iron, gold, copper, salt, and other minerals, but no attempt has been made to exploit them. In 1899 162 vessels of 157,106 tons entered the port of Puerto Plata. Internal communication is mostly of a primitive kind, and there is a lack of good roads. The capital is Santo Domingo, with a population of about 25,000. A railway extends from Sanchez, on the bay of Samaná, to La Vega (62 miles), and further extensions are in progress or projected.

See *Where Black Rules White*, by HESKETH PRICHARD. London, 1900.

Hayward, Abraham (1801–1884), English man of letters, son of Joseph Hayward, of an old Wiltshire family, was born at Wilton, near Salisbury, on 22nd November 1801. After education at Blundell's School, Tiverton, he entered the Inner Temple in 1824, and was called to the bar in June 1832. He took part as a Conservative in the discussions of the London Debating Society, where his opponents were Roebuck and John Stuart Mill. The editorship of the *Law Magazine; or, Quarterly Review of Jurisprudence*, which he held from 1829 to 1844, brought him into connexion with John Austin, G. Cornewall Lewis, and such foreign jurists as Savigny, whose tractate on contemporary legislation and jurisprudence he rendered into English. In 1833 he travelled abroad, and on his return printed privately a

translation of Goethe's *Faust* into English prose (pronounced by Carlyle to be the best version extant in his time). A second and revised edition was published after another visit to Germany in January 1834, in the course of which Hayward met Tieck, Chamisso, De La Motte Fouqué, Varnhagen von Ense, and Madame Goethe. In 1878 he contributed the rather colourless volume on Goethe to Blackwood's Foreign Classics. A successful translation was in those days a first-rate credential for a reviewer, and Hayward began contributing to the *New Monthly*, the *Foreign Quarterly*, the *Quarterly Review*, and the *Edinburgh Review*. His first successes in this new field were won in 1835–36 by articles on Walker's "*Original*" and on "Gastronomy." The essays were reprinted to form one of his best volumes, *The Art of Dining*, in 1852. In February 1835 he was elected to the Athenæum Club under Rule II., and he remained for nearly fifty years one of its most conspicuous and most influential members. He was also a subscriber to the Carlton, but ceased to frequent it when he became a Peelite. At the Temple, Hayward, whose reputation was rapidly growing as a connoisseur not only of a bill of fare but also (as Swift would have said) of a bill of company, gave *recherché* dinners, at which ladies of high rank and elegance appreciated the wit of Sydney Smith and Theodore Hook, the dignity of Lockhart and Lyndhurst, and the oratory of Macaulay. At the Athenæum and in political society he to some extent succeeded to the position of Croker. He and Macaulay were commonly said to be the two best-read men in town. Hayward got up every important subject of discussion immediately it came into prominence, and concentrated his information in such a way that he habitually had the last word to say on a topic. When Rogers died, or when *Vanity Fair* was published, when the *Greville Memoirs* was issued, or a revolution occurred on the Continent, Hayward, whose memory was as retentive as his power of accumulating documentary evidence was exhaustive, wrote an elaborate essay on the subject for the *Quarterly* or the *Edinburgh*. He followed up his paper by giving his acquaintances no rest until they either assimilated or undertook to combat his views. Political ladies first, and statesmen afterwards, came to recognize the advantage of obtaining Hayward's good opinion. In this way the "old rèviewing hand" became an acknowledged link between Society, letters, and politics. As a professional man he was less successful; his promotion to be Q.C. in 1845 excited a storm of opposition, and, disgusted at not being elected a Bencher of his Inn in the usual course, Hayward virtually withdrew from legal practice. In February 1848 he became one of the chief leader-writers for the Peelite organ, the *Morning Chronicle*. The morbid activity of his memory, however, continued to make him many enemies. He alienated Disraeli by tracing a purple patch in his official eulogy of Wellington to a newspaper translation from Thiers's funeral panegyric on General St Cyr. His sharp tongue made an enemy of Roebuck, and he disgusted the friends of Mill by the stories he raked up for an obituary notice of the great economist (*The Times*, 10th May 1873). He broke with Henry Reeve in 1874 by a venomous review of the *Greville Memoirs*, in which Reeve was compared to the beggarly Scot deputed to let off the blunderbuss which Bolingbroke (Greville) had charged. His enemies prevented him from enjoying a well-selected *quasi*-sinecure, which both Palmerston and Aberdeen admitted to be his due. Warren attacked him (very unjustly, for Hayward was anything but a parasite) as Venom Tuft in *Ten Thousand a Year*; and Disraeli aimed at him partially in Ste Barbe (in *Endymion*), though the satire here was directed primarily against Thackeray. After his break with Reeve, Hayward devoted himself more exclusively to the *Quarterly*. His essays on Chesterfield and Selwyn were reprinted in 1854. Collective editions of his articles appeared in volume form in 1858, 1873, and 1874, and *Selected Essays* in two volumes, 1878. In his useful but far from flawless edition of the *Autobiography, Letters, and Literary Remains of Mrs* (*Thrale*) *Piozzi* (1861), he again appears as a supplementer and continuator of J. W. Croker. His *Eminent Statesmen and Writers* (1880) commemorates to a large extent personal friendships with such men as Dumas, Cavour, and Thiers, whom he knew intimately. As a counsellor of great ladies and of politicians, to whom he held forth with a sense of all-round responsibility surpassing that of a cabinet minister, Hayward retained his influence to the last years of his life. But he had little sympathy with modern ideas. He used to say that he had outlived every one that he could really look up to. He died, a bachelor, in his rooms at 8 St James's Street (a small museum of autograph portraits and reviewing trophies) on 2nd February 1884.

Two volumes of Hayward's *Correspondence* (edited by H. E. Carlisle) were published in 1886. In *Vanity Fair* (27th November 1875) he may be seen as he appeared in later life. (T. SE)

Hazara, a district of British India, in the Peshawar division of the Punjab, with an area of 2991 square miles. The population in 1881 was 407,075, and in 1891 was 516,288, giving an average density of 173 persons per square mile; in 1901 it was 710,668, showing an increase of 38 per cent. The land revenue and rates were Rs.2,90,495, the incidence of assessment being R.0–4–5 per acre; the cultivated area in 1896–97 was 419,540 acres, of which 55,674 were irrigated, mainly from private canals; the number of police was 487; the number of schools in 1896–97 was 458, with 8086 pupils, the proportion of boys at school to the male population of school-going age being 7·8 per cent.; the registered death-rate in 1897 was 23·30 per 1000. There are no railways, navigable rivers, or government canals in the district, and only 44 miles of metalled roads. There is one printing-press.

Hazaribagh, a town and district of British India, in the Chota Nagpur division of Bengal. Population (1881), 15,306; (1891), 16,672. There are a government high school, with 175 pupils in 1896–97, a central jail, with a daily average of 932 convicts, and a reformatory school, with 342 boys. It has ceased to be a military cantonment since the European penitentiary was abolished. Dublin University Mission maintains an English high school, with 139 boys. The DISTRICT comprises an area of 7021 square miles, with a population in 1881 of 1,104,742, and in 1891 of 1,164,315, giving an average density of 166 persons per square mile. Classified according to religion, Hindus numbered 960,187; Mahommedans, 114,773; aborigines, 87,866; Christians, 889, of whom 223 were Europeans; Jains, 600. In 1901 the population was 1,178,301, showing an increase of 1 per cent. The land revenue and rates were Rs.1,76,877; the number of police was 493; boys at school in 1896–97 numbered 14,252, being 16·7 per cent. of the male population of school-going age; the registered death-rate in 1897 was 48·12 per 1000, this great mortality being due to drought and high prices of grain. The district contains an important coalfield at Karharbari, which supplies the East Indian Railway. There are altogether six mines, employing 10,000 persons, with an out-turn of about 650,000 tons a year. There are also ten mica mines, which are gaining in importance, with an annual out-turn of 10,000 maunds, valued at Rs.1,74,000. Tea cultivation does not flourish. For 1897 four gardens

furnished returns, with 611 acres under tea, producing 36,200 lb. The only railway is the branch of the East Indian to the coalfield at Giridhi, where there is a technical school maintained by the railway company; but the district is traversed by the Grand Trunk Road.

Hazleton, a city of Luzerne county, Pennsylvania, U.S.A., in 40° 57′ N. and 75° 58′ W., on Hazle Creek and on the Lehigh Valley Railway. It is in a level valley, and its plan is regular. It is situated within the anthracite coal district, and its industries are largely connected with coal-mining. Population (1880), 6935; (1890), 11,872; (1900), 14,230, of whom 2732 were foreign-born.

Heanor, a parish and village in the Ilkeston division of Derbyshire, England, 10 miles north-west of Nottingham, with a station, opened in 1890, on the Midland Railway. The church is an ancient edifice, in great part rebuilt, and there are several other places of worship. A technical school is installed in Heanor Hall. Large hosiery works employ over 1000 persons, and collieries are worked in the parish. Population of the urban district, which includes Codnor-cum-Loscoe (1901), 16,249.

Heat. See separate articles CALORIMETRY, CONDUCTION, &c.

Hebburn, a town and railway station in the Jarrow parliamentary division of county Durham, England, on the Tyne, 4 miles east-north-east of Gateshead. The churches are—three Established, Roman Catholic, Presbyterian, and Methodist (various). There are also a mechanics' institute, a drill-hall, and a theatre. It has extensive shipbuilding and engineering works, rope and sail factories, and chemical, colour, and cement works. Area of urban district, 1180 acres. Population (1881), 11,802; (1901), 20,901.

Hebden Bridge, a town and railway station in the Sowerby parliamentary division of Yorkshire, England, on the Calder and Hebden, 7 miles west by north of Halifax. There is a parish church, and two Wesleyan and three Baptist chapels. The town has cotton factories, dye-works, foundries, and manufactories of shuttles. There is fine scenery in the neighbourhood. Area of urban district (a civil parish), 478 acres; population (1881), 5007; (1901), 7536.

Hebrides, The, or WESTERN ISLES, a large group of islands off the west coast of Scotland, between 55° 35′ and 58° 30′ N. and 5° 40′ and 8° 40′ W. They consist of two chief groups, the Outer Hebrides—comprising, amongst others, Lewis, Harris, North and South Uist, Benbecula, Barra—and the Inner Hebrides, which are more scattered, and the principal of which are Skye, Rum, Eigg, Canna, Coll, Tiree, Mull, Iona, Colonsay, Jura, and Islay. The former group is attached to the counties of Ross and Inverness, the latter to the shires of Inverness and Argyll. Lewis and Harris, Skye, and North and South Uist are noticed under separate headings.

Hebron, now el-Khalîl, some 20 miles S. by S.W. of Jerusalem, in 31° 32′ N. and 35° 6′ E., with an altitude of 3040 feet. There are a British medical mission, a German Protestant mission with church and schools, and, near Abraham's Oak, a Russian mission. Since 1880 several notices of the Harám, within which are the tombs of the Patriarchs, have appeared.

Hefele, Karl Josef von (1809–1893), German theologian, was born in Würtemberg on 15th March 1809. In 1839, after his ordination to the priesthood, he became professor of the Catholic Faculty of Theology at Tübingen. In 1842 he became a member of the National Assembly of Würtemberg. In 1869 he was made bishop of Rottenburg. His literary activity, which had been considerable, was in no way diminished by his elevation to the episcopate. Among his numerous theological works may be mentioned his well-known edition of the *Apostolic Fathers*, issued in 1839; his *Life of Cardinal Ximenes*, published in 1844; and his still more celebrated *History of the Councils of the Church*, in seven volumes, which appeared between 1865 and 1874. His theological opinions inclined towards the more liberal school in the Roman Catholic Church, but he nevertheless received considerable signs of favour from its authorities. He was made one of the special advisers of the Pope. When the Vatican Council of 1870 was about to assemble he published at Naples his *Causa Honorii Papae*, which aimed at demonstrating the moral and historical impossibility of Papal infallibility. About the same time he brought out a work in German on the same subject. He took rather a prominent part in the discussions at the council, associating himself with Dupanloup and Darboy in his opposition to the doctrine of Infallibility, and supporting their arguments from his large stores of knowledge of ecclesiastical history. In the preliminary discussions he voted against the promulgation of the dogma. He was absent from the important sitting on 18th June 1870, and did not send in his submission to the decrees until 1871. But in 1872 he took part in the congress summoned by the Ultramontanes at Fulda, and by his judicious use of minimizing tactics he kept his diocese free from any participation in the Old Catholic schism. The last four volumes of the second edition of his *History of the Councils* have been described as skilfully adapted to the new situation created by the Vatican decrees. During the later years of his life he undertook no further literary efforts on behalf of his Church, but retired into comparative privacy. He died on 6th June 1893. (J. J. L*.)

Heidelberg, a town of Germany, grand-duchy of Baden, on the river Neckar, 13 miles by rail south-east of Mannheim. The town has continued to grow towards the south-west, a new villa quarter having been built there, partly on the slopes of the Geisberg, partly in the plain at its foot. At the same end of the town the "new" bridge (1877) connects the Bismarck Square or Gardens with Neuenheim on the opposite bank of the Neckar, but now really an integral part of Heidelberg. A little lower down, and on the Heidelberg side of the river, are the botanical gardens of the university. A wire-rope railway runs from the Corn Market up to the level of the castle, and is continued thence to the Molkenkur (348 feet above the castle), a favourite point of view for seeing the beauties of the neighbourhood. In 1894 a double observatory was founded on the Geisberg, above the castle hill, and on the "great terrace" of the castle a monument to Viktor von Scheffel, unveiled in 1891, testifies the town's gratitude to the poet's praise of her. The university was frequented by 1553 students in 1900, and had 149 professors. Its library numbers 400,000 volumes and 4500 MSS. The university buildings were restored in part in 1886. Its institutions embrace a children's hospital, zoological and mineralogical museums, and a botanical garden, all connected with the university; also a technical school and Dr Schweninger's sanatorium. Population (1885), 29,364; (1900), 40,119.

Heidenheim, a town of Würtemberg, in Germany, 31 miles by rail north by east of Ulm. It is the seat of cotton and woollen, tobacco, machinery, and chemical factories, bleaching-grounds, dyeworks, and breweries, and corn and cattle markets. It is overlooked by the ruins of the castle of Hellenstein. Population (1885), 6709; (1901), 10,439.

Heilbronn, a town of Würtemberg, Germany, 33 miles by rail north of Stuttgart, and on the river Neckar. The church of St Kilian's was thoroughly restored in 1886–95. The town possesses a historical museum, a fine synagogue, and monuments to the emperors William I. and Frederick III. and to Schiller, as well as to Robert Mayer (1814–78), a native of the town, whose name is associated with the discovery of the mechanical theory of heat. Population (1885), 27,758; (1901), 37,883.

Helder, or Den Helder, a town in the province of North Holland, Netherlands, 40 miles north by west of Amsterdam, on the Marsdiep, the old sea road to Amsterdam. Before the construction of the North Sea Canal its harbour, the Nieuwe Diep, and the North Holland Canal served as an outer port to Amsterdam. It is now a fortified maritime station of the first class, with numerous batteries and forts, an arsenal, docks, and a state wharf. The garrison and marine establishments sustain the industries of the town, which has a zoological station. Population (1900), 25,159.

Helena, capital of Phillips county, Arkansas, U.S.A., on the west bank of the Mississippi, at an altitude of 193 feet. It is on the Arkansas Midland, the St Louis, Iron Mountain and Southern, and the Yazoo and Mississippi Valley railways. Situated in the alluvial region of the lower Mississippi, the richest cotton-producing region on earth, it is an important compressing and shipping point for cotton. It contains also cotton-seed oil and lumber mills. Population (1880), 3652; (1900), 5550, of whom 265 were foreign-born and 3400 were negroes.

Helena, capital of Lewis and Clark county and of the state, Montana, U.S.A., in 46° 37′ N. and 112° 03′ W., at the eastern base of the Rocky Mountains, at an altitude of 4009 feet. It was founded as a mining camp in 1864, in Little Prickly Pear Gulch, but has now spread down the narrow gulch and over the broad valley below. Most of its site is level, but its plan is irregular. It is entered by the Northern Pacific and the Great Northern railways, with several branches connecting it with neighbouring mining districts. It is said to be the wealthiest city in the United States in proportion to its population, and it is the financial centre of Montana, as Butte is the mining centre. It is the seat of the Montana Wesleyan University, a Methodist Episcopal institution, founded in 1890, which in 1899 had 15 instructors and 77 students. Population (1880), 3624; (1890), 13,834; (1900), 10,770, of whom 2793 were foreign-born and 228 were negroes.

Helensburgh, a burgh of barony and police burgh of Dumbartonshire, Scotland, on the north shore of the Firth of Clyde, opposite Greenock, 23 miles west-north-west of Glasgow by rail. Most of the inhabitants are Glasgow business men. Numerous villas have sprung up; Roman Catholic, Congregational, and Baptist chapels, and Victoria Halls have been erected. There are also a fever hospital and a monument to Henry Bell, the pioneer of steam navigation, who died here. Population (1881), 7693; (1901), 8554.

Heller, Stephen (1815–1888), Austrian pianist and composer, was born at Pesth, 15th May 1815. (Fétis's dictionary says 1814, but this is almost certainly wrong.) He was at first intended for a lawyer, but at nine years of age performed so successfully at a concert that he was sent to Vienna to study under Czerny. Halm was his principal master, and from the age of twelve he gave concerts in Vienna, and made a tour through Hungary, Poland, and Germany. At Augsburg he had the good fortune to fall ill and to be befriended by a wealthy family, who practically adopted him and gave him the opportunity to complete his musical education. In 1838 he went to Paris, and soon became intimate with Liszt, Chopin, Berlioz, and the set of romantics, among whom was Hallé, throughout his life an indefatigable performer of Heller's music. In 1849 he came to England and played a few times, and in 1862 he appeared with Hallé at the Crystal Palace. He outlived the great reputation he had enjoyed among cultivated amateurs for so many years, and was almost forgotten when he died at Paris on 14th January 1888. His pianoforte pieces, almost all of them published in sets and provided with fancy names, do not perhaps show very startling originality, but their grace and refinement could not but make them popular with players and listeners of all classes. He was by far the best of the composers who wrote nothing but what is called "drawing-room" music. (J. A. F. M.)

Heligoland, in German *Helgoland*, one of the Frisian Islands, belonging to Prussia, to which it was ceded by Great Britain in 1890, situated in the North Sea, 28 miles north-west from the mouth of the Elbe, in 54° 10′ N. and 7° 53′ E. Since its cession by Great Britain (see Germany: *History*) the island has been strongly fortified, the old English batteries having given place to armoured turrets mounting guns of the heaviest calibre. It has thus become an important strategical base for the German navy. Inside the Düneninsel the largest ships can ride safely at anchor and take in coal and other supplies. In 1892 a biological institute, with a marine museum and aquarium (1900) attached, was opened. It now claims to be the most fashionable watering-place in Germany, and during the season—June to October—it is largely resorted to by visitors from Hamburg and other German towns for sea-bathing. In 1899, 854 vessels of 161,723 tons cleared the island. Since 1891 it has been attached to the province of Schleswig-Holstein. Population (1900), 2307.

Helmholtz, Hermann Ludwig Ferdinand von (1821–1894), German philosopher and man of science, was born on 31st August 1821 at Potsdam, near Berlin. His father, Ferdinand, was a teacher of philology and philosophy in the Gymnasium, while his mother was a Hanoverian lady, a lineal descendant of the great Quaker William Penn. Delicate in early life, Helmholtz became by habit a student, and his father at the same time directed his thoughts to natural phenomena. He soon showed mathematical powers, but these were not fostered by the careful training mathematicians usually receive, and it may be said that in after years his attention was directed to the higher mathematics mainly by force of circumstances. As his parents were poor, and could not afford to allow him to follow a purely scientific career, he became a surgeon of the Prussian army. In 1842 he wrote a thesis in which he announced the discovery of nerve-cells in ganglia. This was his first work, and from 1842 to 1894, the year of his death, scarcely a year passed without several important, and in some cases epoch-making, papers on scientific subjects coming from his pen. He lived in Berlin from 1842 to 1849, when he became professor of physiology in Königsberg. There he remained from 1849 to 1855, when he removed to the chair of physiology in Bonn. In 1858 he became professor of

physiology in Heidelberg, and in 1871 he was called to occupy the chair of physics in Berlin. To this professorship was added in 1887 the post of director of the physio-technical institute at Charlottenburg, near Berlin, and he held the two positions together until his death on the 8th of September 1894.

His investigations occupied almost the whole field of science, including physiology, physiological optics, physiological acoustics, chemistry, mathematics, electricity and magnetism, meteorology, and theoretical mechanics. At an early age he contributed to our knowledge of the causes of putrefaction and fermentation. In physiological science he investigated quantitatively the phenomena of animal heat, and he was one of the earliest in the field of animal electricity. He studied the nature of muscular contraction, causing a muscle to record its movements on a smoked glass plate, and he worked out the problem of the velocity of the nervous impulse both in the motor nerves of the frog and in the sensory nerves of man. In 1847 Helmholtz read to the Physical Society of Berlin a famous paper, *Ueber die Erhaltung der Kraft* (on the conservation of force), which became one of the epoch-making papers of the century; indeed, along with Mayer, Joule, and Thomson (Lord Kelvin), he may be regarded as one of the founders of the now universally received law of the Conservation of Energy. The year 1851, while he was lecturing on physiology at Königsberg, saw the brilliant invention of the ophthalmoscope, an instrument which has been of inestimable value to medicine. It arose from an attempt to demonstrate to his class the nature of the glow of reflected light sometimes seen in the eyes of animals such as the cat. When the great ophthalmologist, von Graefe, first saw the fundus of the living human eye, with its optic disc and blood-vessels, his face flushed with excitement, and he cried, "Helmholtz has unfolded to us a new world!" Helmholtz's contributions to physiological optics are of great importance. He investigated the optical constants of the eye, measured by his invention, the ophthalmometer, the radii of curvature of the crystalline lens for near and far vision, explained the mechanism of accommodation by which the eye can focus within certain limits, discussed the phenomena of colour vision, and gave a luminous account of the movements of the eyeballs so as to secure single vision with two eyes. In particular he revived and gave new force to the theory of colour-vision associated with the name of Thomas Young, showing the three primary colours to be red, green, and violet, and he applied the theory to the explanation of colour-blindness. His great work on *Physiological Optics* (1856–66) is by far the most important book that has appeared on the physiology and physics of vision. Equally distinguished were his labours in physiological acoustics. He explained accurately the mechanism of the bones of the ear, and he discussed the physiological action of the cochlea on the principles of sympathetic vibration. Perhaps his greatest contribution, however, was his attempt to account for our perception of quality of tone. He showed, both by analysis and by synthesis, that quality depends on the order, number, and intensity of the over-tones or harmonics that may, and usually do, enter into the structure of a musical tone. He also developed the theory of differential and of summational tones. His work on *Sensations of Tone* (1862) may well be termed the *principia* of physiological acoustics. He may also be said to be the founder of the fixed-pitch theory of vowel tones, according to which it is asserted that the pitch of a vowel depends on the resonance of the mouth, according to the form of the cavity while singing it, and this independently of the pitch of the note on which the vowel is sung. For the later years of his life his labours may be summed up under the following heads: (1) On the conservation of energy; (2) on hydrodynamics; (3) on electro-dynamics and theories of electricity; (4) on meteorological physics; (5) on optics; and (6) on the abstract principles of dynamics. In all these fields of labour he made important contributions to science, and showed himself to be equally great as a mathematician and a physicist. He studied the phenomena of electrical oscillations from 1869 to 1871, and in the latter year he announced that the velocity of the propagation of electromagnetic induction was about 314,000 metres per second. Faraday had shown that the passage of electrical action involved time, and he also asserted that electrical phenomena are brought about by changes in intervening non-conductors or dielectric substances. This led Clerk Maxwell to frame his theory of electro-dynamics, in which electrical impulses were assumed to be transmitted through the ether by waves. Fitzgerald was the first to attempt to measure the length of electric waves; Helmholtz put the problem into the hands of his favourite pupil, Heinrich Hertz, and the latter finally gave an experimental demonstration of electromagnetic waves, the "Hertzian waves," on which the invention of wireless telegraphy depends, and the velocity of which is the same as that of light. The last investigations of Helmholtz related to problems in theoretical mechanics, more especially as to the relations of matter to the ether, and as to the distribution of energy in mechanical systems. In particular he explained the principle of least action, first advanced by Maupertuis, and developed by Hamilton, of quaternion fame. Helmholtz also wrote on philosophical and æsthetic problems. His position was that of an empiricist, denying the doctrine of innate ideas and holding that all knowledge is founded on experience, hereditarily transmitted or acquired.

The life of Helmholtz was uneventful in the usual sense. He was twice married, first, in 1849, to Olga von Velten (by whom he had two children, a son and daughter), and secondly, in 1861, to Anna von Mohl, of a Würtemberg family of high social position. Two children were born of this marriage, a son, Robert, who died in 1889, after showing in experimental physics indications of his father's genius, and a daughter, who married a son of Werner von Siemens. Helmholtz was a man of simple but refined tastes, of noble carriage, and somewhat austere manner. His life from first to last was one of devotion to science, and he must be accounted, on intellectual grounds, one of the foremost men of the 19th century. (J. G. M.)

Helmond, town of the province of North Brabant, Netherlands, on the canal between Bois-le-Duc and Maastricht (*Zuid-Willems vaart*), and on the railway from Boxtel to Venlo, 21 miles south-east of Bois-le-Duc. It is one of the industrial centres of the province, and has twenty-two factories, employing 3000 workpeople in weaving, dyeing, and printing cotton, engine works, a margarine manufactory, &c. There is an art school. Population with suburbs (1900), 11,436.

Helmstedt, a town of Germany, duchy of Brunswick, 30 miles west by north of Magdeburg by rail. The Walpurgis church was restored in 1893–94. There is a new classical school (1880–82). The agricultural school is quartered in the Marienberg nunnery (1176). Coal is mined in the vicinity. Population (1885), 9794; (1900), 14,259.

Helsingborg, a growing seaport town of Sweden, on the east side of the Sound, opposite to Elsinore (Helsingör) in Denmark, 56 miles by rail west-north-west of Malmö. The harbour, which is of artificial construction, was deepened in 1888–89, and subsequently enlarged to

2200 feet by 450 feet, with 24 feet depth. The export of agricultural produce has steadily declined since 1888, but other exports have increased. The chief exports are timber (nearly 2 million cubic feet), butter, and iron. In 1900, 4620 vessels of 756,300 tons cleared, as compared with 3749 vessels of 228,600 tons in 1886. The merchant fleet numbers 110 vessels of nearly 51,000 tons. There are several handsome new buildings, chief amongst them being the town hall (1894–96) and the church of Gustavus Adolphus (1897). Population (1880), 11,550; (1900), 24,670.

Helsingfors (Finnish, *Helsinki*), a seaport and the capital of Finland and of the government of Nyland, centre of the administrative, scientific, and industrial life of Finland. The fine harbour is divided into two parts by a promontory, and is protected at its entrance by a group of small islands, on one of which stands the fortress of Sveaborg. A third harbour is situated on the west side of the promontory, and all three have granite quays. Near the southern harbour is the market square, upon which stands the imperial palace. The finest street, the Esplanade, leads from it, and has a monument to Runeberg, two theatres (Swedish and Finnish), an athenæum (drawing and professional school), and other important buildings. There are also two excellent parks, many museums of natural sciences, antiquities, and art, several large libraries, and a "people's palace," founded by Miss Ally Trugg. Some of its scientific societies have a wide repute, such as the academy of sciences, the geographical, historical, Finno-Ugrian, biblical, medical, law, arts, and forestry societies, as also societies for spreading popular education, of arts and crafts, for the study of the flora and fauna, and so on. Five daily papers and a great number of other periodicals are published, in addition to admirable works of the geological survey, the land survey, the administration of roads and water communication, forestry, and other departments of government. The population, which was 32,113 in 1870, has rapidly grown since the construction of railways, and in 1899 was, with Sveaborg, 73,820. Nearly 55 per cent. speak Swedish and 36 Finnish, the remainder being Russians and Germans. The aggregate yearly production of all manufactories is about £1,000,000. The trade is important, Helsingfors being the chief port of Finland for imports (customs duties, £248,020), the total returns of foreign and coasting trade reaching about £2,000,000. It is visited every year by 760 vessels, 253,000 tons. It is connected by rail with St Petersburg (263 miles, *viâ* the Rihimäki junction) and Hangö (138 miles, at the entrance into the Gulf of Finland), as also with all the chief towns of Finland as far north as Uleåborg, Kuopio, and Ioensuu.

Helvoetsluys (Dutch, *Hellevoetsluis*), town, Netherlands, province of South Holland, 17 miles W.S.W. of Rotterdam. Formerly an outer port to Rotterdam, it is, since the construction of the new waterway from Rotterdam to the sea, only a fortified marine station and port. Population (1900), 4293.

Hemichorda.—This zoological term was introduced by Bateson in 1884, without special definition, as equivalent to Enteropneusta, which then included the single genus Balanoglossus. It has since been extended so as to embrace some other forms, the anatomy of which was at that time imperfectly known. The special attention which has of late years been devoted to these animals is due to the fact that they are generally considered to lie near the base of the Vertebrata, and may eventually throw some light on the origin of that great stem from invertebrate ancestors. The relations of the Hemichorda and allied groups may be represented by the following table:—

I. HEMICHORDA. Bateson.
  1. *Vermiformia*, Lankester . . Phoronis.
  2. *Pterobranchia*, Lankester . . {Cephalodiscus. Rhabdopleura.
  3. *Enteropneusta*, Gegenbaur . . {Balanoglossus and others.
II. PROTOCHORDA, Balfour.
  1. *Urochorda*, Lankester . . . {Ascidians or Tunicata.
  2. *Cephalochorda*, Lankester . . {Amphioxus and others.
III. VERTEBRATA=Craniata, Euchorda, Holochorda, &c.

The external features of *Phoronis* and of its larva were described and figured in *Ency. Brit.*, vol. xix. pp. 433, 434. Internally the body cavity is divided by a septum into an anterior lophophoral ("collar") cavity and a posterior ("trunk") cavity. The alimentary canal is U-shaped, bent dorsally, and supported in the trunk

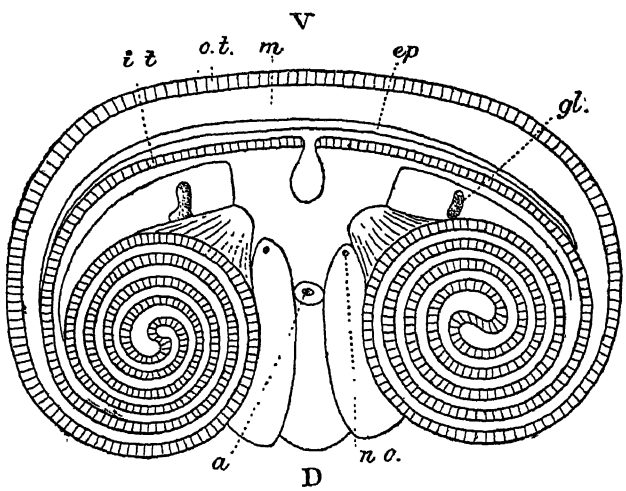

FIG. 1.—Anterior end of *Phoronis australis*, the tentacles cut off short at their origins. *a*, anus; D, dorsal surface; *ep*, epistome; *gl*, supposed glandular pit; *i.t.*, bases of inner series of tentacles; *m*, mouth; *n.o.*, nephridial opening; *o.t.*, bases of outer series of tentacles; V, ventral surface. (*After Benham.*)

cavity by mesenteries; the chambers between these latter are not completely separated from one another. The blood system is complex. There is a pair of typical nephridia, each with two funnels, which open on opposite sides of a mesentery; they appear to serve also as genital ducts. The nervous system lies immediately below the ectoderm; there is a nerve band along the spiral lophophore, with nerves to the tentacles and elsewhere; a slight concentration of nerve-cells between mouth and anus may represent an indefinite central ganglion (Figs. 1, 2). Two ectodermal pits, containing specialized cells, lying dorsally to the inner series of tentacles, have been variously interpreted as glands and as sense-organs. Segmentation is holoblastic and sub-equal; the blastula undergoes an embolic gastrulation. According to Masterman, the blastopore persists as the mouth. The larva is known as *Actinotrocha*. Its body cavity is divided into three sections: a protocœle (head or proboscis cavity), which is formed as a two-horned archenteric diverticulum, similar to those of *Amphioxus* and of the directly developing *Balanoglossus*; a mesocœle (collar cavity), arising as a pair of at first solid masses of cells, probably by proliferation of endoderm cells outwardly; and a metacœle (trunk cavity), formed as a pair of endodermal outgrowths, which may possibly have been originally archenteric diverticula. The anatomy of the larva is represented in Figs. 3, 4, and will be further discussed later. In metamorphosis

the præ-oral lobe (proboscis or hood) is apparently absorbed or swallowed, carrying with it the central nervous system; the adult thus has no protocœle. According to Ikeda, the mesocœle of the larva becomes a vascular space; that of the adult is a new formation.

The external characters of *Cephalodiscus* and *Rhabdopleura*, with figures, will be found in *Ency. Brit.*, vol.

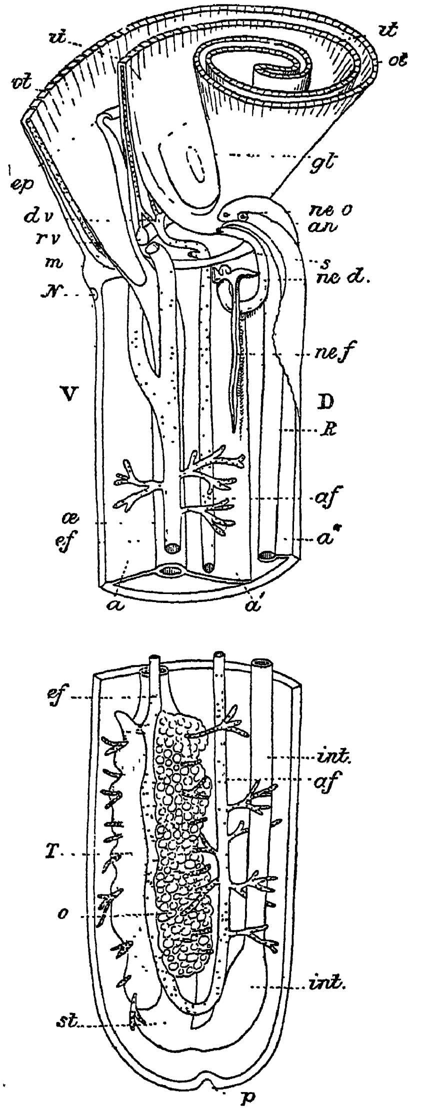

FIG 2.—Diagram of the anterior and posterior ends of *Phoronis*, the left half of the body-wall cut away: in the upper half, the left lateral mesentery cut away, but the left nephridium untouched; in the lower half all mesenteries omitted. *a*, œsophageal mesentery; *a'*, right lateral mesentery; *a''*, rectal mesentery; *af*, afferent vessel; *an*, anus; D, dorsal side; *d.v.*, right vessel supplying tentacles; *ef*, efferent vessel; *ep*, epistome; *gl*, "glandular" pit; *int.*, intestine; *i.t.*, bases of inner whorl of tentacles; *m*, mouth; *N*, nerve-band; *ne. d.*, nephridial duct; *ne. f.*, large nephridial funnel, opening into rectal chamber; the smaller funnel, which opens into the œsophageal chamber, is to the left of the top of the larger; *ne. o.*, nephridial opening to the exterior; *o*, ovary; *œ*, œsophagus; *o.t.*, bases of outer whorl of tentacles; *p*, posterior pit; *R*, rectum; *r.v.*, right vessel receiving blood from tentacles; *s*, septum between mesocœle and metacœle; *st*, stomach; *T*, testis; V, ventral side. (*Modified from drawings by Benham.*)

xix. pp. 434–436. In addition to, or in correction of, the information there given, the following points should be noted:—The præ-oral lobe or buccal shield of *Cephalodiscus* corresponds, not to the little epistome of *Phoronis*, but to the præ-oral lobe of *Actinotrocha*. Protocœle, mesocœle, and metacœle are well marked. The protocœle opens by two pores to the exterior, through the front part of that concentration of nerve matter which appears to represent a cerebral ganglion or brain; the mesocœle, which is continued into the lophophore and tentacles, opens also by two "collar pores." The alimentary canal is U-shaped, flexed dorsally; it has a pair of gill slits, and gives off an anterior cæcum (notochord, stomochord). A pair of ovaries, formerly regarded as eyes, lie in the metacœle, and open by oviducts to the exterior; the male organs have not been seen. A stalk or stolon, on the ventral side of the body posteriorly, contains a portion of the metacœle divided into two by a mesentery, a ventral nerve, and spaces interpreted by Masterman as blood sinus; from this pedicle are developed the buds, of which the whole alimentary canal is formed by an invagination of ectoderm at the site of the mouth. The buds become detached from the stolon, and free in the cœnœcium (Figs. 5, 6).

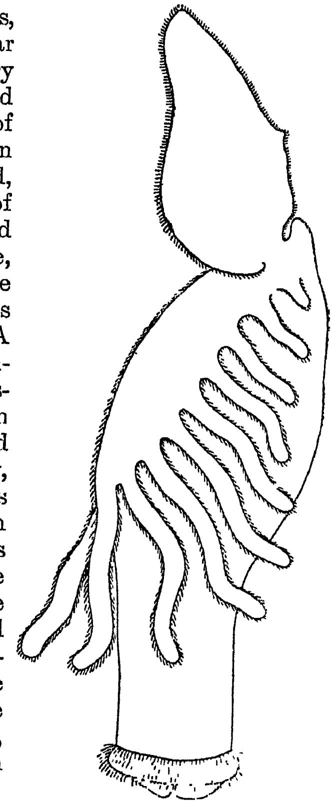

FIG. 3.—Lateral view of a late *Actinotrocha* larva of *Phoronis*. (*After Masterman.*)

Rhabdopleura has been shown to possess protocœle, mesocœle with collar pores (the "ciliated patches" of the earlier article), and metacœle; a stomochord, and nerve ganglion, all as in *Cephalodiscus*. Proboscis pore and gill slits have not been detected, possibly owing only to the minuteness of the animal. There is a stolon of similar structure and position to that of *Cephalodiscus*, but each individual budded from this remains permanently attached at the end of his branch of the adherent ramifying stolon, which unites all the individuals into a true colony. Nothing is known of the embryology of *Rhabdopleura*, and practically nothing of that of *Cephalodiscus*.

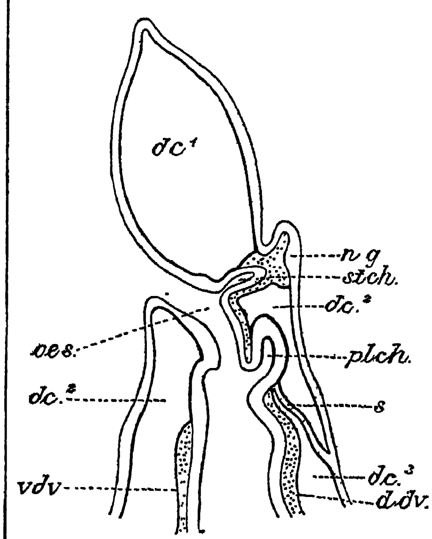

FIG. 4.—Anterior part of a dorso-ventral section of *Actinotrocha* (not exactly median): *dc*¹, protocœle; *dc*², mesocœle; *dc*³, metacœle; *dbv*, dorsal blood-vessel; *n.g.*, nerve ganglion; *œs.*, œsophagus; *plch*, pleurochord of one side; *s*, septum between mesocœle and metacœle; *stch*, stomochord; *vbv*, ventral blood-vessel. (*Modified from a drawing by Masterman.*)

The *Enteropneusta* are described in a separate article, BALANOGLOSSUS.

The reader can only estimate the homological value of the various internal structures of forms, at first sight so

distinct from one another, after a careful study of the memoirs cited below; the most that can be done here is to point out the more salient features which have led to the association of those animals as Hemichorda.

The Notochord.—This structure, which occurs in the embryos of all Vertebrata, and persists in many of them throughout life, has always been recognized as one of their chief morphological characters. It is not disputed that this is homologous with the notochord of *Amphioxus*, and only a few authorities refuse to admit some relationship between the latter and the "notochord" of *Enteropneusta*, for which Willey's term "stomochord" will here be used. The stomochord is a forward dorsal diverticulum of the gut in the collar region, which pushes before it the wall of the præ-oral body cavity or protocœle. According to Willey, its completest development is represented in

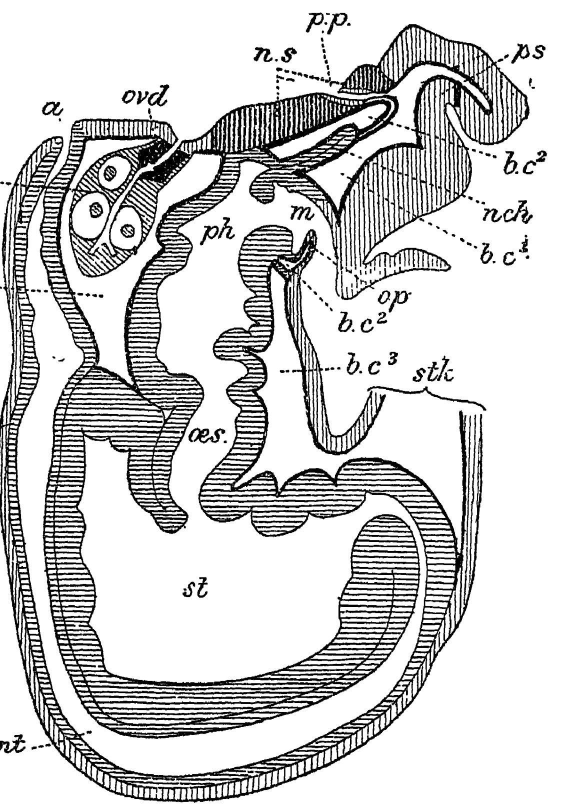

FIG. 5.—Dorso-ventral section of an adult *Cephalodiscus* (not exactly median): *a*, anus; *bc*1, protocœle; *bc*2, mesocœle; *bc*3, metacœle; *int.*, intestine; *m*, mouth; *nch*, stomochord; *n.s.*, nervous system; *œs.*, œsophagus; *op*, operculum; *ov*, ovary; *ovd*, oviduct; *vh*, pharynx; *p.p.*, proboscis pore; *p.s.*, proboscis stalk; *st*, stomach; *stk*, cut origin of stolon or pedicle. (*After Harmer.*)

Fig. 1; the cells of which it is composed frequently exhibit that vacuolation which is generally associated with a stiffening function, and is particularly well developed in Vertebrate notochords. In *Cephalodiscus* and *Rhabdopleura* there exists a simpler diverticulum or stomochord, with the same general relations, but not exhibiting vacuolation. As regards *Actinotrocha*, we suffer from a multiplicity of so-called "notochords." Masterman describes in *Actinotrocha* and *Cephalodiscus* a pair of "pleurochords," lateral evaginations of the gut in the collar region, the cells of which are vacuolated; these lie farther back than the Enteropneustan stomochord, and do not project into the protocœle. Roule in the *Actinotrocha* of another species of *Phoronis*, and Ikeda in Japanese species, describe not two, but a single diverticulum of vacuolated cells in the collar; this projects, however, not dorsally towards the protocœle, but ventrally, not above but below the œsophagus. On the other hand, Masterman, and (more recently) Menon in Indian species, describe a median dorsal non-vacuolated diverticulum; this, although formed just outside what he describes as the mouth, shifts inwards, and comes to have the topographical relations of a stomochord. He formerly regarded this and the stomochord of *Cephalodiscus* as homologous with the subneural gland of *Urochorda*, refusing to recognize it as of notochordal significance on the grounds of its structure, of its relations to other organs, and of his preference for regarding the pleurochords as the paired homologues of the Enteropneust stomochord. As regards the question of histological structure, it is not wise to lay too much stress on this evidence; the vacuolated cells of *Cephalodiscus* and *Actinotrocha* are not particularly chordoid-looking, and there is no evidence of their being stiffer than surrounding tissues; there appear to be gland cells among them. Further, Spengel, Hill, and Willey have shown that "pygochordal" vacuolated tissue occurs on the ventral side of the caudal gut in various *Enteropneusta*; again, chordoid tissue of a stiffening nature is widely distributed in the animal kingdom, from the tentacles of Hydromedusæ upwards. The general topographical relations of the organ are those of the stomochord of *Enteropneusta*, although in details of this as of other portions of their anatomy the three smaller members differ from *Enteropneusta*. On the whole, there seems little reason at present to deny to this median stomochord in *Actinotrocha*, *Rhabdopleura*, and *Cephalodiscus* a homology with at any rate some part of the stomochord of *Enteropneusta*. This would agree with the homologies suggested by Willey, that the pleurochords are homologous with the lateral pouches, and Roule's ventral diverticulum with the ventral cæcum, of such an Enteropneust stomochord as is represented in Fig. 7.

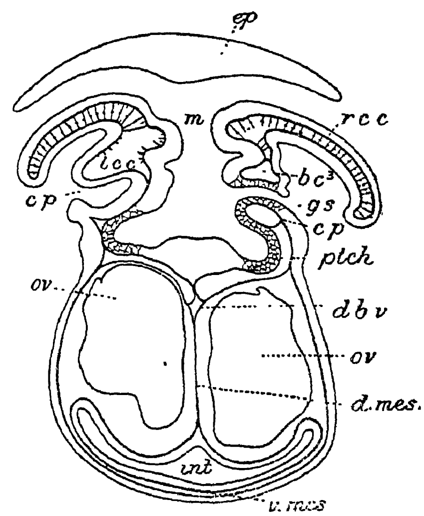

FIG. 6.—Nearly transverse section of *Cephalodiscus*: *bc*3, metacœle; *c.p*, collar pore; *dbv*, dorsal blood-vessel; *d. mes.*, dorsal mesentery; *ep.* epistome; *g s.*, gill slit; *int*, intestine; *l.c.c.*, left mesocœle; *m*, mouth; *ov.*, ovary; *plch*, pleurochord; *r.c c*, right mesocœle; *v. mes.*, ventral mesentery. The distribution of the "chordoid" tissues on gill slits and pleurochords is shown by reticulations. (*Modified from a drawing by Masterman.*)

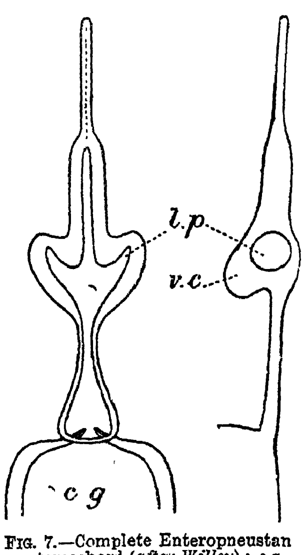

FIG. 7.—Complete Enteropneustan stomochord (*after Willey*): *c.g.*, collar gut; *l.p.*, lateral pouch; *v.c.*, ventral cæcum.

The Cœlom and its Openings.—In all the Hemichorda the cœlom exhibits three well-defined regions separated from one another by septa: (1) An impaired præ-oral protocœle (head or proboscis cavity), which is present in

Actinotrocha, but lost in adult *Phoronis*, and persists in the other three; (2) a mesocœle (collar or lophophoral cavity), first paired, then single, in *Actinotrocha;* paired in the remainder, and continued into the lophophore and tentacles when they occur; (3) a paired metacœle or trunk cavity. It is interesting to note that these three are present in the development of *Amphioxus* (MacBride, *Quart. Journ. Micr. Science*, xl. 589). The protocœle and mesocœle communicate with the exterior by pores or canals, presumably for excretory functions; the protocœle by two pores in *Actinotrocha* and *Cephalodiscus*, by two or one in *Enteropneusta*, but none have been observed in *Rhabdopleura;* the mesocœle opens by a pair of pores in all cases.

Gill-slits.—While the *Enteropneusta* have numerous gill-slits, *Cephalodiscus* has but a single pair, and none have been detected in *Rhabdopleura* or *Actinotrocha;* it is less remarkable that two such small animals as the latter should lack them, than that *Cephalodiscus* should possess them. The pleurochords of *Cephalodiscus* and *Actinotrocha*, as Willey suggests, are possibly vestiges of a lost pair of gill-slits; their size, shape, and position, and the presence of vacuolated tissue in the walls of both (Fig. 6), render this homology probable.

These points are enough to show that the marked morphological similarities justify the inclusion of these three forms among the Hemichorda. But how they stand phylogenetically to each other and to *Euchorda*, whether they or any of them represent in any sense an ancestral phase, a blind side-path, or a degradation of structure, there is at present no adequate evidence to show.

The three forms treated here are sessile, and in this point bear to the *Enteropneusta* a relation analogous to that between many Ascidians and the Cephalochorda, an analogy the more striking if that interpretation be accepted which assigns to the Ascidians a single pair of gill-slits, greatly enlarged and subdivided.

Mention should be made here of a curious resemblance in many anatomical points between *Phoronis* and the Sipunculoidea (*Gephyrea inermia*), but our knowledge of the development of the latter group does not at present tend to show any intimate relationship between the two.

Hems, or HUMS, ancient *Emessa*, a town of Syria, on the right bank of the Orontes. After its capitulation it became the capital of a *jund*, or military district, which under the Omeiyad Caliphs extended from Palmyra to the sea. Under the Arabs it was one of the largest cities in Syria, with walls and a strong citadel, which stood on a hill. Its men were noted for their courage in war, and its women for their beauty. The climate was extolled for its excellence, and the land for its fertility. A succession of gardens bordered the Orontes, and the vineyards were remarkable for their abundant yield of grapes. When it capitulated the great church of St John was divided between the Christians and Moslems, an arrangement which apparently lasted until the arrival of the Turks. Its decay probably dates from the invasion of the Mongols (1260), who fought two important battles with the Egyptians (1281 and 1299) in its vicinity. The construction of a carriage road to Tripolis has led to a partial revival of prosperity and to an export of cereals and fruit. The population numbers 30,000 (Moslems 20,000, Christians 10,000). About 7 miles above Hems is the mediæval Lake Kedes, in the vicinity of which was the Hittite city Kedesh.

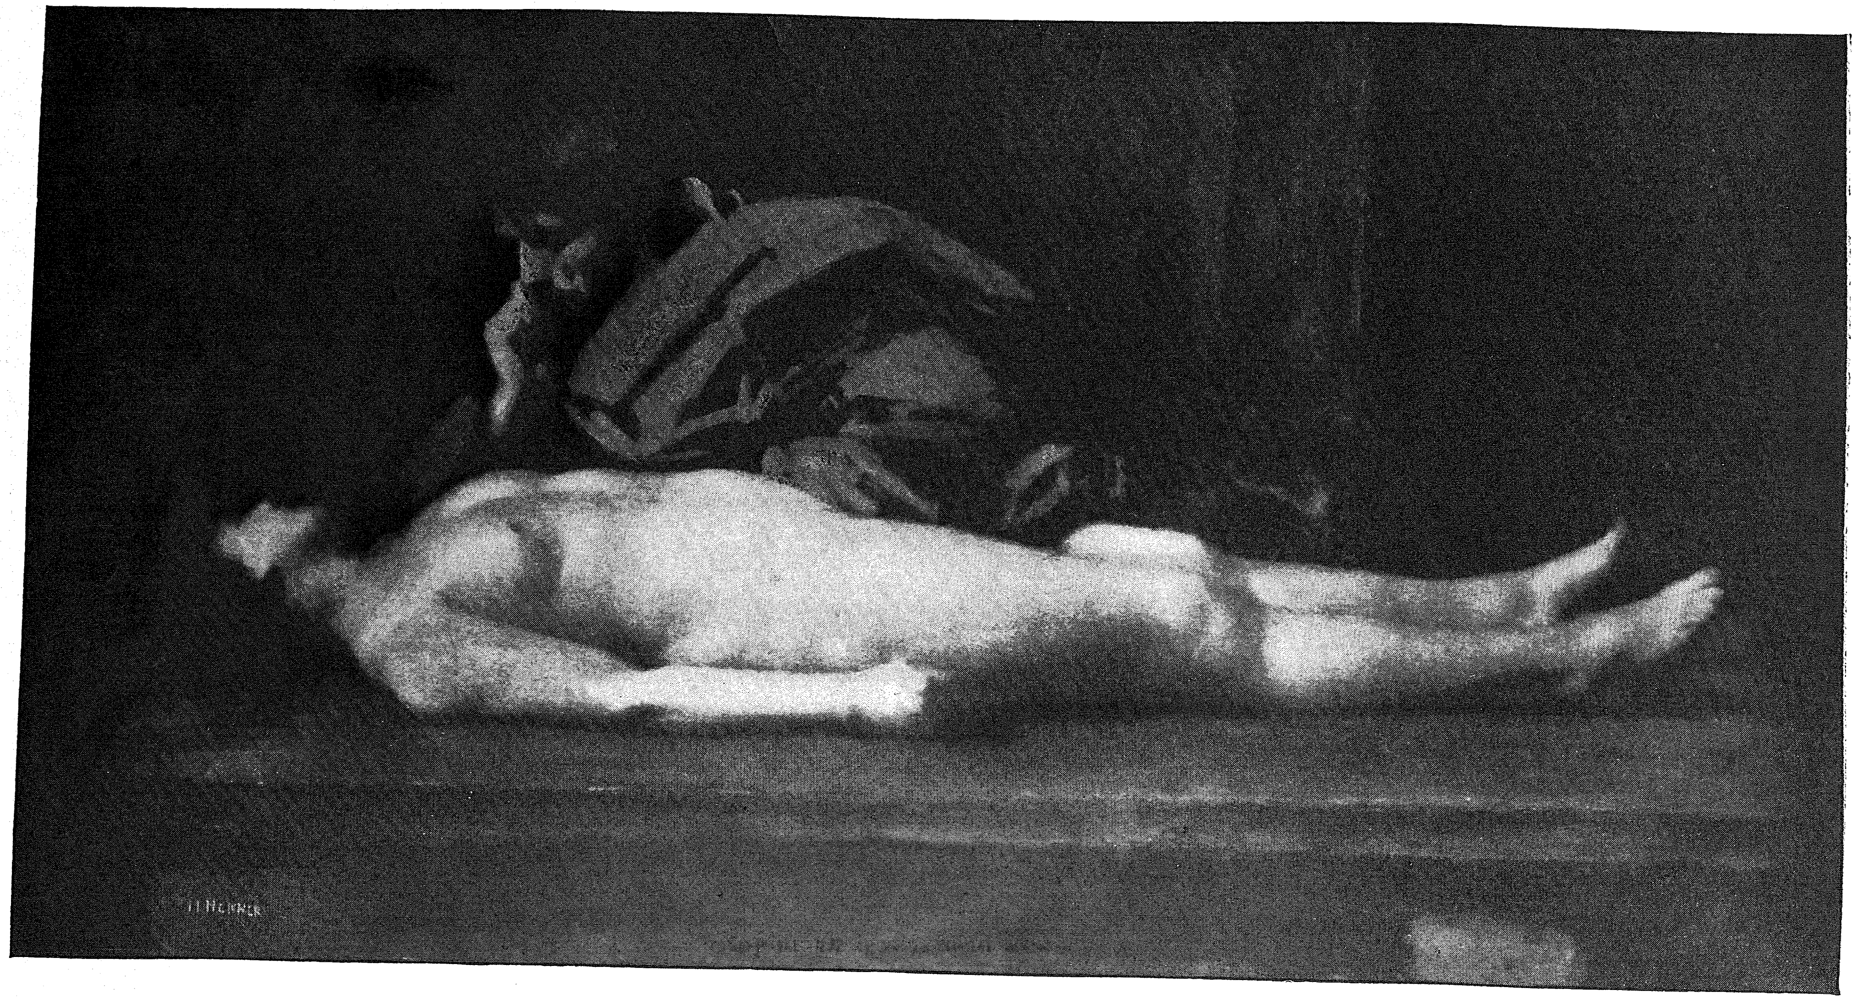
Henderson, capital of Henderson county, Kentucky, U.S.A., on the south bank of the Ohio river, at an altitude of 370 feet. It has three railways—the Louisville and Nashville, the Illinois Central, and the Louisville, Henderson, and St Louis. It has tobacco and cotton factories. Population (1880), 5365; (1900), 10,272, of whom 341 were foreign-born and 4029 were negroes.

Hendon, a suburb of London, in the Harrow parliamentary division of Middlesex, England, on the Brent, 7 miles north-west of St Pancras. The churches are—three Established (St Mary's is old), a Roman Catholic, and several chapels; at Mill Hill also are a Roman Catholic college for the training of missionaries and the well-known grammar school. The Brent reservoir for the Regent Canal occupies 350 acres. Area of civil parish (an urban district), 8382 acres. Population (1881), 10,484; (1901), 22,450.

Hendricks, Thomas Andrews (1819–1885), Vice-President of the United States, was born at Zanesville, Ohio, on the 7th of September 1819. He received a college education, and began in 1843 a successful career at the bar. Identifying himself with the Democratic party, he was sent to Congress in 1851, and from that time till his death was active and prominent in politics. His official service included two terms as representative (1851–55), one as head of the General Land Office (1855–59), one as senator (1863–69), and one as governor of Indiana (1872–76). From 1868 he was put forward for nomination for the Presidency at every Democratic convention save that of 1872. His defeats in 1876 and 1884 by Tilden and Cleveland respectively were followed in each case by his nomination for Vice-President, and in the latter year he was elected; but before the year in which he assumed office (1885) was ended he died at Indianapolis, 25th November.

Henle, Friedrich Gustav Jakob (1809–1885), German pathologist and anatomist, was born on 9th July 1809 at Fürth, in Franconia. After studying medicine at Heidelberg and at Bonn, where he took his doctor's degree in 1832, he became prosector in anatomy to Johannes Müller at Berlin. During the six years he spent in that position he published a large amount of work, including three anatomical monographs on new species of animals, and papers on the structure of the lacteal system, the distribution of epithelium in the human body, the structure and development of the hair, the formation of mucus and pus, &c. In 1840 he accepted the chair of anatomy at Zürich, and in 1844 he was called to Heidelberg, where he taught not only anatomy, but physiology and pathology. About this period he was engaged on his complete system of general anatomy, which formed the sixth volume of the new edition of Sömmering's treatise, published at Leipzig between 1841 and 1844. While at Heidelberg he published a zoological monograph on the sharks and rays, in conjunction with his master Müller, and in 1846 his famous *Manual of Rational Pathology* began to appear; this marked the beginning of a new era in pathological study, since in it physiology and pathology were treated, in Henle's own words, as "branches of one science," and the facts of disease were systematically considered with reference to their physiological relations. In 1852 he moved to Göttingen, whence he issued three years later the first



"The Levite Ephraim." By J. J. Henner.

(*Copyright 1898, by Braun, Clement, and Co.*)

instalment of his great *Handbook of Systematic Human Anatomy*, the last volume of which was not published till 1873. This work was perhaps the most complete and comprehensive of its kind that had so far appeared, and it was remarkable not only for the fulness and minuteness of the anatomical descriptions, but also for the number and excellence of the illustrations with which they were elucidated. During the latter half of his life Henle's researches were mainly histological in character, his investigations embracing the minute anatomy of the blood vessels, serous membranes, kidney, eye, nails, central nervous system, &c. He died at Göttingen on 13th May 1885.

Henley-on-Thames, a municipal borough (incorporated 1883, extended 1892) and market-town in the Henley parliamentary division of Oxfordshire, England, 36 miles to London by rail. The grammar school has been reorganized, and the Henley Blue Coat school incorporated with it. Recent erections are a new town-hall and an isolation hospital. Area, 571 acres. Population (1881), 4601; (1901), 5984. For the regatta, see ROWING.

Henner, Jean Jacques (1829-——), French painter, was born 5th March 1829 at Dornach (Alsace). At first a pupil of Drolling and of Picot, he entered the École des Beaux-Arts in 1848, and took the Prix de Rome with a painting of "Adam and Eve finding the Body of Abel" (1858). At Rome he was guided by Flandrin, and, among other works, painted four pictures for the gallery at Colmar. He first exhibited at the Salon in 1863 a "Bather Asleep," and subsequently contributed "Chaste Susanna" (1865); "Byblis turned into a Spring" (1867); "The Magdalene" (1878); "Portrait of M. Hayem" (1878); "Christ Entombed" (1879); "Saint Jerome" (1881); "Herodias" (1887); "A Study" (1891); "Christ in His Shroud," and a "Portrait of Carolus-Duran" (1896); a "Portrait of Mlle. Fouquier" (1897); "The Levite of the Tribe of Ephraim" (1898), for which a first-class medal was awarded to him (see PLATE); and "The Dream" (1900). Among other professional distinctions Henner also took a Grand Prix for painting at the Paris International Exhibition of 1900. He was made Knight of the Legion of Honour in 1873, Officer in 1878, and Commander in 1889. In 1889 he succeeded Cabanel in the Institut de France.

E. BRICON. *Psychologie d'Art.* Paris, 1900.—C. PHILLIPS. *Art Journal*, 1888.—F. WEDMORE. *Magazine of Art*, 1888.

Henry Maurice, PRINCE OF BATTENBERG (1858–1896), was the third son of Prince Alexander of Hesse and his morganatic wife, the beautiful Countess Julia von Hauke, to whom was granted in 1858 the title of Princess of Battenberg, which her children inherited. He was born at Milan 5th October 1858, was educated with a special view to military service, and in due time became a lieutenant in the first regiment of Rhenish hussars. By their relationship to the grand dukes of Hesse the princes of Battenberg were brought into close contact with the English Court, and Prince Henry paid several visits to England, where he soon became popular both in public and in private circles. It therefore created but little surprise when, towards the close of 1884, it was announced that Queen Victoria had sanctioned his engagement to the Princess Beatrice. The wedding took place at Whippingham on the 23rd of July 1885, and after the honeymoon the prince and princess settled down to a quiet home life with the queen, being seldom absent from the Court, and accompanying her Majesty in her annual visits to the Continent. Three sons and a daughter were the issue of the marriage. On 31st July 1885 a Bill to naturalize Prince Henry was passed by the House of Lords, and he received the title of Royal Highness. He was made a Knight of the Garter and a member of the Privy Council, and also appointed a colonel in the army, and afterwards captain-general and governor of the Isle of Wight and governor of Carisbrooke Castle. He adapted himself very readily to English country life, for he was an excellent shot and an enthusiastic yachtsman. Coming of a martial race, the prince would gladly have embraced an active military career, and when the Ashanti expedition was organized in November 1895 he volunteered to join it. But when the expedition reached Prahsu, about 30 miles from Kumasi, he was struck down by fever, and being promptly conveyed back to the coast, was placed on board H.M.S. *Blonde*. On 17th January he seemed to recover slightly, but a relapse occurred on the 19th, and he died on the evening of the 20th off the coast of Sierra Leone.

Henselt, Adolf von (1814–1889), German composer, was born at Schwabach, in Bavaria, 12th May 1814. At three years old he began to learn the violin, and at five the pianoforte under Frau v. Fladt. On obtaining financial help from Ludwig I. he went to study under Hummel in Weimar, and thence in 1832 to Vienna, where, besides studying composition under Sechter, he made a great success as a concert pianist. In order to recruit his health he made a prolonged tour in 1836 through the chief German towns. In 1837 he settled at Breslau, where he had married, but in the following year he migrated to St Petersburg, where previous visits had made him *persona grata* at Court. He then became Court pianist and inspector of musical studies in the Imperial Institute of Female Education, and was ennobled. In 1852 and again in 1867 he visited England, though in the latter year he made no public appearance. St Petersburg was his home practically until his death, which took place at Warmbrunn on 10th October 1889. The characteristic of Henselt's playing was a combination of Liszt's sonority with Hummel's smoothness. It was full of poetry, remarkable for the great use he made of extended chords, and for his perfect technique. He excelled in his own works and in those of Weber and Chopin. His concerto in F minor is frequently played on the Continent; and of his many valuable studies, *Si oiseau j'étais* is almost hackneyed. His A minor trio deserves to be better known. At one time Henselt was second to Rubinstein in the direction of the St Petersburg Conservatorium.

(R. H. L.)

Henzada, a district of Lower Burma, formerly in the Pegu, but now in the Irrawaddy division. Area, 2886 square miles. Population (1891), 438,131; (1901), 484,774. There were, in 1899, 1329 villages, which paid a revenue of Rs.15,06,834. Of the population 419,639 were Buddhists and Jains, 2781 Hindus, 2364 Mahommedans, and 13,372 Christians, 13,234 of whom were natives, chiefly Karens, besides 4 Parsis and 9 non-Christian Karens. Of a total area of 1,847,040 acres, 459,870 acres were cultivated in 1899, 989,314 acres were not available for cultivation, and 182,829 acres other than fallow were cultivable, but not cultivated. The rainfall in 1898–99, taken at Henzada, was 77·96 inches. The bulk of the cultivation is rice, but 6179 acres were under tobacco. The chief town of the district is HENZADA, which had in 1899 a population of 19,762. It is a municipal town, with ten elective and three *ex-officio* members. It has a third-class district jail, capable of holding 311 prisoners. Other municipal towns in the district are Zalun, with a population of 6006; Myanaung, with a population of 5489; and Kyangin,

with a population of 8116, according to the 1891 census. The village of Lemyethna had a population of 5614. The steamers of the Irrawaddy Flotilla Company call at Henzada and Myanaung. (J. G. SC.)

Heppenheim, a town of Germany, grand-duchy of Hesse-Darmstadt, on the Bergstrasse, between Darmstadt and Heidelberg, 21 miles north of the latter by rail. It possesses a parish church which is reputed to have been built originally by Charlemagne about 805, a large lunatic asylum, and an interesting town hall. On an isolated hill close by stand the extensive ruins of the castle of Starkenburg, built by the abbot of Lorsch in 1064. Hops, wine, and tobacco are grown, and there are large stone quarries. Population (1900), 5777.

Herat.—The Afghan province of Herat, including the valley of the Heri (or Hari) Rud, was carefully surveyed during the progress of the Russo-Afghan Boundary Commission in 1884–85–86, when the dominating fortress of Herat was strengthened and extended for possible defence against Russia. The position of the city was then found to be a little to the south and east of the point previously assigned to it. It lies in 34° 20′ 30″ N. and 62° 11′ 0″ E., at an altitude of 2500 feet above sea-level. The long narrow valley of the Heri Rud, starting from the western slopes of the Koh-i-Baba, extends almost due west for 300 miles before it takes its great northern bend at Kuhsán, and passes northwards through the broken ridges of the Siah Bubuk (the western extremity of the range which we now call Paropamisus) towards Sarakhs. For the greater part of its length it drains the southern slopes only of the Paropamisus and the northern slopes of a parallel range called Koh-i-Safed. The Paropamisus forms the southern face of the Turkestan plateau, which contains the sources of the Murghab river; the northern face of the same plateau is defined by the Band-i-Turkestan. On the south of the plateau we find a similar succession of narrow valleys dividing parallel flexures, or anticlinals, formed under similar geological conditions to those which appear to be universally applicable to the Himalaya, the Hindu Kush, and the Indus frontier mountain systems. From one of these long lateral valleys the Heri Rud receives its principal tributary, which joins the main river below Obeh, 180 miles from its source; and it is this tributary (separated from the Heri Rud by the narrow ridges of the Koh-i-Safed and Band-i-Baián) that offers the high road from Herat to Kabul, and not the Heri Rud itself. From its source to Obeh the Heri Rud is a valley of sandy desolation. There are no glaciers near its sources, although they must have existed there in geologically recent times, but masses of melting snow annually give rise to floods, which rush through the midst of the valley in a turbid red stream, frequently rendering the river impassable and cutting off the crazy brick bridges at Herat and Tirpul. It is impossible, whilst watching the rolling, seething volume of flood-water which swirls westwards in April, to imagine the waste stretches of dry river bed which in a few months' time (when every available drop of water is carried off for irrigation) will represent the Heri Rud. The soft shales or clays, of the hills bounding the valley render these hills especially subject to the action of denudation, and the result, in rounded slopes and easily accessible crests, determines the nature of the easy tracks and passes which intersect them. At the same time, any excessive local rainfall is productive of difficulty and danger from the floods of liquid mud and loose boulders which sweep like an avalanche down the hill sides. It was a sudden storm of this nature which led to the disaster on the Chashma Sabz pass in April 1885, when the British Boundary Commission lost a company of mule-drivers and much valuable property. The intense cold which usually accompanies these sudden northern blizzards of Herat and Turkestan is a further source of danger.

From Obeh, 50 miles east of Herat, the cultivated portion of the valley commences, and it extends, with a width which varies from 8 to 16 miles, to Kuhsán, 60 miles west of the city. But the great stretch of highly irrigated and valuable fruit-growing land, which appears to spread from the walls of Herat east and west as far as the eye can reach, and to sweep to the foot of the hills north and south with an endless array of vineyards and melon-beds, orchards and villages, varied with a brilliant patchwork of poppy growth brightening the width of green wheat-fields with splashes of scarlet and purple—all this is really comprised within a narrow area which does not extend beyond a ten-miles' radius from the city. The system of irrigation by which these agricultural results are attained is most elaborate. The despised Herati Tajak, in blue shirt and skull-cap, and with no instrument better than a three-cornered spade, is as skilled an agriculturist as is the Ghilzai engineer, but he cannot effect more than the limits of his water-supply will permit. He adopts the Karez (or, Persian, *Kanát*) system of underground irrigation, as does the Ghilzai in Afghanistan, and brings every drop of water that he can find to the surface; but it cannot be said that he is more successful than the Ghilzai. It is the startling contrast of the Herati oasis with the vast expanse of comparative sterility that encloses it which has given such a fictitious value to the estimates of the material wealth of the valley of the Heri Rud.

The valley about Herat includes a flat alluvial plain which might, for some miles on any side except the north, be speedily reduced to an impassable swamp by means of flood-water from the surrounding canals. Three miles to the south of the city the river flows from east to west, spanned by the Pal-i-Malún, a bridge possessing grand proportions, but which was in 1885 in a state of grievous disrepair and practically useless. East and west stretches the long vista of the Heri Rud. Due north the hills called the Koh-i-Mulla Khwaja appear to be close and dominating, but the foot of these hills is really about 3 miles distant from the city. Under the shadow of them stands the world-famed Ziarat of Gazargarh, the last resting-place of the greatest of Afghan rulers, Dost Mahomed Khan. This northern line of barren, broken sandstone hills is geographically no part of the Paropamisus range, from which it is separated by a stretch of sandy upland about 20 miles in width, called the Dasht-i-Hamdamao, or Dasht-i-Ardewán, formed by the talus or drift of the higher mountains, which, washed down through centuries of denudation, now forms long sweeping spurs of gravel and sand, scantily clothed with wormwood scrub and almost destitute of water. Through this stretch of *dasht* the drainage from the main water-divide breaks downwards to the plains of Herat, where it is arrested and utilized for irrigation purposes. To the north-east of the city a very considerable valley has been formed between the Paropamisus and the subsidiary Koh-i-Mulla Khwaja range, called Korokh. Here there are one or two important villages and a well-known shrine marked by a group of pine trees which is unique in this part of Afghanistan. The valley leads to a group of passes across the Paropamisus into Turkestan, of which the Zirmast is perhaps the best known.

Paropamisus.—The main water-divide between Herat and the Turkestan Chol (the loess district) has been called Paropamisus for want of any well-recognized general

name. To the north of the Korokh valley it exhibits something of the formation of the Hindu Kush (of which it is apparently a geological extension), but as it passes westwards it becomes broken into fragments by processes of denudation, until it is hardly recognizable as a distinct range at all. The direct passes across it from Herat (the Baba and the Ardewán) wind amongst masses of disintegrating sandstone for some miles on each side of the dividing water-shed, but farther west the rounded knolls of the rain-washed downs may be crossed almost at any point without difficulty. The names applied to this débris of a once formidable mountain system are essentially local and hardly distinctive. Beyond this range the sand and clay loess formation spreads downwards like a tumbled sea, hiding within the folds of its many-crested hills the twisting course of the Kushk and its tributaries.

Kushk.—The exact position of Herat, with reference to the Russian station of Kushk (now the terminus of a branch railway from Merv), is as follows:—From Herat, a gentle ascent northwards for 3 miles reaches to the foot of the Koh-i-Mulla Khwaja, crossing the Jui Nao or "new" canal, which here divides the gravel-covered foot hills from the alluvial flats of the Heri Rud plain. The crest of the outer ridges of this subsidiary range is about 700 feet above the city, at a distance of 4 miles from it. For 28 miles farther the road winds first amongst the broken ridges of the Koh-i-Mulla Khwaja, then over the intervening *dasht* into the southern spurs of the Paropamisus to the Ardewán pass. This is the highest point it attains, and it has risen about 2150 feet from Herat. From the pass it drops over the gradually decreasing grades of a wide sweep of Chol (which here happens to be locally free from the intersecting network of narrow ravines which is generally a distinguishing feature of Turkestan loess formations) for a distance of 35 miles into the Russian railway station, falling some 2700 feet from the crest of the Paropamisus.

City and Fortress of Herat.—The city and fortress of Herat were found in 1885 to differ in no very material degree from the city and fortress of 1845, and the description given in the ninth edition of this work is still fairly accurate. The bazaar was poor in 1885, and trade was slack. Even in the streets converging on the Charsu lines of shops were closed and business was at a standstill; but never, in the most flourishing circumstances, could the markets of Herat have ever rivalled those of Kandahar or Kabul. Within the walls of the city there is not a building which can claim any architectural distinction; the streets are narrow, closed in with high walls, and unutterably filthy; many of the highways are but tunnels, with roofs sagging beneath a weight of overcrowded mud tenements. So poor was the trade of the Herat bazaar that the business introduced by the Afghan Boundary Commission made a most appreciable difference in its appearance. By the spring of 1886 the shops were gay with Bokhara embroideries and silks and the carpets of Adraskand and Turkestan; the roof of the Charsu was almost in a state of repair, whilst a whole streetful of shopkeepers had again taken down their shutters and resumed business.

When the Royal Engineers of the Russo-Afghan Boundary Commission entered Herat in 1885 they found its defences in various stages of disrepair. The gigantic rampart was unflanked, and the covered ways in the face of it subject to enfilade from end to end. The ditch was choked, the gates were unprotected; the tumbled mass of irregular mud buildings which constituted the city clung tightly to the walls; there were no gun emplacements. Outside, matters were almost worse than inside. To the north of the walls the site of old Herat was indicated by a vast mass of débris—mounds of bricks and pottery intersected by a network of shallow trenches, where the only semblance of a protective wall was the irregular line of the Tal-i-Bangi. South of the city was a vast area filled in with the graveyards of centuries. Here the trenches dug by the Persians during the last siege were still in a fair state of preservation; they were within a stone's-throw of the walls. Round about the city on all sides were similar opportunities for close approach; even the villages stretched out long irregular streets towards the city gates. To the north-west, beyond the Tal-i-Bangi, the magnificent outlines of the Mosalla filled a wide space with the glorious curves of dome and gateway and the stately grace of tapering minars, but the impressive beauty of this, by far the finest architectural structure in all Afghanistan, could not be permitted to weigh against the fact that the position occupied by this pile of solid buildings was fatal to the interests of effective defence. By the end of August 1885, when a political crisis had supervened between Great Britain and Russia, under the orders of the Amir the Mosalla was destroyed; but four minars standing at the corners of the wide plinth still remain to attest to the glorious proportions of the ancient structure, and to exhibit samples of that decorative tilework, which for intricate beauty of design and exquisite taste in the blending of colour still appeals to the memory as unique. At the same time the ancient graveyards round the city were swept smooth and levelled; obstructions were demolished, outworks constructed, and the defences generally renovated. Whether or no the strength of this bulwark of North-Western Afghanistan should ever be practically tested, the general result of the most recent investigations into the value of Herat as a strategic centre has been largely to modify the once widely-accepted view that the key to India lies within it.

Since the Afghan Boundary Commission visited Herat very little has been written about it. Major C. E. YATE's *Northern Afghanistan* (London, 1888) contains much general information; but the exhaustive reports of the Boundary Commission have not been published. The above description is compiled from unpublished notes. (T. H. H*.)

Hérault, a department in the south of France, washed by the Mediterranean and traversed by the Cevennes mountains.

Area, 2403 square miles. The population increased from 439,044 in 1886 to 469,684 in 1896, and to 488,285 in 1901. Births in 1899 numbered 10,357, of which 526 were illegitimate, against 10,517 deaths; marriages numbered 3646. The department had in 1896 989 schools, with 56,000 pupils, and its illiterates form less than 1 per cent. of the population. The surface under cultivation amounts to 1,008,226 acres, of which 306,420 acres are arable and 415,150 acres vineyards. Hérault takes the first place among the departments for the manufacture of wine, as well for the abundance of its production, exceeding in 1899 12,300,000 hectolitres (270,600,000 gallons), as for its quality, which gave to the production the value of £9,393,000. Cereals and grass lands, on the other hand, give a very poor return, the olive yielding in 1899 £66,000, and the mulberry £7300; both thrive in this department, which also in 1898 produced 2451 cwts. of silk-worm cocoons. The live stock includes 22,130 horses, 10,610 mules, 6300 asses, 8360 cattle, 349,170 sheep, 20,000 goats, and 17,000 pigs. The mining industry in 1898 produced 201,000 metric tons of coal, 4000 tons of iron, and the salt-pans yielded 40,000 tons of salt. The industry in metals has, however, no large establishments. The distilleries manufactured in 1898 438,000 gallons of alcohol. The most populated places are Montpellier, the capital, with 76,364 inhabitants in 1901; Béziers, 52,077; and Cette, 33,065.

Heredia, José Maria de (1842- ——), the modern master of the French sonnet, was born at Fortuna Cafeyere, near Santiago de Cuba, on the 22nd November 1842, being in blood part Spanish Creole and part French. At the age of eight he came from the West Indies to

France, returning thence to Havana at seventeen, and finally making France his home not long afterwards. For some time he studied at the École des Chartes. In the later 'sixties, with M. Coppée, M. Sully-Prudhomme, Verlaine, and others less distinguished, he made one of the band of poets who gathered round Leconte de Lisle and took, or accepted, the name of Parnassiens. To this new school, form—the technical side of their art—was of supreme importance, and, in reaction against the influence of Musset, they rigorously repressed in themselves all personal feeling and emotion. "True poetry," said M. de Heredia in his discourse on entering the Academy—"true poetry dwells in nature and in humanity, which are eternal, and not in the heart of the creature of a day, however great." M. de Heredia's place in the movement was soon assured. He wrote very little, and published even less, but his sonnets circulated in MS., and gave him a reputation before they appeared in 1893, together with a few longer poems, as a volume, under the title of *Les Trophées*. He was elected to the Academy on the 22nd February 1894, in the place of Mazade, the publicist. Few purely literary men can have entered the Academy with credentials so small in quantity. A small volume of verse—a translation, with introduction, of Diaz del Castillo's *History of the Conquest of New Spain* (1878-81)—a translation of the life of the nun Alferez (1894), De Quincey's "Spanish Military Nun"—and one or two short pieces of occasional verse, and an introduction or so—this is but small literary baggage, to use the French expression. But the sonnets are of their kind among the most superb in modern literature. "A *Légende des siècles* in sonnets" M. Coppée has called them. Each presents a picture, striking, brilliant, drawn with unfaltering hand—the picture of some characteristic scene in man's long history. The verse is flawless, polished like a gem; and its sound has distinction and fine harmony. If one may suggest a fault, it is that each picture is sometimes too much of a picture only, and that the poetical line, like that of M. de Heredia's master, Leconte de Lisle himself, is occasionally overcrowded. M. de Heredia is none the less one of the most skilful craftsmen who have ever practised the art of verse.

Heredity.—Heredity is the name given to the generalization, drawn from the observed facts, that animals and plants closely resemble their progenitors. (That the resemblance is not complete involves in the first place the subject of Variation (*q.v.*); but it must be clearly stated that there is no adequate ground for the current loose statements as to the existence of opposing "laws" or "forces" of heredity and variation.) In the simplest cases there seems to be no separate problem of heredity. When a creeping plant propagates itself by runners, when a Nais or Myrianida breaks up into a series of similar segments, each of which becomes a worm like the parent, we have to do with the general fact that growing organisms tend to display a symmetrical repetition of equivalent parts, and that reproduction by fission is simply a special case of metamerism. When we try to answer the question why the segments of an organism resemble one another, whether they remain in association to form a segmented animal, or break into different animals, we come to the conclusion, which at least is on the way to an answer, that it is because they are formed from pieces of the same protoplasm, growing under similar conditions. It is apparently a fundamental property of protoplasm to be able to multiply by division into parts, the properties of which are similar to each other and to those of the parent.

This leads us directly to the cases of reproduction where there is an obvious problem of heredity. In the majority of cases among animals and plants the new organisms arise from portions of living matter, separated from the parents, but different from the parents in size and structure. These germs of the new organisms may be spores, reproductive cells, fused reproductive cells, or multicellular masses (see REPRODUCTION). For the present purpose it is enough to state that they consist of nucleated masses of protoplasm known as cells. These pass through an embryological history, in which by growth, multiplication, and specialization they form structures closely resembling the parents. Now, if it could be shown that these reproductive masses arose directly from the reproductive masses which formed the parent body, the problems of heredity would be extremely simplified. If the first division of a reproductive cell set apart one mass to lie dormant for a time and ultimately to form the reproductive cells of the new generation, while the other mass, exactly of the same kind, developed directly into the new organism, then heredity would simply be a delayed case of what is called organic symmetry, the tendency of similar living material to develop in similar ways under the stimulus of similar external conditions. The cases in which this happens are very rare. In the Diptera the first division of the egg-cell separates the nuclear material of the subsequent reproductive cells from the material that is elaborated into the new organism to contain these cells. In the Daphnidæ and in Sagitta a similar separation occurs at slightly later stages; in Vertebrates it occurs much later; while in some Hydroids the germ-cells do not arise in the individual which is developed from the egg-cell at all, but in a much later generation, which is produced from the first by budding. However, it is not necessary to dismiss the fertile idea of what Nussbaum and Weismann, who drew attention to it, called "continuity of the germ-plasm." Weismann has shown that an actual series of organic forms might be drawn up in which the formation of germ-cells begins at stages successively more remote from the first division of the egg-cell. He has also shown evidence, singularly complete in the case of the Hydroids, for the existence of an actual migration of the place of formation of the germ-cells, the migration reaching farther and farther from the egg-cell. He has elaborated the conception of the germ-track, a chain of cell generations in the development of any creature along which the reproductive material saved over from the development of one generation for the germ-cells of the next generation is handed on in a latent condition to its ultimate position. And thus he supposes a real continuity of the germ-plasm, extending from generation to generation in spite of the apparent discontinuity in the observed cases. The conception certainly ranks among the most luminous and most fertile contributions of the 19th century to biological thought, and it is necessary to examine at greater length the superstructure which Weismann has raised upon it.

Weismann's Theory of the Germ-plasm.—A living being takes its individual origin only where there is separated from the stock of the parent a little piece of the peculiar reproductive plasm, the so-called germ-plasm. In sexless reproduction one parent is enough; in sexual reproduction equivalent masses of germ-plasm from each parent combine to form the new individual. The germ-plasm resides in the nucleus of cells, and Weismann identifies it with the nuclear material named chromatin. Like ordinary protoplasm, of which the bulk of cell bodies is composed, germ-plasm is a living material, capable of growing in bulk without alteration of structure when it is supplied with appropriate food. But it is a living material much more complex than protoplasm. In the first place, the mass of germ-plasm which is the starting-point of a new individual consists of several, sometimes of many, pieces named "idants," which are the chromosomes, into

a definite number of which the nuclear material of a dividing cell breaks up. These idants are a collection of "ids," which Weismann tentatively identifies with the microsomata contained in the chromosomes, which are visible after treatment with certain reagents. Each id contains all the possibilities—generic, specific, individual —of a new organism, or rather the directing substance which in appropriate surroundings of food, &c., forms a new organism. Each id is a veritable microcosm, possessed of a historic architecture that has been elaborated slowly through the multitudinous series of generations that stretch backwards in time from every living individual. This microcosm, again, consists of a number of minor vital units called "determinants," which cohere according to the architecture of the whole id. The determinants are hypothetical units corresponding to the number of parts of the organism independently variable. Lastly, each determinant consists of a number of smaller hypothetical units, the "biophores." These are adaptations of a conception of De Vries, and are supposed to become active by leaving the nucleus of the cell in which they lie, passing out into the general protoplasm of the cell and ruling its activities. Each new individual begins life as a nucleated cell, the nucleus of which contains germ-plasm of this complex structure derived from the parent. The reproductive cell gives rise to the new individual by continued absorption of food, by growth, cell-divisions, and cell-specializations. The theory supposes that the first divisions of the nucleus are "doubling," or homogeneous divisions. The germ-plasm has grown in bulk without altering its character in any respect, and, when it divides, each resulting mass is precisely alike. From these first divisions a chain of similar doubling divisions stretches along the "germ-tracks," so marshalling unaltered germ-plasm to the generative organs of the new individual, to be ready to form the germ-cells of the next generation. In this mode the continuity of the germ-plasm from individual to individual is maintained. This also is the immortality of the germ-cells, or rather of the germ-plasm, the part of the theory which has laid so large a hold on the popular imagination, although it is really no more than a reassertion in new terms of biogenesis. With this also is connected the celebrated denial of the inheritance of acquired characters. It seemed a clear inference that, if the hereditary mass for the daughters were separated off from the hereditary mass that was to form the mother, at the very first, before the body of the mother was formed, the daughters were in all essentials the sisters of their mother, and could take from her nothing of any characters that might be impressed on her body in subsequent development. In the later elaboration of his theory Weismann has admitted the possibility of some direct modification of the germ-plasm within the body of the individual acting as its host.

The mass of germ-plasm which is not retained in unaltered form to provide for the generative cells is supposed to be employed for the elaboration of the individual body. It grows, dividing and multiplying, and forms the nuclear matter of the tissues of the individual, but the theory supposes this process to occur in a peculiar fashion. The nuclear divisions are what Weismann calls "differentiating" or heterogeneous divisions. In them the microcosms of the germ-plasm are not doubled, but slowly disintegrated in accordance with the historical architecture of the plasm, each division differentiating among the determinants and marshalling one set into one portion, another into another portion. There are differences in the observed facts of nuclear division which tend to support the theoretical possibility of two sorts of division, but as yet these have not been correlated definitely with the divisions along the germ-tracks and the ordinary divisions of embryological organogeny. The theoretical conception is, that when the whole body is formed, the cells contain only their own kind of determinants, and it would follow from this that the cells of the tissues cannot give rise to structures containing germ-plasm less disintegrated than their own nuclear material, and least of all to reproductive cells which must contain the undisintegrated microcosms of the germ-plasm. Cases of bud-formation and of reconstructions of lost parts (see REGENERATION) are regarded as special adaptations made possible by the provision of latent groups of accessory determinants, to become active only on emergency.

It is to be noticed that Weismann's conception of the processes of ontogeny is strictly evolutionary, and in so far is a reversion to the general opinion of biologists of the 17th and 18th centuries. These supposed that the germ-cell contained an image-in-little of the adult, and that the process of development was a mere unfolding or evolution of this, under the influence of favouring and nutrient forces. Hartsoeker, indeed, went so far as to figure the human spermatozoon with a mannikin seated within the "head," and similar extremes of imagination were indulged in by other writers for the spermatozoon or ovum, according to the view they took of the relative importance of these two bodies. Wolff, in his *Theoria Generationis* (1759), was the first distinguished anatomist to make assault on these evolutionary views, but his direct observations on the process of development were not sufficient in bulk nor in clarity of interpretation to convince his contemporaries. Naturally the improved methods and vastly greater knowledge of modern days have made evolution in the old sense an impossible conception; we know that the egg is morphologically unlike the adult, that various external conditions are necessary for its subsequent progress through a slow series of stages, each of which is unlike the adult, but gradually approaching it until the final condition is reached. None the less, Weismann's theory supposes that the important determining factor in these gradual changes lies in the historical architecture of the germ-plasm, and from the theoretical point of view his theory remains strictly an unfolding, a becoming manifest of hidden complexity.

Hertwig's View.—The chief modern holder of the rival view, and the writer who has put together in most cogent form the objections to Weismann's theory, is Oscar Hertwig. He points out that there is no direct evidence for the existence of differentiating as opposed to doubling divisions of the nuclear matter, and, moreover, he thinks that there is very generally diffused evidence as to the universality of doubling division. In the first place, there is the fundamental fact that single-celled organisms exhibit only doubling division, as by that the persistence of species which actually occurs alone is possible. In the case of higher plants, the widespread occurrence of tissues with power of reproduction, the occurrence of budding in almost any part of the body in lower animals and in plants, and the widespread powers of regeneration of lost parts, are easily intelligible if every cell like the egg-cell has been formed by doubling division, and so contains the germinal material for every part of the organism, and thus, on the call of special conditions, can become a germ-cell again. He lays special stress on those experiments in which the process of development has been interfered with in various ways at various stages, as showing that the cells which arise from the division of the egg-cell were not predestined unalterably for a particular rôle, according to a predetermined plan. He dismisses Weismann's suggestion of the presence of accessory determinants which remain latent unless they happen to be required,

as being too complicated a supposition to be supported without exact evidence, a view in which he has received strong support from those who have worked most at the experimental side of the question. From consideration of a large number of physiological facts, such as the results of grafting, transplantations of tissues, and transfusions of blood, he concludes that the cells of an organism possess, in addition to their patent microscopical characters, latent characters peculiar to the species, and pointing towards a fundamental identity of the germinal substance in every cell.

The Nuclear Matter.—Apart from these two characteristic protagonists of extreme and opposing views, the general consensus of biological opinion does not take us very far beyond the plainest facts of observation. The resemblances of heredity are due to the fact that the new organism takes its origin from a definite piece of the substance of its parent or parents. This piece always contains protoplasm, and as the protoplasm of every animal and plant appears to have its own specific reactions, we cannot exclude this factor; indeed many, following the views of Verworn, and seeing in the specific metabolisms of protoplasm a large part of the meaning of life, attach an increasing importance to the protoplasm in the hereditary mass. Next, it always contains nuclear matter, and, in view of the extreme specialization of the nuclear changes in the process of maturation and fertilization of the generative cells, there is more than sufficient reason for believing that the nuclear substance, if not actually the specific germ-plasm, is of vast importance in heredity. The theory of its absolute dominance depends on a number of experiments, the interpretation of which is doubtful. Nussbaum showed that in Infusoria non-nucleated fragments of a cell always died, while nucleated fragments were able to complete themselves; but it may be said with almost equal confidence that nuclei separated from protoplasm also invariably die—at least, all attempts to preserve them have failed. Hertwig and others, in their brilliant work on the nature of fertilization, showed that the process always involved the entrance into the female cell of the nucleus of the male cell, but we now know that part of the protoplasm of the spermatozoon also enters. Boveri made experiments on the cross-fertilization of non-nucleated fragments of the eggs of *Sphærechinus granularis* with spermatozoa of *Echinus microtuberculatus*, and obtained dwarf larvæ with only the paternal characters; but the nature of his experiments was not such as absolutely to exclude doubt. Finally, in addition to the nucleus and the protoplasm, another organism of the cell, the centrosome, is part of the hereditary mass. In sum, while most of the evidence points to a preponderating importance of the nuclear matter, it cannot be said to be an established proposition that the nuclear matter is the germ-plasm. Nor are we yet definitely in a position to say that the germinal mass (nuclear matter, protoplasm, &c., of the reproductive cells) differs essentially from the general substance of the organism—whether, in fact, there is continuity of *germ-plasm* as opposed to continuity of living material from individual to individual. The origin of sexual cells from only definite places, in the vast majority of cases, and such phenomena as the phylogenetic migration of their place of origin among the Hydromedusæ, tell strongly in favour of Weismann's conception. Early experiments on dividing eggs, in which, by separation or transposition, cells were made to give rise to tissues and parts of the organism which in the natural order they would not have produced, tell strongly against any profound separation between germ-plasm and body-plasm. It is also to be noticed that the failure of germ-cells to arise except in specific places may be only part of the specialized ordering of the whole body, and does not necessarily involve the interpretation that reproductive material is absolutely different in kind.

Amphimixis.—Hitherto we have considered the material bearer of heredity apart from the question of sexual union, and we find that the new organism takes origin from a portion of living matter, forming a material which may be called germ-plasm, in which resides the capacity to correspond to the same kind of surrounding forces as stimulated the parent germ-plasm by growth of the same fashion. In many cases (*e.g.*, asexual spores) the piece of germ-plasm comes from one parent, and from an organ or tissue not associated with sexual reproduction; in other cases (parthenogenetic eggs) it comes from the ovary of a female, and may have the apparent characters of a sexual egg, except that it develops without fertilization. In such cases the problem of heredity does not differ fundamentally from the symmetrical repetition of parts. In most of the higher plants and animals, however, sexual reproduction is the normal process, and from our present point of view the essential feature of this is that the germ-plasm which starts the new individual (the fertilized egg) is derived from the male (the spermatozoon) and from the female parent (the ovum). Although it cannot yet be set down sharply as a general proposition, there is considerable evidence to show that in the preparation of the ovum and spermatozoon for fertilization the nuclear matter of each is reduced by half (reducing division of the chromosomes), and that fertilization means the restoration of the normal bulk in the fertilized cell by equal contributions from male and female. So far as the known facts of this process of union of germ-plasms go, they take us no farther than to establish such a relation between the offspring and two parents as exists between the offspring and one parent in the other cases. Amphimixis has a vast importance in the theory of evolution (Weismann, for instance, regards it as the chief factor in the production of variations); for its relation to heredity we are as yet dependent on empirical observations.

Heredity and Development.—The actual process by which the germinal mass slowly assumes the characters of the adult—that is, becomes like the parent—depends on the interaction of two sets of factors: the properties of the germinal material itself, and the influences of substances and conditions external to the germinal material. Naturally, as Naegeli and Hertwig in particular have pointed out, there is no perpetual sharp contrast between the two sets of factors, for, as growth proceeds, the external is constantly becoming the internal; the results of influences, which were in one stage part of the environment, are in the next and subsequent stages part of the embryo. The differences between the exponents of evolution and epigenesis offer practical problems to be decided by experiment. Every phenomenon in development that is proved the direct result of epigenetic factors can be discounted from the complexity of the germinal mass. If, for instance, as Driesch and Hertwig have argued, much of the differentiation of cells and tissues is a function of locality and is due to the action of different external forces on similar material, then just so much burden is removed from what evolutionists have to explain. That much remains cannot be doubted. Two eggs similar in appearance develop side by side in the same sea-water, one becoming a mollusc, the other an Amphioxus. Hertwig would say that the slight differences in the original eggs would determine slight differences in metabolism and so forth, with the result that the segmentation of the two is slightly different; in the next stage the differences in metabolisms and other relations will be increased, and so on indefinitely. But in such cases *c'est le premier pas qui coûte*, and the absolute cost in theoretical complexity of

the germinal material can be estimated only after a prolonged course of experimental work in a field which is as yet hardly touched.

Empirical Study of Heredity.—The fundamental basis of heredity is the separation of a mass from the parent (germ-plasm) which under certain conditions grows into an individual resembling the parent. The goal of the study of heredity will be reached only when all the phenomena can be referred to the nature of the germ-plasm and of its relations to the conditions under which it grows, but we have seen how far our knowledge is from any attempt at such references. In the meantime, the empirical facts, the actual relations of the characters in the offspring to the characters of the parents and ancestors, are being collected and grouped. In this inquiry it at once becomes obvious that every character found in a parent may or may not be present in the offspring. When any character occurs in both, it is generally spoken of as transmissible and of having been transmitted. In this broad sense there is no character that is not transmissible. In all kinds of reproduction, the characters of the class, family, genus, species, variety or race, and of the actual individual, are transmissible, the certainty with which any character appears being almost in direct proportion to its rank in the descending scale from order to individual. The transmitted characters are anatomical, down to the most minute detail; physiological, including such phenomena as diatheses, timbre of voice, and even compound phenomena, such as gaucherie and peculiarity of handwriting; psychological; pathological; teratological, such as syndactylism and all kinds of individual variations. Either sex may transmit characters which in themselves are necessarily latent, as, for instance, a bull may transmit a good milking strain. In forms of asexual reproduction, such as division, budding, propagation by slips, and so forth, every character of the parent may appear in the descendant, and apparently even in the descendants produced from that descendant by the ordinary sexual processes. In reproduction by spore formation, in parthenogenesis and in ordinary sexual modes, where there is an embryological history between the separated mass and the new adult, it is necessary to attempt a difficult discrimination between acquired and innate characters.
